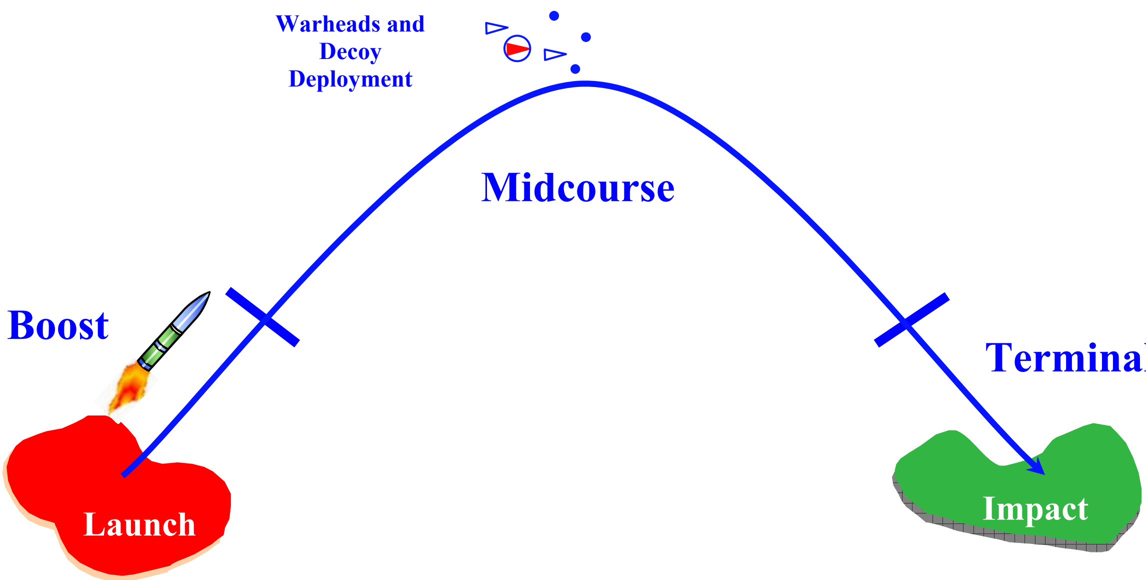
The public comment period began with the publication of the Notice of Availability (NOA) on September 17, 2004 in the FR by the Environmental Protection Agency (EPA). The NOA announced the availability of the Draft PEIS and requested comments on it. A downloadable version of the Draft PEIS was available on the BMDS PEIS web site and hardcopies of the document were placed in public libraries in the cities holding the public hearings. In October, 2004 MDA held public hearings in Arlington, Virginia; Sacramento, California; Anchorage, Alaska; and Honolulu, Hawaii. The MDA also placed legal notices in local and regional newspapers and notified state representatives of the public hearings. The purpose of these hearings was to solicit comments on the environmental areas analyzed and considered in the Draft PEIS. Appendix B contains a detailed description of the public comment period and a reproduction of the transcripts of the public hearings. The MDA's consideration of the approximately 8,500 comments received on the Draft PEIS and responses to in-scope comments can be found in Appendix K of this PEIS. Additional areas of analysis—orbital debris, perchlorate, and radar impacts to wildlife—are addressed in more technical detail in Appendices L, M, and N. The Final BMDS PEIS will be available for download at the site address listed above.

The Proposed BMDS

Conceptually, the BMDS would be a layered system of defensive weapons (i.e., lasers and interceptors); sensors (i.e., radars, infrared, optical, and lasers); Command and Control, Battle Management, and Communications (C2BMC); and support assets (i.e., auxiliary equipment, infrastructure and test assets); each with specific functional

capabilities, working together to defend against all classes and ranges of threat ballistic missiles in the three flight phases. A flight phase is a portion of the path taken by a threat missile moving through the atmosphere or space. The three flight phases of a ballistic missile are boost, midcourse, and terminal. Exhibit ES-1 describes these three phases. Multiple defensive weapons would be used to create a layered defense comprised of multiple intercept opportunities.

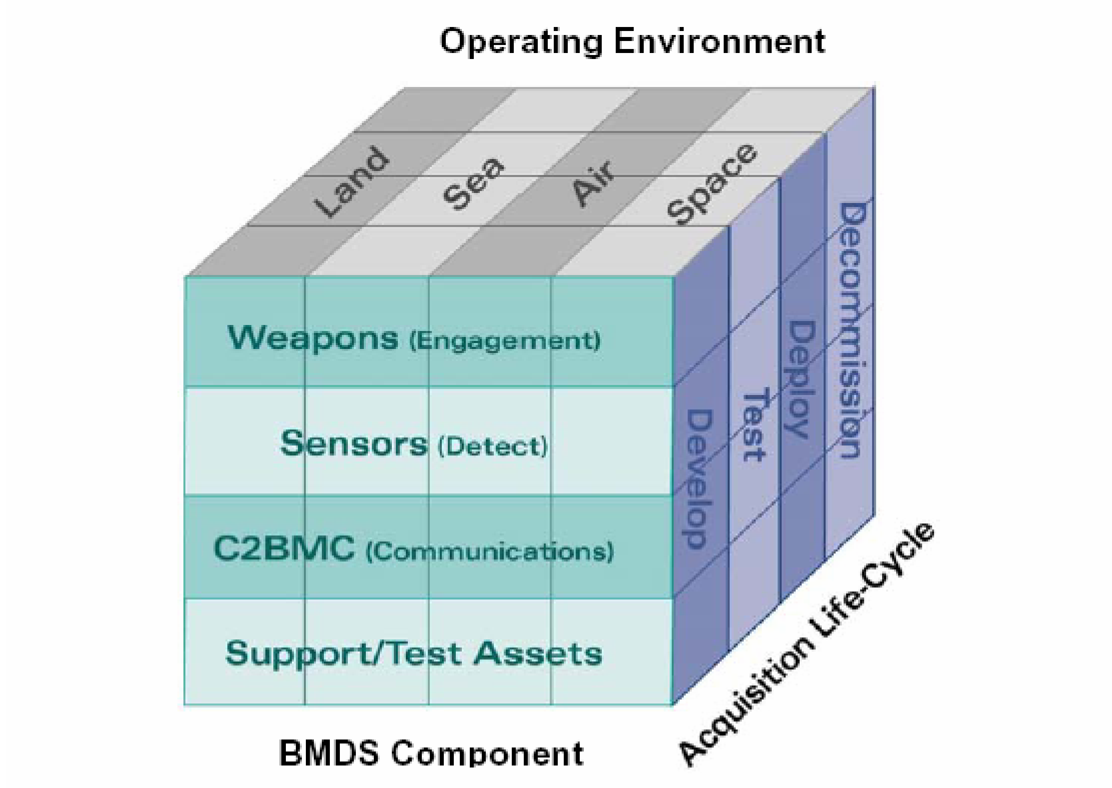
Exhibit ES-1. Ballistic Missile Flight Phases



Flight Phase	Description
Boost	First phase - rocket engine is ignited, missile lifts off and sets out on a specific path.
Midcourse	Second phase - begins when the rocket engine cuts off and the missile continues on a ballistic trajectory. Warheads and decoys may be deployed in this phase.
Terminal	Third phase - final portion of a ballistic trajectory between the midcourse phase and trajectory termination.

To determine environmental impacts, this PEIS analyzes the proposed BMDS in terms of its components, i.e., weapons, sensors, C2BMC, and support assets. These components become part of the BMDS through the acquisition life cycle phases – develop, test, deploy, and decommission. The components and activities could occur in various land, sea, air, and space operating environments. Exhibit ES-2 depicts the multi-dimensional complexities involved in considering the impacts of implementing an integrated BMDS.

Exhibit ES-2. Complexities of an Integrated BMDS



Components of the BMDS

The proposed BMDS would be comprised of components, i.e., weapons, sensors, C2BMC, and support assets. These are the systems and subsystems of logically grouped hardware and software that perform interacting tasks to provide BMDS functional capabilities. Historically, MDA primarily focused on developing stand-alone elements with specific defensive capabilities. The proposed approach maximizes flexibility to develop and test an integrated system while allowing initial capabilities to be fielded.

- **Weapons**. Weapons consisting of interceptors and high energy lasers (HELs) would be used to negate threat missiles. Interceptors would use either direct impact or directed fragmentation technology. BMDS weapons are designed to intercept threat ballistic missiles in one or more phases of flight and could be activated from land, sea-, air-, or space-based platforms.

- **Sensors**. BMDS sensors provide the relevant incoming data for threat ballistic missiles. They acquire, record, and process data on threat missiles and interceptor missiles; detect and track threat missiles; direct interceptor missiles or other defenses (e.g., lasers); and assess whether a threat missile has been destroyed. These sensors include signal-processing subcomponents, which receive raw data and use hardware and software to process these data to determine the threat missile's location, direction,

velocity, and altitude. The data from these sensors would travel through the communication systems of the proposed BMDS to Command and Control (C2) where a decision would be made to employ a defensive weapon such as launching an interceptor. The technologies used by existing and proposed BMDS sensors are based on the frequency or electromagnetic (EM) energy spectrum used by the sensor and include radar, infrared, optical, and laser systems.

- **C2BMC**. C2BMC would effectively integrate all components of the BMDS and would consist of electronic equipment and software that enable military commanders to receive and process information, make decisions, and communicate those decisions regarding the engagement of threat missiles. Specifically, C2BMC would receive, fuse, and display tracking and status data from multiple components so that commanders at various locations would have the same integrated operating picture and could make coordinated decisions about deploying weapons. The BMDS C2BMC includes three primary parts, C2, Battle Management (BM), and Communications. C2 would provide an integrated architecture to plan, direct, control, and monitor BMDS activities. BM would control the launching or firing of missiles and integrate the surveillance, detect/track/classify, engage, and assess across the layered defenses. Communications would allow all BMDS components to exchange data and network with BMDS assets.

- **Support Assets**. Support assets would be used to facilitate BMDS development, testing, and deployment. Support assets include support equipment, infrastructure, and test assets. Support equipment includes general transportation and portable equipment (e.g., automotive, ships, aircraft, rail, generators); BMDS Test Bed equipment (e.g., aircraft, vehicles, ships, mobile launch platforms, operator control units, sensor operations equipment [antennas, electronic equipment, cooling units, prime power units]); and weapons basing platforms (e.g., Aegis Cruiser and Airborne Laser [ABL] aircraft). Infrastructure includes docks, shipyards, launch facilities, and airports/air stations. Test assets include test range facilities, targets (missiles and drones), countermeasure devices, simulants, test sensors, optical and infrared cameras, computers, and observation vehicles. These test assets would simulate a threat missile in a realistic environment and assess and provide data used to enhance the performance of BMDS components in negating those threats. Some of the equipment (i.e., radar and tracking stations) and infrastructure (e.g., launch facilities) and all of the test assets comprise the BMDS Test Bed.

Acquisition Life Cycle Phases

The MDA, as the acquisition agency for the BMDS, has implemented a new, more flexible approach to its development. This approach is capability driven and component-based. Capability-based planning allows MDA to develop capabilities and system performance objectives based on technology feasibility, engineering analyses, and the

potential capability of the threat. Spiral development is an iterative process for developing the BMDS by refining program objectives as technology becomes available through research and testing with continuous feedback among MDA, the test community, and the military operators. Thus, MDA can consider deployment of a missile defense system that has no specified final architecture and no set of operational requirements but which will be improved incrementally over time. Development, testing, and deployment of an integrated BMDS would occur over several years using this evolutionary, spiral development process. Each new technology would go through development; promising technologies would go through testing and demonstration; and proven technologies would be incorporated into the BMDS.

- **Development**. Development includes the various activities that would support research and development of the BMDS components and overall systems. This would include planning, budgeting, research and development, systems engineering, site preparation and construction, repair, maintenance and sustainment, manufacture of test articles and initial testing, including modeling, simulation, and tabletop exercises.

- **Testing**. Testing of the BMDS involves demonstration of BMDS elements and components through test and evaluation. The successful demonstration of the BMDS would rely on a robust testing program aimed at producing credible system characterization, verification, and assessment data. To confirm these capabilities, MDA would continue to develop Test Beds using existing and new land-, sea-, air-, and space-based assets. Some construction at various geographic locations would be required to support infrastructure and assets where BMDS components and the overall system would be tested. Testing of the BMDS includes ongoing and planned tests (e.g., ground tests [GTs], flight tests) of components that might be incorporated into the BMDS, as well as tests of the layered, integrated BMDS through increasingly realistic System Integration Tests through 2010 and beyond.

- **Deployment**. Deployment of the BMDS refers to the fielding (including the manufacture, site preparation, construction and transport of systems) and sustainment (including operations and maintenance, training, upgrades, and service life extension) of BMDS architecture. The evolving BMDS is intended to have the capability over time to deploy different combinations of interoperable components. Deployment also would involve the transfer of facilities, elements and programs to the military services. On December 17, 2002, President Bush directed the fielding of initial defensive operation (IDO) capabilities by 2004, which would provide limited protection to defend the U.S. against ballistic missile attack. In October 2004, MDA achieved a limited missile defense capability (LDC) when certain BMDS components could also be placed on alert and used in defensive operations.

- **Decommissioning**. Decommissioning would involve the demilitarization and final removal and disposal of the BMDS components and assets. Plans would be made for

decommissioning BMDS components by either demolition or transfer to other uses or owners.

Alternatives

In this PEIS, MDA considers two alternatives to implementing an integrated BMDS that address the use of weapons components from land-, sea-, air-, and space-based platforms in addition to the No Action alternative as required by NEPA.

- **Alternative 1**. Under Alternative 1, the MDA would develop, test, deploy, and plan to decommission land-, sea-, and air-based platforms for BMDS weapons components and related architecture and assets. Alternative 1 would include space-based sensors, but would not include space-based defensive weapons.

- **Alternative 2.** Under Alternative 2, the MDA would develop, test, deploy, and plan to decommission land-, sea-, air-, and space-based platforms for BMDS weapons components and related architecture and assets. Alternative 2 would be identical to Alternative 1, with the addition of space-based defensive weapons.

- **No Action Alternative**. Under No Action the MDA would not develop, test, deploy, or plan for decommissioning activities for an integrated BMDS. Instead, the MDA would continue existing development and testing of discrete systems as stand-alone missile defense capabilities. Individual systems would continue to be tested but would not be subjected to System Integration Tests.

Affected Environment

To assess the impacts of implementing the proposed BMDS, it is necessary to characterize the existing condition of the affected environment in the locations where various BMDS implementation activities are proposed to occur. The affected environment includes all land, air, water, and space environments where proposed activities are reasonably foreseeable. For this PEIS, the affected environment includes all existing locations for ranges, installations, and facilities that the MDA has used, uses, or proposes to use for the BMDS both in the U.S. and outside the continental U.S. MDA determined that activities associated with the proposed BMDS might occur in locations around the world. Therefore, the affected environment has been considered in terms of global biomes, broad ocean areas, and the atmosphere.

Each biome covers a broad region, both geographically and ecologically for both domestic and international locations where components of the proposed BMDS may be located or operated. Climate, geography, geology, and distribution of vegetation and wildlife determine the distribution of the biomes. Using biomes as affected environment designations enables future site-specific environmental documentation to tier from this

PEIS. Note that there are no reasonably foreseeable BMDS activities that would occur in Antarctica; therefore, it is not included among the terrestrial biomes.

The affected environment has been divided into nine terrestrial biomes, the Broad Ocean Area (BOA), and the Atmosphere. Exhibit ES-3 describes the affected environment, and Exhibit ES-4 illustrates the global distribution of the biomes.

Exhibit ES-3. Affected Environment Descriptions[1]

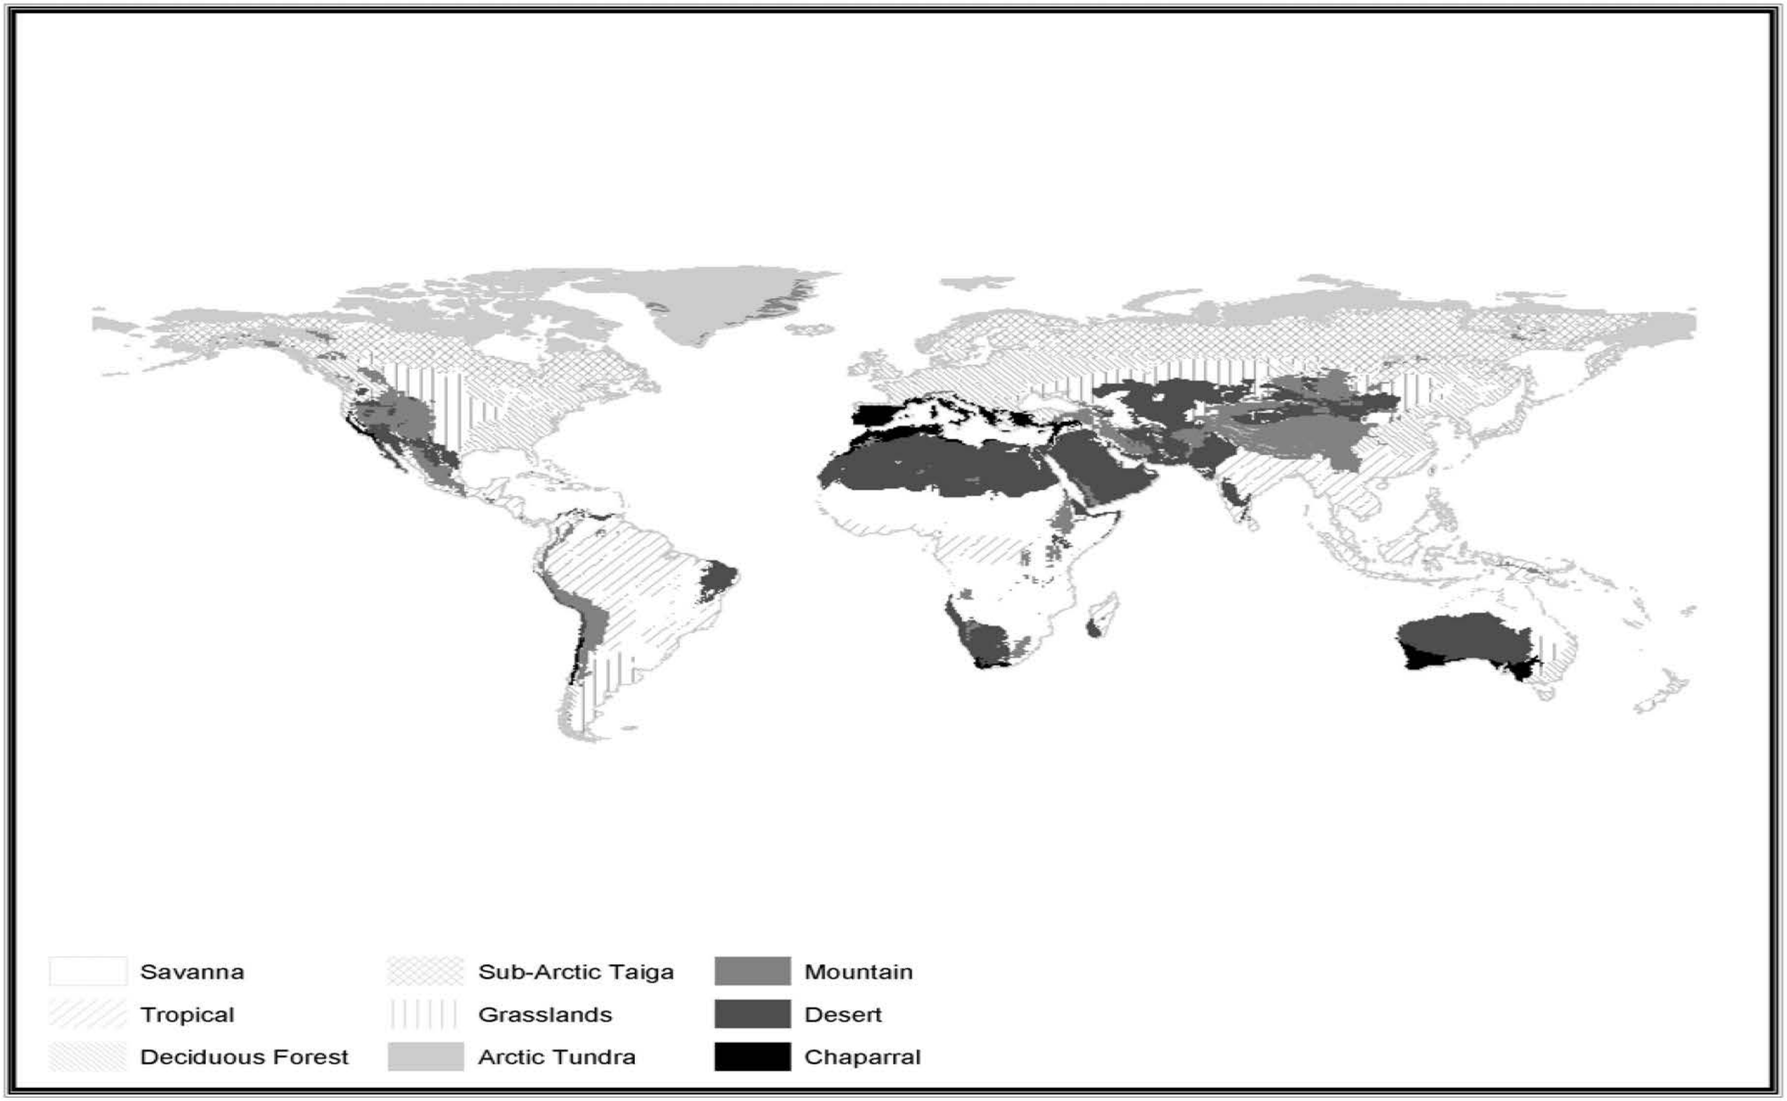
Description	Latitudinal Location	Areas of Interest for the BMDS
Arctic Tundra Biome	Areas above 60° North	Arctic regions of North America and the arctic coastal regions that border the North Atlantic Ocean, North Pacific Ocean, and Arctic Ocean, including parts of Alaska, Canada, and Greenland
Sub-Arctic Taiga Biome	Between 50° and 60° North	Sub-arctic regions of North America and sub-arctic coastal regions that border the North Pacific Ocean, including portions of Alaska
Deciduous Forest Biome	Mid-latitudes, between the polar regions and tropical regions	Eastern and northwestern U.S. and portions of Europe
Chaparral Biome	Western coastal regions of continents between 30° and 40° both North and South of the equator	Portion of the California coast and coastal region of the Mediterranean from the Alps to the Sahara Desert and from the Atlantic Ocean to the Caspian Sea
Grasslands Biome	No particular latitudinal range; occurs in the interior of all continents, except Antarctica	Prairie regions of Midwestern U.S.
Desert Biome	Between 15° and 35° both North and South of the equator	Arid environment of southwestern U.S.

[1] The latitudinal designations identify the general location for each biome; however, the biomes do not have rigid edges that begin and end at these latitudes. Therefore, there may be some overlap of biomes at or near these latitudinal designations.

Exhibit ES-3. Affected Environment Descriptions[1]

Description	Latitudinal Location	Areas of Interest for the BMDS
Mountain Biome	No particular latitudinal range; applies to areas with high elevations just below and above the snow line of a mountain	Rocky Mountains in the western U.S. and Alps in Central Europe
Tropical Biome	Between 23.5° North (Tropic of Cancer) and 23.5° South (Tropic of Capricorn)	Pacific Equatorial Islands
Savanna Biome	Between 5° and 20° both North and South of the equator	Northern Australia
BOA	No particular latitudinal range	Pacific, Atlantic and Indian Oceans
Atmosphere	No particular latitudinal range; refers to the atmosphere that envelops the entire Earth	Four principal atmospheric layers: troposphere, stratosphere, mesosphere, and ionosphere (or thermosphere)

Exhibit ES-4. Map of Global Biomes



Source: Modified From National Geographic, 2003b

The characteristics (e.g., climate, soil types, flora and fauna) that define global biomes are the same regardless of whether the biome area of concern is coastal or inland. However, unique features (e.g., wetlands, estuaries, wind currents, hurricanes) of coastal biome areas may affect the environmental impacts. Therefore, the Affected Environment discusses these unique features within the biome descriptions. Describing coastal areas as part of the larger inland biomes minimizes repetition among the descriptions yet captures the important aspects of the coastal areas in a way suitable for impacts analysis. For this PEIS, the existing environmental conditions within each biome, as well as the BOA and the Atmosphere, were assessed based on several resource areas, as appropriate.

Resource Areas

The resource areas considered in this analysis are those resources that can potentially be affected by implementing the proposed BMDS. Some resource areas are site-specific or local in nature and therefore cannot be effectively analyzed in this type of programmatic document. The potential impacts on these resource areas are more appropriately discussed in subsequent site-specific documentation, tiered from this PEIS. The resource areas analyzed in this PEIS include: air quality, airspace, biological resources, geology and soils, hazardous materials and hazardous waste, health and safety, noise, transportation, and water resources. The MDA has included orbital debris as a resource consideration because of the likelihood of orbital debris occurring from various launch and test activities and its potential for impact to health and safety and the environment.

Other resource areas including cultural resources, environmental justice, land use, socioeconomics, utilities, and visual resources depend upon site-specific or local factors. Each of these was discussed regarding methodology and thresholds for significance to provide the reader with a “roadmap” for performing future site-specific analyses tiering from this PEIS. These discussions outline the types of information that would be needed to conduct site-specific analyses and identify the steps necessary to ensure that potential impacts are thoroughly and appropriately considered.

Environmental Consequences

To determine environmental consequences or impacts of implementing the proposed BMDS, its components (i.e., weapons, sensors, C2BMC, and support assets) were considered as they are developed, tested, deployed and decommissioned during these acquisition life cycle phases. Not all of the activities associated with the proposed BMDS are expected to produce environmental impacts. Only those activities with expected impacts for each life cycle phase are identified. Further, only those activities that are considered reasonably foreseeable are analyzed in this PEIS. BMDS programs that are largely conceptual are not analyzed in this document.

Because of the extensive nature of this project, this PEIS analyzes the BMDS as described in the following four steps.

Step 1 – Identify and Characterize Activities

The BMDS is organized by component (i.e., weapons; sensors; C2BMC; and support assets). Each component has life cycle phase activities associated with developing, testing, deploying, and decommissioning those components within the BMDS. These activities produce environmental impacts, which are examined in this PEIS. To consider impacts of the BMDS, the emissions/stressors from the component life cycle phases were identified and characterized.

Step 2 – Identify Activities with No Potential for Impact

Once the activities were identified, analysis revealed that some of those activities had no potential for (significant) impact. This conclusion was reached because either previous NEPA analysis revealed insignificant impacts, or because the activity was typically categorically excluded. These activities are not further analyzed in this PEIS.

Step 3 – Identify Similar Activities across Life Cycle Phases

The remaining activities with the potential for environmental impacts were then examined to determine which had similar environmental impacts. For example, impacts associated with site preparation and construction in the development phase would be the same as impacts from site preparation and construction activities in the testing and deployment phases of the life cycle. Accordingly many activities were addressed together to eliminate redundancy.

Step 4 – Conduct Environmental Analyses

The final step in the BMDS analysis is to determine the respective impact resulting from the proposed activities. The significance of an impact that an activity has on the environment is a function of the nature of the receiving environment. For example, a booster launch has different emissions than those resulting from activating a chemical laser. Whether those emissions create impacts and the degree of significance of these impacts depends, among other things, upon the environment in which they are released.

In this analysis, the PEIS considers the emissions/stressors from each component's activity in the context of each resource area (e.g., air quality, biological resources, water resources, etc.). Impacts were distinguished based on the different operating environments (land, sea, and air for Alternative 1 and land, sea, air, and space for Alternative 2) in which the activity would occur. These impacts were further distinguished based on the worldwide biomes in which the activity would occur.

As a result, the PEIS is organized by BMDS component, examining each resource area, and distinguishing between operating environments in the context of a particular biome. The analysis describes where the impacts differ based on the operating environment or biome.

Life Cycle Phase Activities

Development phase activities with the potential to produce environmental impacts include site preparation and construction and testing. Both of these activities occur in other life cycle phases for the proposed BMDS, and so the analysis has been combined where appropriate. For example, testing of component prototypes (development phase) has been assumed to cause the same or similar impacts as testing of component test articles (test phase), and so these activities were analyzed as one activity.

Test phase activities were considered in two distinct analyses: one focused on the components and their individual test activities, and the other focused on System Integration Testing which could include multiple components with one or more attempted intercepts to test system capability and effectiveness in increasingly robust and realistic test scenarios.

Component test activities assumed to have potential impacts on the environment were considered for each component as shown in Exhibit ES-5.

Exhibit ES-5. Component Test Activities with Potential Impacts

Component	Activity	Source of Impact	Impacts Analysis
Weapons-Laser	Manufacturing of Test Articles	Manufacturing/assembly of laser components and chemicals	Activity categorically excluded or previously analyzed and found to have no significant impact. Rationale presented in Section 4.1.1.10 Support Assets - Test Assets
	Site Preparation and Construction	Construction or modifications necessary to support laser use/firing	Section 4.1.1.9 Support Assets - Infrastructure

Exhibit ES-5. Component Test Activities with Potential Impacts

Component	Activity	Source of Impact	Impacts Analysis
	Transportation	Transport of the laser and chemicals to appropriate location	Activity categorically excluded or previously analyzed and found to have no significant impact. Rationale presented in Section 4.1.1.8 Support Assets - Support Equipment
	Activation	Firing the laser	Section 4.1.1.1 Weapons - Lasers
Weapons-Interceptor	Manufacturing of Test Articles	Manufacturing interceptor components and propellants	Activity categorically excluded or previously analyzed and found to have no significant impact. Rationale presented in Section 4.1.1.10 Support Assets - Test Assets
	Site Preparation and Construction	Construction or modifications necessary to support launch	Section 4.1.1.9 Support Assets - Infrastructure
	Transportation	Transport of the booster, kill vehicle, and propellants to the launch location	Activity categorically excluded or previously analyzed and found to have no significant impact. Rationale presented in Section 4.1.1.8 Support Assets - Equipment
	Prelaunch	Assembly and fueling of the booster or kill vehicle, as appropriate	Section 4.1.1.2 Weapons - Interceptors

Exhibit ES-5. Component Test Activities with Potential Impacts

Component	Activity	Source of Impact	Impacts Analysis
	Launch/Flight	Ignition of rocket motors and flight of boosters or separation of kill vehicle and subsequent flight along its trajectory	Section 4.1.1.2 Weapons - Interceptors
	Postlaunch	Clean up or debris recovery, if required	Section 4.1.1.2 Weapons - Interceptors
Sensors	Manufacturing	Manufacturing/assembly of the sensor hardware and software	Activity categorically excluded or previously analyzed and found to have no significant impact. Rationale presented in Section 4.1.1.10 Support Assets - Test Assets
	Site Preparation and Construction	Construction or modifications necessary to support sensor use	Section 4.1.1.9 Support Assets - Infrastructure
	Transportation	Transport of the sensor to appropriate location	Activity categorically excluded or previously analyzed and found to have no significant impact. Rationale presented in Section 4.1.1.8 Support Assets - Equipment
	Activation	Use of the sensor	Sections 4.1.1.3 Sensors - Radar, 4.1.1.4 Sensors - Infrared and Optical, and 4.1.1.5 Sensors - Laser

Exhibit ES-5. Component Test Activities with Potential Impacts

Component	Activity	Source of Impact	Impacts Analysis
C2BMC	Manufacturing	Assembly of associated hardware and software	Activity categorically excluded or previously analyzed and found to have no significant impact. Rationale presented in Section 4.1.1.10 Support Assets - Test Assets
	Site Preparation and Construction	Construction or modification for computer terminals, antennas, and underground cable trenching	Section 4.1.1.9 Support Assets - Infrastructure
	Transportation	Transport of C2BMC to appropriate location	Activity categorically excluded or previously analyzed and found to have no significant impact. Rationale presented in Section 4.1.1.8 Support Assets - Equipment
	Activation	Use of computer terminals, antennas, and underground cable	Sections 4.1.1.6 C2BMC - Computer Terminal and Antennas, 4.1.1.7 C2BMC - Underground Cable
Support Assets-Support Equipment	Manufacturing	New or major modification of existing support equipment	Activity categorically excluded or previously analyzed and found to have no significant impact. Rationale presented in Section 4.1.1.10 Support Assets - Test Assets

Exhibit ES-5. Component Test Activities with Potential Impacts

Component	Activity	Source of Impact	Impacts Analysis
	Operational Changes	Implementation of new operating parameters of existing support equipment	Section 4.1.1.8 Support Assets - Equipment
	Site Preparation and Construction	New construction or major modification of existing infrastructure	Section 4.1.1.9 Support Assets - Infrastructure
	Transportation	Transport of support equipment	Activity categorically excluded or previously analyzed and found to have no significant impact. Rationale presented in Section 4.1.1.8 Support Assets - Equipment
Support Assets-Infrastructure	Site Preparation and Construction	Construction or modification of infrastructure	Section 4.1.1.9 Support Assets - Infrastructure
Support Assets-Test Assets	Manufacturing	Assembly of hardware/software associated with the test sensor	Activity categorically excluded or previously analyzed and found to have no significant impact. Rationale presented in Section 4.1.1.10 Support Assets - Test Assets
	Site Preparation and Construction	Construction or modifications necessary to support the test sensor or launch	Section 4.1.1.9 Support Assets - Infrastructure

Exhibit ES-5. Component Test Activities with Potential Impacts

Component	Activity	Source of Impact	Impacts Analysis
	Transportation	Transport of the sensor, booster and propellants to the test location	Activity categorically excluded or previously analyzed and found to have no significant impact. Rationale presented in Section 4.1.1.8 Support Assets - Equipment
	Activation	Use of the test sensor in a test event	Section 4.1.1.3 Sensors - Radar, 4.1.1.4 Sensors - Infrared and Optical, and 4.1.1.5 Sensors - Laser
	Prelaunch	Assembly and fueling of the booster as appropriate	Section 4.1.1.2 Weapons - Interceptors
	Launch/Flight	Ignition of rocket motors, separation from launch platform, and flight of the boosters or separation of the target object and subsequent flight along its trajectory	Section 4.1.1.2 Weapons - Interceptors
	Use of Countermeasures, Simulants or Drones	Use and deployment of various countermeasures, simulants a or drones to support testing	Section 4.1.1.10 Support Assets - Test Assets
	Postlaunch	Clean up or debris recovery to include launch platform, countermeasures, and simulants, if required	Section 4.1.1.2 Weapons - Interceptors

System Integration Testing of the BMDS would occur at the system level. System Integration Tests evaluate the ability of various component configurations to work together. System Integration Testing would be used to assess the ability of BMDS

components to work interoperably to meet the required functional capabilities of the BMDS as a system and to demonstrate performance. System Integration Tests would integrate existing and planned components such as sensors, weapons, and C2BMC. This PEIS assesses the potential for environmental impacts of integrated BMDS testing under Alternatives 1 and 2. Test integration activities would involve land-, sea-, and air-based operating environments for weapons; and land-, sea-, air- and space-based operating environments for sensors, C2BMC, and support assets for Alternative 1. Assessment of Alternative 2 considers only the additional impacts of the proposed space-based operating environment for interceptors. System Integration Tests with the potential for environmental impacts are shown in Exhibit ES-6.

Exhibit ES-6. Description of System Integration Tests

Test	Activities
Integrated Ground Tests (GTs)	GTs are tests used to collect data for BMDS components characterization and assessment and do not include booster function flight tests. GTs aim to reproduce the existing state of BMDS architecture, typically components scheduled for upcoming flight tests, to prepare for those flight tests and to assess component performance. For the purposes of this PEIS GTs do not include activities associated with components but rather have been focused on System Integration Testing.
System Integration Flight Tests (SIFTs)	SIFTs are conducted to verify the integration of select BMDS components. These tests generally include a target launch, sensors tracking the target, laser activation or an interceptor launch, and sensors to determine whether the target was destroyed. The number of sensors, weapons, and targets used in a SIFT can be adjusted to create the desired test scenario.

The analysis of intercept impacts includes a discussion of the impact of debris from an intercept. Depending on the location used for testing or deployment of weapons, debris may impact either inland or in marine environments. Therefore, impacts from postlaunch activities involving intercepts are subcategorized based on where intercept debris would be likely to impact. For any single intercept, it was assumed that the debris impacts would occur within a single receiving environment, either on land or in water.

Not all test activities would have environmental impacts and MDA has determined that modeling, simulation and analysis; modeling defense integration exercises; and integrated missile defense wargames would not result in significant impacts. These are virtual tests (modeling and computational analysis) or software compatibility and communication tests that would be conducted within existing laboratory or test facilities.

Deployment activities with potential impacts on the environment would include production of the components, site preparation and construction, use of human services, transport of components to the deployment site, testing (prelaunch, launch/flight, activation, postlaunch) and maintenance or sustainment of the components. For purposes of this analysis, the environmental impacts associated with transportation are assumed to be the same as the impacts associated with transporting the components to a test location and the impacts associated with maintenance are assumed to be the same as or similar to the impacts associated with manufacturing activities.

Decommissioning activities would include demilitarization and disposal or replacement of the component, recycling and disposal of hazardous materials. The environmental impacts associated with decommissioning of specific components would be more appropriately addressed in subsequent tiered environmental analyses; however, this PEIS provides a roadmap for considering impacts of decommissioning for each component.

Impacts from accidents and spills are considered where appropriate in this analysis. Specifically, the impacts from booster failures and from spills or releases of laser chemicals, booster propellants, and fuels used to power support assets have been considered. Boosters can fail on or directly above the launch pad or at some point during flight. If a booster fails on or above the pad, there is a potential for damage to infrastructure at and around the launch area. The impact of this type of booster failure is most appropriately addressed in site-specific analysis. If a booster fails during flight, it may be possible to use a Flight Termination System (FTS), if there is one on the vehicle, to destroy the booster. In this instance, the resulting debris would be similar to that produced during an intercept. If an FTS is not used, the booster would fall substantially intact to the surface. The resulting impact from both in-flight failures would depend on the specific location and when in the flight the failure occurred. The quantity of residual propellant released may be greater under a booster failure then during a successful booster flight or intercept. Spills or releases of propellants and fuels would be handled in accordance with standard operating procedures at each facility, range or installation, and therefore, would not be expected to pose significant impacts to the environment.

Cumulative impacts of Alternative 1 and Alternative 2 have been considered in this PEIS. The CEQ NEPA regulations define cumulative impacts as those impacts on the environment that result from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions. (40 CFR 1508.7)

Summary of Environmental Impacts – Alternative

This alternative considers the use of land-, sea-, and air-based platforms for BMDS weapons components. Alternative 1 would include space-based sensors, but would not include space-based defensive weapons. A summary of potential environmental effects

from Alternative 1 is provided by subcomponent in Exhibits ES-7 through ES-10. The summary tables are organized by component and subcomponent. The analyses are specific to each resource area based on the impacts from the activities associated with the subcomponent. The impacts associated with the manufacturing, site preparation and construction, and transportation activities of components are discussed under Support Assets.

Exhibit ES-7. Summary of Environmental Impacts of Alternative 1 - Weapons

Resource Area	Lasers	Interceptors
Air Quality	Emissions from laser operation (less than 30 seconds) would be minimal and would be dispersed by wind and would not significantly affect local or regional air quality.	Negligible amounts of fuel and oxidizer vapors might be released during propellant transfers. Most launch emissions would be dispersed by wind and would not significantly affect local or regional air quality or ozone depletion.
Airspace	Following required scheduling and coordination procedures would minimize the potential for adverse impacts to airspace.	Following required scheduling and coordination procedures would minimize potential for adverse impacts to airspace.
Biological Resources	Emissions, noise, and the laser beam from laser activation could negatively impact biological resources. Emitted chlorine might damage vegetation; hydrogen chloride (HCl) might irritate birds flying through the exhaust cloud or reach and disrupt aquatic ecosystems. Wildlife could be startled by noise from laser support equipment. The laser beam could pose fire hazards to vegetation and eye and skin hazards to wildlife. However, impacts to these resources would be minimal if the beam is contained or directed upward.	The presence of launch-related personnel prior to launch, launch noise, and launch emissions could impact biological resources during launch; however, launches are relatively infrequent and would not be expected to significantly impact wildlife. Debris impacting water has the potential to cause non-acoustic effects to biological resources from physical impact from falling debris, entanglement in debris, and contact with or ingestion of debris or propellants. However, these effects would not significantly impact biological resources.
Geology and Soils	Soil acidity might be affected as a result of chlorine emissions from laser activation. Magnitude of impact would be related to the amount of limestone in the soils. However, chlorine emissions are small and laser activation relatively infrequent and the impacts to geology and soils would not be significant.	Potential impacts would not be significant. Launch emissions that occur above the mixing height or above the troposphere would not cause impacts. Soil acidity might be affected as a result of HCl emissions from some launch activities. Magnitude of impact would be related to the amount of limestone in the soils. Debris from boosters and kill vehicles could hit and affect the surface and soils where they impact, but there would be no significant impact on geology.
Hazardous Materials and Hazardous Waste	Spent laser chemicals and wastewater would be treated and disposed in accordance with applicable transport and management regulations to prevent impacts. Therefore, no significant impacts from hazardous materials or hazardous waste would be expected.	Applicable regulations and operating procedures would be followed and would prevent impacts from improper transport, management, or disposal of hazardous materials or hazardous waste.
Health and Safety	Following spill prevention and control procedures would reduce potential health and safety impacts from accidental releases of laser chemicals. Hazard distances would be established to protect against skin or eye hazards from the laser beam and inhalation hazards from air emissions; therefore, no significant health and safety impacts would be expected.	Potential health and safety impacts include exposure to explosives, contact with launch debris, and exposure to launch noise. Launches would take place on facilities with restricted access, preventing exposure of the public to these hazards. Following appropriate procedures during fueling and prelaunch operations would reduce potential impacts. On-site personnel would be protected from launch event hazards; therefore, no significant health and safety impacts would be expected.

Exhibit ES-7. Summary of Environmental Impacts of Alternative 1 - Weapons

Resource Area	Lasers	Interceptors
Noise	The public would be excluded from areas where noise from operational equipment would be detrimental and workers would use recommended hearing protection. Therefore, no significant noise impacts would be expected.	The launch and flight of boosters would produce launch noise and sonic booms. The public would not be in proximity to launch sites and therefore would not be exposed to significant noise levels. Launch personnel would either leave the area or wear recommended hearing protection. Therefore, no significant noise impacts would be expected.
Transportation	Air traffic might be impacted by laser activation. Following required scheduling and coordination procedures would minimize the potential for adverse impacts. No significant impacts would be expected to other transportation modes.	Impacts on traffic due to temporary road closures are not expected to be significant. Notices to Airmen (NOTAMs) and Notices to Mariner (NOTMARs) would provide sufficient warning to prevent significant impacts to air and marine transportation.
Water Resources	Some emissions from laser activation have the potential to temporarily and locally increase the acidity of surface waters. However, these emissions would be diluted and dispersed by receiving waters. Therefore, no significant water resource impacts would be expected.	Following appropriate procedures during fueling operations would reduce the potential for propellants to impact water resources. Some emissions from launches could temporarily and locally increase acidity of surface waters. However, these emissions would be diluted and dispersed by receiving waters and would not be expected to pose significant impacts to water resources.
Orbital Debris	N/A	Debris created from a booster failure while operating in the exoatmosphere would reenter Earth's atmosphere within a few months. Because the debris would be on orbit for a relatively short time it would not have a significant impact on orbiting structures. In addition, only a small amount of debris would survive reentry and therefore no significant impacts are expected.

Exhibit ES-8. Summary of Environmental Impacts of Alternative 1 - Sensors

Resource Area	Radars	Infrared and Optical Sensors	Laser Sensors
Air Quality	Emissions from radars would be limited to generator exhaust, which are considered in Support Assets.	Emissions from infrared and optical sensors would be limited to generator exhaust, which are considered in Support Assets.	Gas laser sensors would use inert gases, e.g., helium, nitrogen (N_2), and carbon dioxide (CO_2), which can be asphyxiants. Leaks of these gases would be insignificant relative to ambient oxygen levels; therefore no significant air quality impacts would be expected.
Airspace	NOTAMs would be issued and pilots would be restricted from electromagnetic radiation (EMR) hazard areas during radar activation. Restrictions would be short term and would not significantly impact airspace.	Activation of infrared and optical sensors would not interfere with airspace; therefore, no impacts to airspace would be expected.	Ground testing of laser sensors would be conducted in an established controlled firing area. Activation of laser sensors from air platforms would occur at an upward angle above commercial aircraft traffic. Therefore, no significant airspace impacts would be expected.
Biological Resources	There may be some risk of thermal heating to birds from the COBRA DANE radar as discussed in Appendix N, Impacts of Radar on Wildlife. However, MDA has proposed mitigation measures such as limiting the use of the radar during migratory seasons and when flocks may be in the vicinity. Therefore, no significant biological resource impacts would be expected.	Activation of infrared and optical sensors would not interfere with biological resources; therefore, no significant biological resource impacts would be expected.	Birds and mammals in the laser beam path could suffer eye damage. The short duration of laser activation and small range area would minimize impacts. Direction of laser sensor beams from space platforms towards the Earth's surface, would suffer distortion from atmospheric conditions reducing the radiance level of the lasers. Therefore, no significant impacts to biological resources would be expected.
Geology and Soils	Impacts would be limited to accidental spills of diesel fuel or coolants from support generators, which are considered in Support Assets.	Impacts would be limited to accidental spills of diesel fuel or coolants from support generators, which are considered in Support Assets.	Activation of laser sensors would not impact geology and soils.
Hazardous Materials and Hazardous Waste	Applicable regulations and procedures would be followed and would minimize impacts from management of hazardous materials or waste.	Applicable regulations and procedures would be followed and would minimize impacts from management of hazardous materials or waste.	Refrigerant 404, an ozone-depleting substance, may be used to cool some laser sensors. These would be closed loop systems, with replacement of refrigerant only during routine maintenance performed according to applicable regulations, therefore, no significant impacts from hazardous materials or waste management would be expected.

Exhibit ES-8. Summary of Environmental Impacts of Alternative 1 - Sensors

Resource Area	Radars	Infrared and Optical Sensors	Laser Sensors
Health and Safety	Prior to activation of radars, an EMR survey would be conducted to consider hazards to personnel, fuels, and ordnance. Resulting recommendations would establish safety exclusion zones to minimize exposures. Safety exclusion zones would also be established to minimize high voltage exposure from generator wiring and cabling. Therefore, no significant health and safety impacts would be expected.	Activation of infrared and optical sensors would not impact health and safety. Safety exclusion zones would be established as required to minimize high voltage exposure from generator wiring and cabling.	Sensor laser beams can be hazardous to the eyes of living organisms within a certain hazard distance. Applicable regulations and procedures, such as establishing restricted areas, displaying warning signs, designating restricted areas, and removing reflective surfaces, would reduce potential health and safety impacts below significant levels. Safety exclusion zones would also be established to minimize high voltage exposure from generator wiring and cabling.
Noise	Noise impacts would be limited to noise produced by generators, which are considered in Support Assets.	Noise impacts would be limited to noise produced by generators, which are considered in Support Assets.	Noise impacts would be limited to noise produced by generators, which are considered in Support Assets.
Transportation	NOTAMs and NOTMARs would provide sufficient warning. Therefore, no significant transportation impacts would be expected.	Activation of infrared and optical sensors would not interfere with transportation. Therefore, no significant transportation impacts would be expected.	Activation of laser sensors would not interfere with transportation. Therefore, no significant transportation impacts would be expected.
Water Resources	Releases of diesel fuel or coolants from support generators into surface water would be diluted rapidly; therefore, no significant impacts to water resources would be expected.	Releases of diesel fuel or coolants from support generators into surface water would be diluted rapidly; therefore, no significant impacts to water resources would be expected.	Liquids used in laser sensor cooling systems are non-hazardous and in the unlikely event of a release would not be expected to impact water resources.
Orbital Debris	Space-based radars could reenter the Earth's atmosphere due to failure; however, most objects break up and vaporize in the upper atmosphere under intense forces and heating during reentry. Even if an object survives reentry, it would most likely land in an ocean area, and the chance of hitting populated land area would be small. Therefore, no significant orbital debris impacts would be expected.	Space-based infrared and optical sensors could reenter the Earth's atmosphere due to failure; however, most objects break up and vaporize in the upper atmosphere under intense forces and heating during reentry. Therefore, no significant orbital debris impacts would be expected.

Exhibit ES-9. Summary of Environmental Impacts of Alternative 1 - C2BMC

Resource Area	Computer Terminals and Antennas	Underground Cable
Air Quality	Activation emissions would be limited to generator exhaust. Impacts from generator emissions are considered in Support Assets.	Impacts would be limited to ground disturbances resulting from construction activities. Impacts from ground disturbance are considered in Support Assets.
Airspace	Radio transmission frequencies used by computer terminals and antennas could impact airspace through interference with commercial air traffic control communications. Radio frequency use and testing would be coordinated with the appropriate air traffic control agencies; therefore, no significant airspace impacts would be expected.	Activation of underground cable would not interfere with airspace; therefore, no significant airspace impacts would be expected.
Biological Resources	Biological resources could be impacted by activation activities, but the level of impact would vary based on signal frequency and energy, and the proximity of the source to sensitive environments or specific threatened or endangered species. Radio frequency use and testing would be coordinated with the appropriate resource management agencies; therefore, no significant biological resource impacts would be expected.	Activation of underground cable would not interfere with biological resources. Therefore, no significant biological resource impacts would be expected.
Geology and Soils	Activation of computer terminals and antennas would not interfere with geology and soils. Therefore, no significant geology and soils impacts would be expected.	Impacts to geology and soils would be limited to site preparation activities. Impacts from ground disturbance are considered in Support Assets.
Hazardous Materials and Hazardous Waste	Any hazardous materials or wastes used or generated would be handled in accordance with appropriate regulations. Therefore, no significant hazardous materials and hazardous waste impacts would be expected.	Impacts from hazardous materials and hazardous wastes would be limited to site preparation activities. Impacts from ground disturbance are considered in Support Assets.
Health and Safety	Health and safety impacts would vary based on signal frequency and energy, and the proximity of the source to site personnel or the public. No significant health and safety impacts would be expected.	Potential health and safety hazards would be limited to dust/particulate inhalation, improper chemical handling, and improper use of machinery during site preparation and construction. Impacts from ground disturbance are discussed in Support Assets.
Noise	Noise impacts associated with activation of computer terminals and antennas would be limited to noise produced by generators. Impacts related to generator noise are discussed in Support Assets.	The activation of underground cable would not produce noise that has the potential to impact sensitive receptors.
Transportation	Personnel operating and maintaining computer terminals and antennas would generate traffic as a result of activation. Personnel would be on site only during operating hours and during routine maintenance activities; therefore, no significant transportation impacts would be expected.	Any necessary repairs to underground cable would require excavation of the cable. These activities could result in impacts to transportation through movement of equipment and personnel to the repair site. However, this would occur infrequently, therefore, impacts to transportation would not be significant.

Exhibit ES-9. Summary of Environmental Impacts of Alternative 1 - C2BMC

Resource Area	Computer Terminals and Antennas	Underground Cable
Water Resources	Activation of computer terminals and antennas would not interfere with water resources. Therefore, no significant impacts would be expected.	Impacts to water resources might result from site preparation activities. Impacts from ground disturbance are considered in Support Assets.
Orbital Debris	Space-based computer equipment could reenter the Earth's atmosphere due to failure, but no significant orbital debris impacts would be expected.	N/A

Exhibit ES-10. Summary of Environmental Impacts of Alternative 1 – Support Assets

Resource Area	Support Equipment	Infrastructure	Test Assets
Air Quality	Increased use of support equipment resulting in greater quantities of emissions could impact air quality. The significance of the impact depends on the local and regional regulatory setting and the physical climate where emissions would occur.	Site preparation and construction activities would result in air emissions; however, it is assumed that the impact on air quality would be temporary and localized. Therefore, no significant air quality impacts would be expected.	The development and use of targets, simulants, countermeasures, and drones could impact air quality. Following standard operating procedures would reduce potential impacts to air quality below significant levels.
Airspace	Operational use changes of support assets would not interfere with airspace. Increases in support asset operations would be in accordance with existing airspace use regulations. Therefore, no significant airspace impacts would be expected.	Site preparation and construction would not interfere with airspace. Therefore, no significant airspace impacts would be expected.	Simulants, countermeasures, and their delivery systems (boosters) could impact airspace. Site-specific analyses would be conducted to address these potential impacts.
Biological Resources	Following required scheduling, duration of testing, and completing required agency regulatory agency consultations would reduce potential impacts on biological resources below significant levels.	Site preparation and construction activities could impact biological resources. Site-specific analyses and regulatory agency consultations would be conducted to address these potential impacts.	Potential impacts on biological resources could be associated with debris in which simulants and countermeasures were used. Site-specific analysis would be conducted to address these potential impacts.
Geology and Soils	In general, operational use changes would not be expected to significantly impact geology and soils. Mitigation measures may be used in instances where impacts could occur to reduce impacts to less than significant levels.	Construction would incorporate design parameters consistent with the geologic setting to reduce potential seismic impacts. Construction activities could impact soils; however, Best Management Practices would be implemented to minimize impacts.	Development and use of simulants and countermeasures could impact soils based on the composition of the simulant or countermeasure. Site-specific analyses would be conducted to address potential impacts.
Hazardous Materials and Hazardous Waste	Hazardous waste would be handled and disposed in accordance with appropriate regulations. Therefore, no significant hazardous materials and hazardous waste impacts would be expected.	Hazardous waste would be handled and disposed in accordance with appropriate regulations. Therefore, no significant hazardous materials and hazardous waste impacts would be expected.	Hazardous waste would be handled and disposed in accordance with appropriate regulations. Therefore, no significant hazardous materials and hazardous waste impacts would be expected.
Health and Safety	Standard operating procedures specific to an action or installation would be used and equipment training performed to reduce potential impacts to health and safety.	Standard operating procedures specific to an action or installation would be used and equipment training performed to reduce potential impacts to health and safety.	Standard operating procedures specific to an action or installation would be used and equipment training performed to reduce potential impacts to health and safety.

Exhibit ES-10. Summary of Environmental Impacts of Alternative 1 – Support Assets

Resource Area	Support Equipment	Infrastructure	Test Assets
	Therefore, no significant health and safety impacts would be expected.	Therefore, no significant health and safety impacts would be expected.	Therefore, no significant health and safety impacts would be expected.
Noise	Noise impacts are based on site-specific receptors and are regulated on a regional basis. Site-specific analysis would be conducted for actions that may have noise impacts.	Noise impacts are based on site-specific receptors and are regulated on a regional basis. Site-specific analysis would be conducted for actions that may have noise impacts.	The development and use of simulants or countermeasures would not have noise impacts. The launch and flight of targets would produce noise similar to that of interceptors. However, as described in Exhibit ES-6 no significant noise impacts would be expected.
Transportation	Operational use changes that increase the amount of time that support equipment are used could impact transportation. However, these impacts are not expected to be significant.	Site preparation and construction activities may require the use of heavy machinery and an influx of construction workers which could change the congestion and level of demand for access to the existing roadways. However, these activities would not be expected to cause a significant impact on transportation.	The development and the use of simulants would not impact transportation. Short-term road closures, the issuance of NOTAMs and NOTMARs to notify pilots and mariners of area closures, and debris recovery activities would not be expected to impact transportation.
Water Resources	Operational use changes occurring at existing facilities designed for the support equipment would not impact water resources. Operational use changes that result in impacts to areas not specifically designed for use of the support equipment could be subject to additional environmental review.	Applicable protocols and permits would reduce potential impacts to water resources from construction activities to below significant levels. Site-specific analyses would be conducted for new installations.	The development and use of simulants and countermeasures could impact water resources. Site-specific analyses would be conducted to determine and address impacts.
Orbital Debris	No impacts from orbital debris would occur as a result of the development of new or the major modification of existing equipment or an operational use change of such equipment. Space-based equipment (satellites) could reenter the Earth's atmosphere due to failure, but would not likely result in significant impacts because they would burn up on reentry.	No impacts from orbital debris would occur as a result of the development of new or the major modification of existing infrastructure.	If countermeasures are used and remain on-orbit, they have the potential to disrupt or damage space-based assets (e.g., communication satellites). However, because the debris would be on orbit for a relatively short time it would not have a significant impact on orbiting structures. In addition, only a small amount of debris would survive reentry and therefore no significant impacts are expected.

Test Integration

System Integration Tests would integrate existing and planned components such as sensors, weapons, and C2BMC. Under Alternative 1, test integration activities would involve land-, sea-, and air-based platforms for weapons; and land-, sea-, air- and space-based platforms for sensors, C2BMC, and support assets. Integrated GTs and SIFTs have the potential for environmental impacts, as described in Exhibit ES-6.

For this PEIS, two representative scenarios that could be used during SIFTs were considered for Alternative 1. These two representative scenarios involve similar activities (launches of targets, use of multiple sensors, and use of land-, sea-, and air-based weapons); however, they differ in number of target launches and number of weapons used. Both representative scenarios may be used to support the proposed BMDS and are analyzed in this PEIS. The activities associated with each type of System Integration Tests that were analyzed in this PEIS include

- **Integrated GTs**. The activation of multiple sensors and C2BMC components, and passive activation of weapons (e.g., powering the tracking and communication aspects of the weapons system but not firing the weapon) within the same biome or across several biomes, which would coordinate the control and transfer of information between land-, sea-, and air-based weapons.

- **SIFT Scenario 1- Single Weapon with Intercept**. The activation of multiple sensors and C2BMC components within the same biome or across several biomes coupled with the launch of one target and the activation of a laser or launch of an interceptor, and the debris from an intercept.

- **SIFT Scenario 2- Multiple Weapons with Multiple Intercepts**. The activation of multiple sensors and C2BMC components within the same biome or across several biomes coupled with the launch of up to two targets from the same biome or different biomes, the activation or launch of multiple weapons in the same biome or multiple biomes, and the debris from intercepts.

A summary of potential environmental effects associated with Test Integration for Alternative 1 is provided in Exhibit ES-11. The analyses are specific to each resource area based on the impacts from the activities associated with each test.

Exhibit ES-11. Summary of Environmental Impacts of Alternative 1 - Test Integration

Resource Area	GT	SIFT Scenario 1	SIFT Scenario 2
Air Quality	Emissions from generators used to power sensors and C2BMC would be a small fraction of the *de minimis* threshold and would not impact air quality. The activation of radars, infrared, and optical sensors would not impact air quality.	Emissions from launch activities and laser activation would be less than two percent of *de minimis* thresholds; impacts to air quality would be insignificant.	Impacts to air quality would be insignificant, provided the activity is within parameters of the launch facility or range.
Airspace	Coordination with the FAA Air Route Traffic Control Center (ARTCC), military installations, and foreign countries with jurisdiction over affected airspace would minimize the potential for impact. All laser sensors would be operated using appropriate range safety regulations.	Close coordination with the FAA ARTCC, military installations, and foreign countries with jurisdiction for airspace management would minimize the potential for adverse impacts on airspace use and scheduling. Upon completion of such coordination for each test, there would be no significant impacts to airspace.	Close coordination with the FAA ARTCC, military installations, and foreign countries with jurisdiction over affected airspace would reduce the potential impacts to airspace. Upon completion of such coordination for each test, there would be no significant impacts to airspace.
Biological Resources	Potential impacts to the environment and the threatened and endangered species, the unique or sensitive environments, and the migratory, breeding, and feeding activities would be evaluated in site-specific analyses.	Potential impacts to the environment and the threatened and endangered species, the unique or sensitive environments, and the migratory, breeding, and feeding activities would be evaluated in site-specific analyses.	Potential impacts to the environment and the threatened and endangered species, the unique or sensitive environments, and the migratory, breeding, and feeding activities would be evaluated in site-specific analyses.
Geology and Soils	Fuel spills associated with generators would be controlled and cleaned up according to appropriate procedures; therefore any impacts would be insignificant.	HCl and particulate emissions from interceptor and target launches would not result in significant impacts to geology and soils.	HCl and particulate emissions from interceptor and target launches would not result in significant impacts to geology and soils.
Hazardous Materials and Hazardous Waste	Hazardous materials and waste would be handled according to all applicable regulations, and each test location would have a Spill Prevention, Control and Countermeasure (SPCC) plan in place to handle any spills or leaks of hazardous materials; therefore impacts would be insignificant.	Applicable regulations and procedures would be followed and would prevent impacts from management and disposal of hazardous materials or waste associated with laser activation and target and weapons launches.	Applicable regulations and procedures would be followed and would prevent impacts from management and disposal of hazardous materials or waste associated with laser activation and target and weapons launches.
Health and Safety	All safety procedures would be followed, safety zones would be established, and participating personnel would be trained	All safety procedures would be followed, safety zones would be established, and participating personnel would be trained and certified to reduce the potential for impacts to	All safety procedures would be followed, safety zones would be established, and participating personnel would be trained and certified to reduce the potential for impacts to

Exhibit ES-11. Summary of Environmental Impacts of Alternative 1 - Test Integration

Resource Area	GT	SIFT Scenario 1	SIFT Scenario 2
	and certified to reduce the potential for impacts to health and safety.	health and safety associated with launches of targets and weapons.	health and safety associated with launches of targets and weapons. The increased exposure to health and safety risks associated with SIFT Scenario 2 would not be expected to result in a significant impact.
Noise	Generators would be operated during tests, and sea- and air-based systems typically would not be operated in proximity to sensitive receptors. In general, the increase in noise from multiple generator use within an environment would not be significant.	Noise from launches of targets and weapons and sonic booms would occur in areas away from sensitive receptors, and would not result in significant impacts.	Noise from launches of targets and weapons and sonic booms would occur in areas away from sensitive receptors, and would not result in significant impacts.
Transportation	NOTAMs and NOTMARs would be issued in advance of testing events to allow aircraft and vessels to plan alternate routes to avoid the EMR hazard areas; the impacts would be insignificant.	Closures of roads, airspace, and marine areas would be of short duration and would be considered routine occurrences for launch sites, and issuance of NOTAMs and NOTMARs would allow vehicles to clear the affected areas. Impacts to transportation would be insignificant.	The increase in transportation requirements or any increases in the frequency, duration, or number of transport route closures would not result in a significant transportation impact.
Water Resources	In general, an increase in risk from hazardous materials and hazardous waste spills and an increase in demand for potable water would not result in significant impacts.	Impacts from the deposition of emissions, propellants, and debris into water resources would be dependent on the specific biome and the unique and sensitive water resources that occur in the biome. In general, impacts to water resources from laser activation and launches would not have additive impacts for activities occurring within the same biome.	Site-specific environmental analysis would be completed to evaluate potentially significant impacts. In general, impacts to water resources from laser activation and launches would not have additive impacts for activities occurring within the same biome.

Exhibit ES-11. Summary of Environmental Impacts of Alternative 1 - Test Integration

Resource Area	GT	SIFT Scenario 1	SIFT Scenario 2
Orbital Debris	N/A	Debris created from exoatmospheric intercepts would reenter Earth's atmosphere within a few months. Because the debris would be on orbit for a relatively short time it would not have a significant impact on orbiting structures. In addition, only a small amount of debris would survive reentry and therefore no significant impacts are expected.	Debris created from exoatmospheric intercepts would reenter Earth's atmosphere within a few months. Because the debris would be on orbit for a relatively short time it would not have a significant impact on orbiting structures. In addition, only a small amount of debris would survive reentry and therefore no significant impacts are expected.

Cumulative Impacts

The implementation of the proposed BMDS under Alternative 1 is worldwide in scope and potential application, and only other actions that are international in scope, have been considered for cumulative impacts. Regional or local past, present, or future actions, which may result in cumulative impacts, would be considered during the completion of site-specific NEPA analyses. Worldwide launch programs for commercial and government programs were determined to be actions of international scope that might be reasonably considered for cumulative impacts in this PEIS. Launches contribute to cumulative impacts in areas including ozone depletion, global warming, and orbital debris.

The cumulative impact on stratospheric ozone depletion from BMDS launches would be far less than and indistinguishable from the effects caused by other natural and man-made sources. The estimated emission loads of chlorine from both BMDS and worldwide launches from 2004 to 2014 would account for only 0.5 percent of the industrial chlorine load from the U.S. over the same 10-year period. Therefore, the cumulative impacts to ozone depletion would not be significant.

The cumulative impact on global warming from BMDS launches from 2004 to 2014 would be insignificant compared to other industrial sources (e.g., energy generation using fossil fuel) and activities (e.g., deforestation and land clearing). The BMDS launch emissions load of carbon monoxide (CO) and CO_2 to the troposphere and stratosphere would be only five percent of the emissions load from worldwide launches. However, even when accounting for both BMDS launches and worldwide launches over the 10-year period, the CO and CO_2 load is extremely small compared to emissions loads from other industrial sources, accounting for 3.5×10^{-4} percent of emissions from U.S. industrial sources in just one year. Therefore, the cumulative impacts to global warming would not be significant.

Orbital debris could be produced from BMDS space-based sensors. Orbital debris that remains on orbit could create hazards to orbiting spacecraft and could have impacts upon reentry if the debris reaches the Earth's surface in large pieces or containing hazardous materials.

Successful flight tests of the BMDS in the exoatmosphere would result in kinetic energy (i.e., hit-to-kill) intercepts that would produce both target and interceptor debris clouds. With the need for increasingly realistic test scenarios, MDA is considering high altitude, high velocity intercept tests. MDA analysis of BMDS flight tests employing ground-launched interceptors shows that the majority (90 to 95 percent) of post-intercept debris reenters the Earth's atmosphere within six hours. A small amount of post-intercept debris may become orbital debris; however, modeling indicates that risk to spacecraft from intercept debris is far lower than the risk posed by existing background debris.

Additional efforts are on-going to determine flight test risks in the space environment and resulting potential impacts on orbiting spacecraft.

The effects of orbital debris on other spacecraft would depend on the altitude, orbit, velocity, angle of impact, and mass of the debris. Debris less than 0.01 centimeter (0.004 inch) in diameter can cause surface pitting and erosion. Debris between 0.01 to 1 centimeter (0.004 and 0.4 inch) in diameter would produce significant impact damage that can be serious, depending on system vulnerability and defensive design provisions. Objects larger than one centimeter (0.4 inch) in diameter can produce catastrophic damage.

Astronauts or cosmonauts engaging in extra-vehicular activities could be vulnerable to the impact of small debris. On average, debris one millimeter (0. 04 inch) is capable of perforating current U.S. space suits.

Proposed BMDS space-based sensor activities would be expected to produce small quantities of orbital debris, primarily explosive bolts and small pieces of hardware. MDA exoatmospheric flight testing may also produce orbital debris. However, because the majority of BMDS activities would occur in Low Earth Orbit (LEO) where debris would gradually drop into successively lower orbits and eventually reenter the atmosphere, the debris would not be a permanent hazard to orbiting spacecraft. As BMDS testing becomes more realistic, there is potential for an increased amount of debris reaching and remaining on orbit. A large portion of this debris would likely not remain on orbit for more than one revolution, and eventually all of the debris would be expected to de-orbit.

Although it cannot be determined with certainty how much orbital debris would be produced from BMDS space-based sensors or intercepts annually, the fact that orbital debris reenters the Earth’s atmosphere on a daily basis, and that this debris has not caused injury or significant property damage on Earth indicates that orbital debris produced by BMDS space-based sensors and potential exoatmospheric intercepts would not pose significant impacts upon reentry. Therefore the cumulative impacts of orbital debris from Alternative 1 are not expected to be significant.

Summary of Environmental Impacts - Alternative 2

This alternative includes the use of interceptors from land-, sea-, air-, and space-based platforms. The impacts associated with the use of interceptors from land, sea, and air platforms would be the same as those discussed for Alternative 1. Therefore, the analysis for Alternative 2 focuses on the impacts of using interceptors from space-based platforms. At this time although MDA has historically conducted research and development efforts on space-based lasers, these efforts have been put on hold as kinetic energy missile technology, which is more promising in the short term, is being pursued.

If Alternative 2 were selected, additional environmental analysis would be required as the technologies intended to be used become more robust. For purposes of impacts analysis for space-based interceptors it was assumed that all manufacturing activities impacts would be the same as those discussed for Alternative 1, therefore, they are not discussed in detail for Alternative 2. Space-based interceptors would be launched on launch vehicles and maintained from platforms similar to other satellites used for DoD and commercial purposes in prescribed orbits around the Earth. The launch vehicles used to insert the weapon platforms into the proper orbit would likely be existing launch vehicles; and therefore, the impacts of the launch would be as described for support assets. A summary of potential environmental effects from Alternative 2 is provided in Exhibit ES-12.

Exhibit ES-12. Summary of Environmental Impacts of Alternative 2 – Weapons[2]

Resource Area	Interceptors	Debris
Air Quality	Emissions from space-based launches would not affect the human environment; therefore, no significant air quality impacts would be expected.	Most space-based interceptors and associated platform debris would be destroyed upon reentry. Some small particles and pieces of debris may serve as reaction sites for chemical reactions in the atmosphere. Due to the infrequency of debris reentry and deorbiting events, no significant air quality impacts would be expected.
Airspace	A space-based interceptor may be directed towards the Earth during intercepts and could impact the use of airspace in the interceptor's designated path. Coordination with the appropriate FAA ARTCC and relevant military installations with responsibility for airspace management would minimize the potential for any adverse impacts to airspace use. Therefore, no significant airspace impacts would be expected.	For controlled reentries, affected portions of airspace would be cleared of aircraft. For uncontrolled reentries, current capabilities and procedures provide a limited ability to predict when and where a particular object would reenter the Earth's atmosphere. Little advance warning could be given to clear airspace in the event of an uncontrolled reentry. However, uncontrolled reentry would occur infrequently and therefore, no significant airspace impacts would be expected.
Biological Resources	Trajectories would be carefully selected such that interceptor debris would impact in a cleared portion of the ocean or military range. It is unlikely that any interceptor debris that survives reentry would impact biological resources and no significant impacts would be expected.	Most interceptor and platform debris would be destroyed upon reentry. The debris would fall to the Earth's surface and likely terminate in open ocean waters, where impact would be limited to animals in the immediate surface waters near the impact point. Fish and marine mammals at lower depths of the ocean would have more time to react to the sound and would be able to avoid the impact area. Therefore, no significant biological resource impacts would be expected.
Geology and Soils	The launch of interceptors from space-based platforms would not impact geology and soils.	Most debris from space-based interceptors or platforms would likely not survive reentry; surviving debris would likely be very small in size. Therefore, no significant impacts would be expected to geology and soils from space-based debris.
Hazardous Materials and Hazardous Waste	The launch/flight of space-based interceptors would not produce hazardous waste that would be transported to or disposed of on Earth. Therefore, no significant hazardous material and waste impacts would be expected.	Debris contaminated with hazardous materials would be exposed to high temperatures during reentry, likely rendering the debris inert by the time it reaches the Earth's surface. Debris and deorbited material would not be considered hazardous waste. Therefore, no significant hazardous materials or waste impacts would be expected.

[2] Impacts from Alternative 2 include impacts analyzed under Alternative 1 with the addition of space-based weapons.

Exhibit ES-12. Summary of Environmental Impacts of Alternative 2 – Weapons[2]

Resource Area	Interceptors	Debris
Health and Safety	Trajectories would be selected such that, in the event of an unsuccessful intercept attempt, interceptor debris would impact in the open ocean or in designated land-based areas, which would reduce the potential for impacts to health and safety. Therefore, no significant health and safety impacts would be expected.	Trajectories would be selected such that debris would impact in the open ocean or in designated land-based areas. In the event of an uncontrolled deorbit, debris might hit and injure humans. However, the risk that an individual would be hit and injured by reentering orbital debris is estimated to be less than one in one trillion. Therefore, no significant health and safety impacts would be expected.
Noise	Launch noise from space-based launches would not be audible in the human environment and therefore, no significant impacts would be expected.	The noise produced by large pieces of debris hitting the Earth's surface might cause startle responses in nearby animals and might displace mobile species for a short time. However, as reentering debris would generally be small in size, no significant noise impacts would be expected.
Transportation	Launches from space-based platforms would not impact transportation.	Debris reaching the open ocean would most likely not be recovered. Debris recovery on land would be as described for Alternative 1, and would not have an impact on transportation.
Water Resources	Launches from space-based platforms would not impact water resources.	Debris would be rendered inert due to the high temperatures during reentry. Thus debris impacting in surface water would not impact water resources.

Test Integration

System Integration Tests would integrate existing and planned components such as sensors, weapons, C2BMC, and support assets. Under Alternative 2, System Integration Tests would involve land-, sea-, air-, and space-based platforms for weapons; and land-, sea-, air- and space-based platforms for sensors, C2BMC, and support assets.

The unique activities associated with each type of System Integration Test analyzed in this PEIS under Alternative 2 include

- **Integrated GT**. The use of additional components to control and coordinate the activities of the four weapon platforms (land-, sea-, air-, and space-based).

- **SIFT Scenario 1 – Single Weapon with Intercept**. The launch of interceptors from space-based platforms with an intercept.

- **SIFT Scenario 2 – Multiple Weapons with Multiple Intercepts**. The launch of multiple interceptors from multiple weapon platforms (land-, sea-, air-, and space-based) at up to two targets with intercepts. Under Alternative 2, the analysis assumes that the launch of a space-based interceptor would replace a land-, sea-, or air-based weapon launch or laser activation.

A summary of potential environmental effects associated with Test Integration for Alternative 2 is provided in Exhibit ES-13. The analyses are specific to each resource area based on the impacts from the activities associated with each test.

Exhibit ES-13. Summary of Environmental Impacts of Alternative 2 - Test Integration

Resource Area	SIFT Scenario 2[3]
Air Quality	If an interceptor launch from a space-based weapon replaced an interceptor launch from a land- or sea-based weapon, a reduction in ground level emissions would occur. If the activation of an air-based weapon were replaced, then a reduction in emissions would occur in the upper atmosphere. Impacts to air quality would be less than those for Alternative 1.
Airspace	If the flight path of a space-based weapon is limited to the exoatmosphere, then the impacts to airspace would be less than those for Alternative 1. If the flight path of a space-based weapon is directed toward Earth in the endoatmosphere, then the impacts to airspace would be similar to those for Alternative 1.
Biological Resources	Interceptor launches from space-based weapons would result in fewer impacts on Earth from noise and pollutant emissions. The impacts to biological resources for Alternative 2 would be less than those for Alternative 1.
Geology and Soils	If a land-based launch is replaced by a space-based launch, then the impacts to geology and soils would be less for Alternative 2 than those for Alternative 1. If a sea- or air-based launch is replaced by a space-based launch, then the impacts to airspace would be similar to those for Alternative 1.
Hazardous Materials and Hazardous Waste	Under Alternative 2, there would be a reduction of hazardous materials use, and hazardous waste generation associated with the launch or activation of a weapon. The impacts from hazardous materials and hazardous wastes for Alternative 2 would be less than those for Alternative 1.
Health and Safety	Launching an interceptor from space rather than from land, air, or sea would result in a reduction in the number of individuals that would be exposed to health and safety risks associated with launch activities. Because no significant impacts were identified under Alternative 1 from the increased use and generation of hazardous materials and hazardous waste, no significant impacts would be expected from Alternative 2.
Noise	Noise produced from the launch of interceptors from space-based platforms would not be audible on Earth. Because no significant impacts were identified under Alternative 1 from increased noise, no significant impacts would be expected from Alternative 2.
Transportation	The transportation impacts under Alternative 2 would be the same as the impacts under Alternative 1.
Water Resources	An interceptor launch from a space-based platform would replace an interceptor launch from a land-, sea-, or air-based platform, which would result in a potential reduction in the debris and simulants that would reach a water resource based on elevation where an intercept or flight termination would occur. Impacts to water resources for Alternative 2 would be less than or equal to those for Alternative 1.
Orbital Debris	Increases in orbital debris would be greater under Alternative 2 than under Alternative 1 because a higher proportion of the tests would occur in the exoatmosphere because of testing associated with space-based interceptors. However, 90 to 95 percent of debris created from exoatmospheric intercepts would reenter Earth's atmosphere within six hours. Because the debris would be on orbit for a relatively short time it would not have a significant impact on orbiting structures. In addition, only a small amount of debris would survive reentry and therefore no significant impacts would be expected.

[3] The environmental impacts associated with GTs and SIFT Scenario 1 are not presented by resource area because such impacts were not found to be substantially different from the impacts described for Alternative 1.

Cumulative Impacts

Placing interceptors in space would add additional structures to space for extended periods of time; therefore, it is appropriate to include in this cumulative impacts analysis other programs that are international in scope which place structures in space for extended periods of time. The International Space Station (ISS) was determined to be such a program. Therefore, the cumulative impacts analysis for Alternative 2 encompasses the discussion of worldwide launch programs as discussed for Alternative 1 and includes a discussion of the impacts of the proposed BMDS on and with the ISS.

Because the majority of BMDS activities would occur in LEO where debris would gradually drop into successively lower orbits and eventually reenter the atmosphere, and the orbital debris produced by BMDS activities would be small in size and in amount, orbital debris from BMDS activities would not pose a long-term hazard to the ISS. The National Aeronautics and Space Administration (NASA) and the U.S. Air Force Space Command monitor orbiting space objects and are aware of instances when the ISS is predicted to be in proximity to space debris that has the potential to damage spacecraft. Prior to every BMDS flight test, MDA assesses the risks posed to spacecraft from post-intercept debris. Launch times are selected to preclude any conjunctions between spacecraft and intercept debris. If necessary, additional analysis is conducted to determine safe launch times within launch windows thereby minimizing the risks to spacecraft. This analysis allows MDA to determine when to safely conduct a flight test. Because the proposed BMDS activities would be expected to produce small quantities of debris which would eventually be removed from orbit and because MDA would only use launch windows when the ISS would not be in the debris, there would be no significant impacts expected to the ISS from the implementation of Alternative 2 for the BMDS.

Summary of Environmental Impacts - No Action Alternative

The No Action Alternative involves the continuation of MDA activities to develop and test discrete weapons, sensors, C2BMC, and support assets and would not include System Integration Testing of these components. For the potential sites being considered for BMDS deployment, the No Action Alternative would be a continuation of activities currently occurring or planned at those locations for individual systems. Therefore, the environmental impacts on the various resource areas associated with the No Action Alternative would be the same as the impacts resulting from continued development and testing of individual missile defense elements.

The decision not to deploy a fully integrated BMDS could result in the inability to respond to a ballistic missile attack on the U.S. or its deployed forces, allies, or friends in a timely and successful manner. Further, this alternative would not meet the purpose of or need for the proposed action or the specific direction of the President and the U.S. Congress.

ACRONYMS AND ABBREVIATIONS

1 PURPOSE OF AND NEED FOR THE PROPOSED ACTION

1.1 Introduction

Pursuant to the National Environmental Policy Act (NEPA) of 1969 as amended (42 United States Code [U.S.C.] 4321, et seq.), the Council on Environmental Quality (CEQ) Regulations for Implementing the Procedural Provisions of NEPA (40 Code of Federal Regulations [CFR] 1500-1508), Department of Defense (DoD) Instruction 4715.9, *Environmental Planning and Analysis*, Presidential Executive Order (EO) 12114, Environmental Effects Abroad of Major Federal Actions, and the applicable DoD military service environmental regulations that implement these laws and regulations, all Federal agencies must consider the environmental consequences when planning for, authorizing, and approving Federal actions. Accordingly, the Missile Defense Agency (MDA) is preparing this Programmatic Environmental Impact Statement (PEIS) to examine the potential for impacts to the environment as a result of the development, test, deployment, and planning for decommissioning activities of an integrated Ballistic Missile Defense System (BMDS).

A PEIS analyzes actions that are broad in scope, occur in phases, and may be widely dispersed geographically. It also creates a comprehensive, global analytical framework that supports subsequent analysis of specific actions at specific locations within the overall system, i.e., tiering. Ranges, installations, and facilities at which specific test activities occur can develop more focused site-specific analyses that tier from this PEIS, thereby reducing analytical requirements and saving resources. This PEIS addresses the BMDS and the development and application of new technologies; evaluates the range of complex programs, architecture, and assets that comprise the BMDS; and provides the framework for future environmental analyses as activities evolve and mature. This PEIS supports the proposed integrated test schedule and considers BMDS deployment and decommissioning activities. This PEIS also considers the cumulative environmental effects that could result from the proposed action.

1.2 Background

In 1955, the United States (U.S.) began to study ways to protect against ballistic missile[1] attack. This study led to the development of the Nike-Zeus System, which accomplished the first successful intercept of a target Inter-Continental Ballistic Missile (ICBM) in 1962. Ten years later, the U.S. and the former Union of Soviet Socialist Republics (USSR) signed the Anti-Ballistic Missile (ABM) Treaty, which limited the development,

[1] A ballistic missile is a projectile traveling without its own power or guidance (like a bullet once it has been shot from a gun; the bullet travels a ballistic trajectory with only the forces of gravity and the atmosphere's friction acting on it).

testing, and deployment of ABM systems and components.[2] A 1974 amendment to the treaty further limited ABM defense deployment to one site at either an ICBM field or near the respective national capital. In 1975, the SAFEGUARD System, the only U.S. BMDS ever deployed, was activated in North Dakota. The SAFEGUARD System only operated until 1976, when it was deactivated.

In 1983, the Strategic Defense Initiative Organization (SDIO) was established within the DoD to manage and direct the research and testing of advanced technologies applicable to the development of a strategic missile defense system. These research and testing activities were known collectively as the Strategic Defense Initiative (SDI). Initially, the main purpose of SDI research concerned protecting the U.S. from weapons of mass destruction involving multiple ICBM strikes.

After the break up of the USSR and the conflict in the Persian Gulf in the early 1990's, the SDIO was refocused to emphasize protecting theater (i.e., outside the U.S.) operations and defending the U.S. against limited missile attacks (i.e., 200 warheads or less). In January 1991, President Bush described the need to acquire and deploy a Ballistic Missile Defense (BMD) system to protect not only the U.S. but also its forces overseas and its friends and allies. Subsequently, Congress provided guidance and direction to the DoD to redirect research and development for protection against ballistic missiles, regardless of their source, by enacting the Missile Defense Act.[3] In May 1993, the DoD reorganized the SDIO, renaming it the Ballistic Missile Defense Organization (BMDO).

In October 1993, the DoD completed the *Report on the Bottom-Up Review*, which reviewed the need for restructuring programs within the DoD. With respect to BMD, the review recommended the acquisition of a robust Theater Missile Defense (TMD) system[4], combined with the further development, but not the acquisition, of a more limited National Missile Defense (NMD) system. Accordingly, the DoD analyzed the proposed TMD system, its alternatives, and their potential environmental impacts in the 1993 *Final Theater Missile Defense Programmatic Life-Cycle Environmental Impact*

[2] MDA activities are in compliance with the Reduction and Limitation of Strategic Offensive Arms Treaty (START). Any mention of target ICBMs in this PEIS refers to decommissioned ICBMs.

[3] The Missile Defense Act enacted as part of the National Defense Authorization Act of 1992 (Public Law 92-190) established goals for theater and national missile defenses. It directed the DoD to develop a TMD system for possible deployment at an initial ABM Treaty-compliant site by 1996 or as soon as appropriate technology would allow. In July 1992, Secretary of Defense Cheney outlined a plan for the development and deployment of theater and national missile defenses. In passing the National Defense Authorization Act (Public Law 92-484) of 1993, Congress deleted the dates contained in the Act and in the conference report accompanying this Act; Congress endorsed a plan to deploy a limited NMD system by 2002.

[4] A theater missile is defined as "any missile (e.g., ballistic, cruise, or air-to-surface guided missile) directed against a target in an area of operations outside the U.S." (*Final Theater Missile Defense Programmatic Life cycle Environmental Impact Statement* 1993) The purpose of TMD is to "prevent or counter the launch of theater missiles against U.S. forces and allies, protect U.S. forces and allies from missiles launched against them, reduce the probability of and minimize the effects of damage caused by such an attack, and manage a coordinated response to a theater missile attack and integrate it with other combat operations."

Statement (TMD PEIS) and in the 1994 *Theater Missile Defense Extended Test Range Environmental Impact Statement* (TMD ETR EIS). The TMD PEIS included analysis of the environmental impacts of the research, development, and testing of TMD systems as well as the later life cycle phases of the system, such as production, basing, and decommissioning. The TMD ETR EIS included analysis of the environmental impacts of conducting extended-range TMD missile demonstration and operational test flights, target intercept tests, and sensor tests.

By 1994, the BMDO believed that the definition of an NMD system, as well as the technologies and resources required to implement the system, were sufficiently well understood to allow for a programmatic analysis of environmental impacts. Therefore, the BMDO issued a BMD PEIS that evaluated the environmental impacts of alternatives that would provide the U.S. the capability to produce and deploy an NMD system in the future. It further examined the cumulative environmental impacts of both the NMD and TMD systems.[5] Although the 1994 BMD PEIS ultimately selected the technology readiness (no action) alternative (i.e., the continuation of ongoing NMD activities and programs initiated under existing Congressional direction that were part of BMDO's technology readiness program) the BMD PEIS also analyzed several systems acquisition alternatives.[6] These alternatives, which involved more intensive research, development, and system-level testing as part of a program to acquire a specific defense system, included various combinations of ground-based and/or space-based elements (e.g., sensors, interceptors, and systems management tools).

Unlike the preferred technology readiness alternative, the system acquisition alternatives evaluated in the BMD PEIS had defined system architectures and descriptions of system acquisition life cycle phases. Thus, for those alternatives, the BMD PEIS evaluated potential environmental impacts of NMD activities beyond development and testing including: system production, fielding (deployment), operations and maintenance, and eventual decommissioning of facilities. The BMD PEIS programmatic analysis of the system acquisition alternatives would support “decisions on research, development, and testing activities” and thus would also serve “as the foundation from which future environmental documentation can be prepared, if needed.”

On February 16, 1996, the DoD completed another review of its BMD program. At that time, the DoD began an NMD Deployment Readiness program that would involve a shift

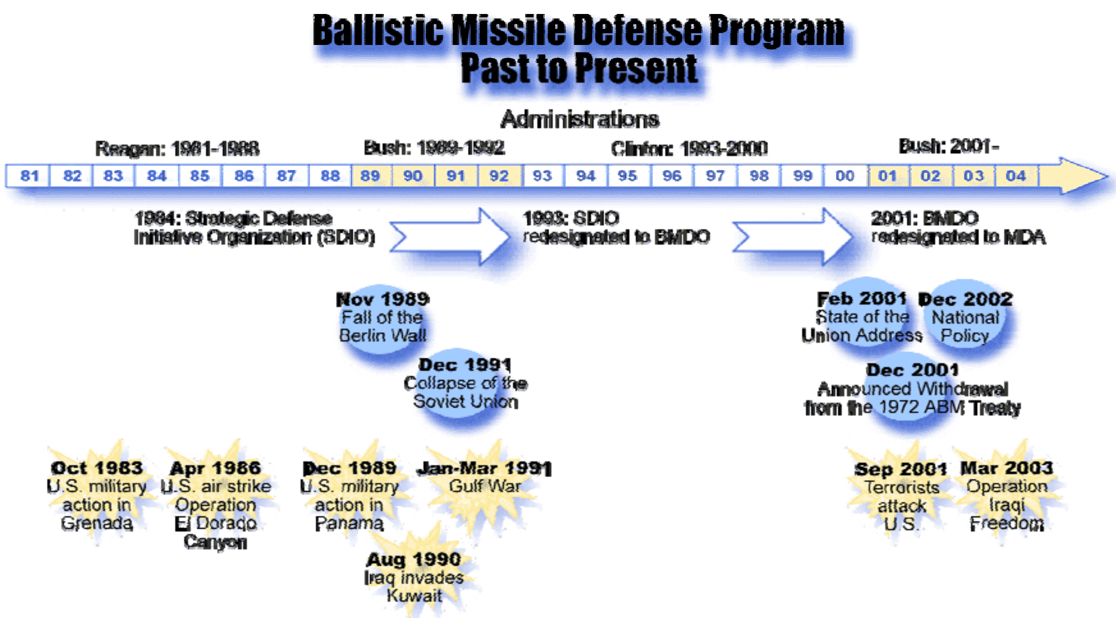
---

[5] The BMD PEIS focused more intensively on NMD because the DoD determined that the TMD program had independent utility and had already completed the TMD PEIS in 1993. The DoD incorporated the TMD PEIS by reference into the BMD PEIS, however, because the DoD intended TMD and NMD to operate as a multi-layered ballistic missile defense that would commit an appropriate interceptor, whether TMD or NMD, to defend against an attack. The BMD PEIS evaluated the combined effects of the TMD and NMD programs in a cumulative impacts analysis.

[6] Record of Decision (ROD) for the Final Programmatic Environmental Impact Statement (PEIS) for the BMD Program signed April 25, 1995.

from a technology readiness to a deployment readiness program, but without a decision to deploy an NMD system at that time. Therefore, DoD adopted a "3 plus 3" program for NMD, which would have enabled the U.S. to develop, within three years, elements of an initial NMD system that could be deployed within three years of a deployment decision. The DoD expected an NMD three-year development phase, which commenced in 1997, to culminate in a deployment readiness review in the year 2000, at which time the DoD would have decided whether to begin a three-year program to deploy an NMD system. An overview of the major events in the BMDS timeline is depicted in Exhibit 1-1.

Exhibit 1-1. Ballistic Missile Defense Timeline



On July 15, 1998, the "Commission to Assess the Ballistic Missile Threat to the United States"[7] issued a report to Congress. The report unanimously concluded that there had been concerted efforts by a number of overtly or potentially hostile nations (including North Korea, Iran, and Iraq) to acquire ballistic missiles with biological or nuclear payloads, posing a growing threat to the U.S. The report concluded that these nations would be able to inflict major destruction on the U.S. within approximately five years of a decision to acquire such a capability (10 years in the case of Iraq). The report also concluded that the threat to the U.S. posed by these emerging capabilities was broader, more mature, and evolving more rapidly than had been reported in estimates and reports by the Intelligence Community and that ultimately, the U.S. might have little or no

[7] The Commission's mandate was to "assess the nature and magnitude of the existing and emerging powers to arm ballistic missile with weapons of mass destruction." Members of the Commission were nominated by Congressional leaders and appointed by the Director of the Central Intelligence Agency.

warning before operational deployment.[8] For these reasons, the Commission unanimously recommended that "the analyses, practices, and policies" of the U.S. "that depend on expectations of extended warning of deployment be reviewed and, as appropriate, revised to reflect the reality of an environment in which there may be little or no warning."

On November 17, 1998, the BMDO published in the *Federal Register* (FR) a Notice of Intent (NOI) "to prepare an EIS for a potential NMD deployment, should the U.S. Government make such a decision."[9] The BMDO, in July 2000, issued the final Environmental Impact Statement (EIS) for NMD deployment. The proposed action identified in the final EIS was a decision to deploy and operate an NMD system consisting of five elements, including: 1) ground-based interceptors (GBIs)[10]; 2) Battle Management/Command and Control (BMC2)[11]; 3) an X-band radar (XBR)[12]; 4) an upgraded early warning radar (EWR)[13]; and 5) space-based satellite detection systems.[14] The final NMD Deployment EIS further specified that as part of a program to deploy an NMD system, a "Test, Training, and Exercise Capability" would be implemented.

In October 1999, while the draft NMD Deployment EIS was being circulated for public comment, the BMDO successfully completed its first test involving a planned intercept of

---

[8] The Commission's report also unanimously determined that the Intelligence Community's ability to provide timely and accurate estimates of ballistic missile threats was eroding and that the warning times the U.S could expect for new, threatening ballistic missile deployments were decreasing.

[9] 63 FR 63915 (1998). In the notice, the BMDO identified the technological elements of the NMD system that would be analyzed in the EIS and stated

> "The decision to be made is whether to deploy such a system. This decision will be based on an analysis of the potential limited strategic ballistic missile threat to the U.S. from a rogue nation, technical readiness of the NMD system for deployment, and other factors including potential environmental impacts. If the decision is to deploy, then sites would be selected from the range of locations studied in the EIS. The EIS will provide the U.S. Government with the information necessary to properly account for the environmental impacts of this decision."

As the BMDO further explained

> "[s]hould the deployment options not be exercised in the year 2000, improvements in NMD system element technology would continue, while an ability to deploy a system within three years of a decision would be maintained."

[10] The GBI's mission is to intercept incoming ballistic missile warheads outside the Earth's atmosphere (exoatmospheric) and destroy them by the force of the impact alone, i.e., without explosives or nuclear warheads. The GBI element includes the interceptor (i.e., missile), kill vehicle, and associated launch and support equipment, silos, facilities, and personnel.

[11] BMC2 is a sub-component of Command, Control, Battle Management and Communications (C2BMC) that supplies the means to plan, select, and adjust missions and courses of action.

[12] The XBRs would be ground-based, multi-function radars that, for NMD purposes, would perform tracking, discrimination, and kill assessments of incoming ballistic missile warheads.

[13] Early warning phased-array surveillance radars, for example, "Position and Velocity Extraction Phased Array Warning System (PAVE PAWS)," are used to detect, track, and provide early warning of sea-launched ballistic missiles. These radars also are used to track satellites and space debris.

[14] Existing DoD satellites provide the U.S. early warning satellite capability. These satellites are comparatively simple, inertially fixed, geosynchronous earth orbit (GEO) satellites with an unalterable scan pattern.

an ICBM.[15] The test demonstrated "hit-to-kill technology" to intercept and destroy the ballistic missile target. The next two tests, which were conducted in January 2000 and July 2000, respectively, did not result in an intercept.

On September 1, 2000, President Clinton announced that, due to technical uncertainties, unsuccessful flight tests, and concerns about potential implications for the ABM Treaty, he would not authorize deployment of an NMD system but would leave that decision to his successor.[16] In the interim, President Clinton stated the DoD would continue developing and testing radars and interceptors that would defend the U.S. against incoming ballistic missiles.

In early 2001 with the election of George W. Bush as President, the BMDO began to expand the test infrastructure to support greater realism in the test program and restructured the development approach into one that adopted spiral development of technologies and capabilities in coherent, incremental blocks.[17] Elements of the BMDO began development of a "test bed" in the Pacific to support this effort.[18]

Because the ABM Treaty limited the development, testing, and development of ballistic missile defense capabilities, President Bush gave Russia formal notice on December 13, 2001 that the U.S. would withdraw from the ABM Treaty in six months. On January 2, 2002, Secretary of Defense Rumsfeld issued a directive to the DoD to establish a single development program for all the work needed to design, develop, and test elements of an integrated BMDS that would operate under a newly titled MDA.[19]

To support test bed activities, MDA completed the *Ground-Based Midcourse Defense Validation of Operational Concept Environmental Assessment* (GMD Validation of

---

[15] Exoatmospheric Reentry Vehicle Interceptor System Environmental Assessment (EA), 1987, analyzed the launch of a Minuteman target from Vandenberg Air Force Base (AFB) and the launch of a GBI from the Ronald Reagan Ballistic Missile Defense Test Site (RTS), Kwajalein Atoll.
[16] On May 20, 1999 Congress passed the National Missile Defense Act to "deploy as soon as is technologically possible an effective NMD system..."
[17] "Spiral development" is an iterative process for developing the BMDS by refining program objectives as technology becomes available through research and testing with continuous feedback between MDA, the test community, and military operators. Thus, MDA can consider deployment of a missile defense system that has no specified final architecture and no set of operational requirements, but which will be improved incrementally over time. Blocks are synchronized sets of capability developments that can be added to the BMDS, build on previous blocks, and will be verified prior to transfer to the military services.
[18] "Test bed" is defined as a collection of integrated BMD element development hardware, software, prototypes, and surrogates, as well as supporting test infrastructure (e.g., instrumentation, safety/telemetry systems, and launch facilities) configured to support realistic development and testing of the BMDS.
[19] The MDA's mission is to develop, test and prepare for deployment a missile defense system. Using complementary interceptors; land-, sea-, air-, and space-based sensors; and battle management, command and control, and communications systems, the planned missile defense system will be able to engage and negate all classes and ranges of ballistic missile threats. The Secretary directed that MDA "employ a BMDS that layers defenses to intercept missiles in all phases of their flight (i.e., boost, midcourse, and terminal) against all ranges of threats."

Operational Concept EA) to construct test bed assets at Fort Greely, Alaska and at other supporting Alaska locations.[20] The GMD Validation of Operational Concept EA primarily examined ground activities regarding the construction of six GBI silos and support facilities to validate the operational concept of the test bed. The GMD Validation of Operational Concept Supplemental EA further analyzed additional infrastructure requirements necessary to support validation of the test bed operational concept.[21]

In July 2003, MDA completed the *Ground-Based Midcourse Defense Extended Test Range Environmental Impact Statement* (GMD ETR EIS), which provided for the construction and operation of additional launch and communication facilities in the Pacific test bed, and for development and operation of a sea-based X-band radar (SBX).[22]

Following continued test bed development and successful flight test activities, President Bush decided to provide the nation with an operational missile defense capability. On December 17, 2002, the President announced his decision to field an initial defensive operation (IDO) capability.[23] The initial fielding would provide a modest protection of the U.S. and would be improved over time. In view of this decision, MDA issued a Record of Decision (ROD) from the 2000 NMD Deployment EIS to support the fielding of up to 40 GBI silos at Fort Greely, Alaska.[24] In addition, the IDO capability would include four silos at Vandenberg Air Force Base (AFB). This latter action was addressed in the *Environmental Assessment for GMD Initial Defensive Operations Capability (IDOC) at Vandenberg Air Force Base (AFB).*[25]

Prior to initiation of this PEIS, MDA and its predecessor agencies prepared several programmatic NEPA documents regarding ballistic missile defense.[26] In addition, each program element prepared extensive NEPA documentation to cover its own specific, tiered documents. Ballistic missile defense has again evolved to the point that this programmatic EIS is being prepared to consider the coordinated BMDS as envisioned by the January 2002 creation of the MDA.

---

[20] The GMD Validation of Operational Concept EA Finding of No Significant Impact was signed in April 2002.

[21] The GMD Validation of Operational Concep*t* Supplemental EA Finding of No Significant Impact was signed in January 2003.

[22] The GMD ETR EIS addressed dual GBI and target capabilities at Vandenberg AFB, the RTS, Kwajalein Atoll, and the Kodiak Launch Complex (KLC) in Kodiak, Alaska. It further addressed necessary infrastructure in the Pacific to support these capabilities. There have been two RODs for actions analyzed in this EIS: 1) *ROD to Establish a GMD ETR*, dated August 2003, and 2) *Supplemental ROD to Conduct Target Launches from Kodiak Launch Complex in Support of GMD ETR*, dated November 2003.

[23] In October 2004, MDA achieved a limited missile defensive capability (LDC) when certain BMDS test components could also be placed on alert and used in defensive operations. As decisions are made based on technical performance, maturity, military utility, and national security, assets may be "placed on alert" as operational defensive capabilities. These defensive capabilities may initially be limited but could become more robust as more capability is developed or acquired.

[24] The *ROD To Establish a GMD Initial Defensive Operations Capability (IDOC) at Fort Greely, Alaska*, was finalized April 2003.

[25] The GMD IDO Capability at Vandenberg AFB Finding of No Significant Impact was signed in October 2003.

[26] The most recent programmatic documents were the 1993 TMD PEIS and the 1994 BMD PEIS.

1.3 Purpose of the Proposed Action

The purpose of the proposed action is to incrementally develop and deploy a BMDS, the performance of which can be improved over time, that layers defenses to intercept ballistic missiles of all ranges in all phases of flight.

1.4 Need for the Proposed Action

The proposed action is needed to protect the U.S., its deployed forces, friends and allies from ballistic missile threats.

In 1972, only eight countries had ballistic missiles; today there are over 30 and the threat is pervasive and proliferating. The U.S. national policy for addressing the threat of ballistic missiles and weapons of mass destruction includes a dual-path approach of both diplomatic and military measures. Diplomatically, the U.S. tries to assure our allies that we will be a dependable and strong partner for our collective security and also to dissuade or prevent potential adversaries from acquiring or developing ballistic missiles and related technologies altogether. The second path would require a non-offensive, BMDS that would protect the U.S. and its friends and allies from short-, medium-, and long-range threats.

1.5 The Proposed Action

The MDA proposes to develop, test, deploy and to plan for related decommissioning activities for an integrated BMDS using existing infrastructure and capabilities, when feasible, as well as emerging and new technologies, to meet current and evolving threats from ballistic missiles. The Secretary of Defense assigned the MDA the mission to develop and field an integrated BMDS capable of providing a layered defense for the homeland, deployed forces, friends, and allies against ballistic missiles of all ranges in all phases of flight.

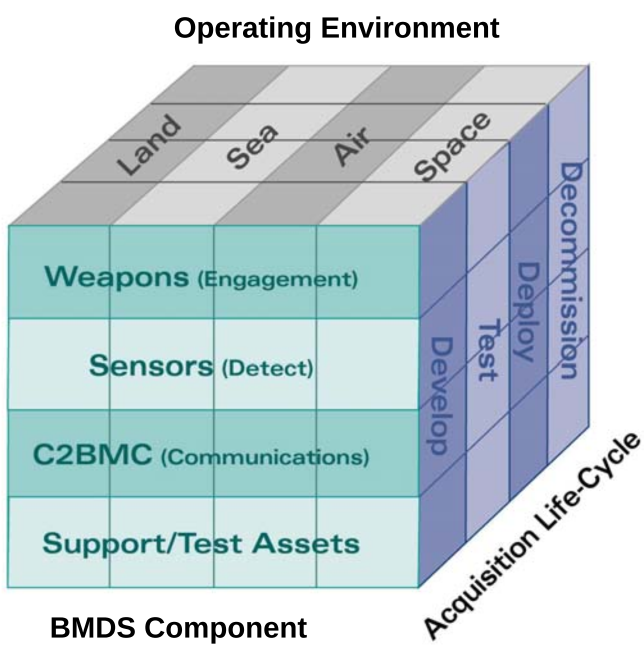
1.6 Scope of the Programmatic Environmental Impact Statement

This PEIS identifies, evaluates and documents, at the programmatic level, the potential environmental effects of the development, testing, and deployment of a BMDS, along with planning for its eventual decommissioning. Although there is already extensive environmental analysis for many of the existing and projected components of the proposed BMDS, this PEIS examines potential environmental impacts of MDA's concept for developing an integrated BMDS, based on current Congressional and Presidential direction. The BMDS PEIS will provide the framework for analyzing the development, testing and deployment of the range of complex components, architectures, and assets comprising the proposed BMDS, as well as planning for their decommissioning. The BMDS PEIS considers cumulative environmental effects that could result from the

proposed action at an appropriate programmatic level. This framework also will provide a basis from which to tier environmental impact analyses for future MDA activities.

This PEIS will address the life cycle of the proposed BMDS and its components from original research and development through planning for decommissioning. Conceptually, the BMDS is envisioned to be a layered system of weapons (i.e., interceptors and lasers), sensors (i.e., radars, infrared, optical and lasers), Command and Control, Battle Management, and Communications (C2BMC), and support assets (i.e., equipment, infrastructure and test assets), each with specific functional capabilities, working together to defend against all classes and ranges of threat ballistic missiles in the boost, midcourse, and terminal flight phases. Exhibit 1-2 depicts the multi-dimensional complexities

Exhibit 1-2. Complexities of the BMDS



involved in considering the impacts of implementing an integrated BMDS in terms of its components, acquisition life cycle activities, and operating environments.

There currently are no final or fixed architecture and no set operational requirements for the proposed BMDS. Instead, development, demonstration, and deployment of the integrated BMDS would occur over several years in an evolutionary, spiral development process designed to field an initial capability in 2004-2005 and gradually replace, enhance, or supplement this with layers of increasingly capable weapons and sensors, made possible by emerging technologies. Each new technology would go through development; promising technologies would go through testing and demonstration; and proven technologies would be incorporated into the BMDS.

Development includes the various activities that would support research and development of the BMDS components and the overall system. Development activities would include planning, budgeting, research and development, systems engineering, site preparation and construction, maintenance and sustainment, manufacture of test articles (prototypes) and initial testing, and tabletop exercises. Tabletop exercises would be used to develop and improve the Operations Concepts, the broad outline or overall picture of BMDS operations. This PEIS addresses technologies that currently are in the development stage and provides a framework for evaluating new technologies that may be developed in the future.

Testing of the BMDS involves demonstration of BMDS components through test and evaluation. The successful demonstration of the BMDS would rely on a complex testing program aimed at producing credible test data for system characterization, verification, and assessment. To confirm these capabilities, MDA would continue to develop a Test Bed using existing and new land-, sea-, air- and space-based assets. Some construction at various geographic locations would be required to support infrastructure and assets where BMDS components and the overall system would be tested. The BMDS PEIS includes ongoing and planned tests (e.g., ground tests [GTs] and flight tests) of components that might be incorporated into the BMDS, as well as tests of the layered, integrated BMDS through increasingly complex System Integration Tests including system integration flight tests (SIFTs) through 2010 and beyond.

Deployment of the BMDS refers to the fielding (including the manufacture, site preparation, construction and transport of systems) and sustainment (operations and maintenance, training, upgrades, and service life extension) of BMDS architecture. The evolving BMDS is intended to have the capability over time to deploy different combinations of interoperable sensor suites, weapons, and C2BMC. After production, some BMDS components would be transported to deployment locations. Deployment also would involve the transfer of facilities, elements, and programs to the military services. The BMDS PEIS includes start up and ongoing operations and maintenance activities that would be required at the facility locations. For some technologies and fixed assets, such as large radars, proposed deployment locations can be identified. For other technologies, such as mobile launchers and the Airborne Laser (ABL), potential deployment locations can be anticipated only in a general sense, as actual deployment decisions would depend on future geopolitical conditions and security concerns. Although the operational life of some BMDS technologies can be estimated, it is difficult to estimate for many proposed technologies given both the uncertainty of their development and deployment schedules as well as the potential for technology upgrades and service life extensions.

Decommissioning would involve the demilitarization and final removal and disposal of the BMDS components and assets. Plans would be made for decommissioning BMDS components by either demolition or transfer to other uses or owners.

Typical activities involved in developing, testing, deploying and planning for decommissioning the proposed BMDS are identified in Exhibit 1-3.

Exhibit 1-3. Typical Activities for BMDS Proposed Action

1.7 Consultations and Coordination

As the lead agency, MDA has primary responsibility for preparing the PEIS. As part of the scoping process, the lead agency is required to consult with affected Federal, state, local, and tribal agencies, and other interested parties. A continuing relationship with affected and interested entities can be established to promote cooperation and resolution of mutual land-use and environment-related problems, and to promote the concept of

regional ecosystem management as well as general cooperative problem solving. The agencies involved in this process are referred to as coordinating or consulting agencies.

Consulting agencies do not enter into a legal agreement with the lead agency. Consulting agencies may submit comments and provide data to support the environmental analysis, but they do not participate in the internal review of documents, issues, and analyses. A consulting agency does not participate directly in the development of technical analyses and conclusions.

The MDA has identified several agencies that may be coordinating or consulting agencies for this PEIS. These agencies include: National Oceanic and Atmospheric Administration National Marine Fisheries Service (NOAA Fisheries Service), the Advisory Council on Historic Preservation (ACHP), U.S. Fish and Wildlife Service, and the U.S. Federal Aviation Administration (FAA).

A cooperating agency is any Federal agency, other than a lead agency, that has jurisdiction by law or special expertise with respect to any environmental impact involved in a proposal (or reasonable alternative) for legislation or other major Federal action significantly affecting the quality of the human environment. (40 CFR Part 1508.5) The MDA has held informal meetings with several agencies; however, MDA has not requested that any agencies participate as cooperating agencies for this PEIS. See Appendix A for additional information on consultation and coordination.

1.8 Summary of the Public Involvement Process

The MDA provided several opportunities and means for public involvement during scoping and throughout the preparation of the BMDS PEIS. The CEQ implementing regulations for NEPA describe the public involvement requirements for agencies (40 CFR 1506.6). Public participation in the NEPA process not only provides for and encourages open communication between the MDA and the public, but also promotes better decision-making. Throughout the preparation and review of the Draft BMDS PEIS, the MDA aimed to obtain meaningful input concerning the issues that should be addressed.

1.8.1 Scoping

Scoping for the development of the BMDS PEIS began with the publication of the NOI in the FR (68 FR 17784) on April 11, 2003. See Appendix B for a detailed description of scoping and a copy of the NOI. During scoping, the MDA invited the participation of Federal, state, and local agencies, Native American Tribes, environmental groups, organizations, citizens, and other interested parties to assist in determining the scope and significant issues to be evaluated in the BMDS PEIS. The MDA developed a web site, http://www.mda.mil/mdalink/html/mdalink.html, to provide information on the BMDS PEIS and to solicit scoping comments. The MDA also established toll-free phone and

fax lines, an e-mail address, and a U.S. postal service mailbox for submittal of public comments and questions.

MDA held public scoping meetings in accordance with CEQ regulations. (40 CFR 1501.7) Meetings took place in Arlington, Virginia on April 30, 2003; Sacramento, California on May 6, 2003; Anchorage, Alaska on May 8, 2003; and Honolulu, Hawaii on May 13, 2003. The purpose of the scoping meetings was to request input from the public on concerns regarding the proposed activities as well as to gather information and knowledge of issues relevant to analyzing the environmental impacts of the BMDS. The public scoping meetings also provided the public with an opportunity to learn more about the MDA's proposed action and alternatives. In addition to announcing the public scoping meetings in the NOI, the MDA placed legal notices in local and regional newspapers and notified state governors, mayors, members of Congress and local media representatives about the scoping meetings. See Appendix B for additional information on public involvement.

During scoping, the MDA received 285 comments. The MDA requested scoping comments be submitted by June 12, 2003, to be considered in developing the Draft BMDS PEIS. The majority of comments were related to opposition to the BMDS, especially with regard to the use of space as a weapons platform; concern that the program would bankrupt the economy and that Federal funds should be channeled to address socioeconomic problems, better health care and insurance coverage, and education; and concern that the BMDS would create an arms race, especially in space. Other key issues included opposition to development of nuclear weapons and concern that missile defense could be a first strike capability for U.S. worldwide military domination. Public comments concerning DoD policy, budget, and program issues are outside the scope of the Draft BMDS PEIS. Comments received pertaining to reasonable alternatives to the proposed action, resource areas, human health, and environmental impacts were considered in this BMDS PEIS. See Appendix B for comment excerpts related to resource areas and human health and environmental impacts.

1.8.2 Public Comment Period

The public comment period began with the publication of the Notice of Availability (NOA), published in the FR by the Environmental Protection Agency (EPA) on September 17, 2004. The NOA announced the availability of the Draft PEIS, initiated the public comment period for the NEPA process, and requested comments on the Draft PEIS. The MDA also published a NOA in the FR on September 17, 2004, which provided information on the proposed action and alternatives, listed the dates and locations of the public hearings, and provided contact information for submitting comments to the MDA. See Appendix B for a detailed description of the public comment period and a copy of the NOA.

A downloadable version of the Draft PEIS was available on the BMDS PEIS web site and hardcopies of the document were placed in the following public libraries:

- Anchorage Municipal Library, 3600 Denali Street, Anchorage, AK 99503
- Mountain View Branch Library, 150 South Bragaw Street, Anchorage, AK 99508
- California State Library, Library and Courts Building, 914 Capital Mall, Sacramento, CA 95814
- Sacramento Public Library, 828 I Street, Sacramento, CA 95814
- Hawaii State Library, Hawaii Documents Center, 478 South King Street, Honolulu, HI 96813
- University of Hawaii at Manoa, Hamilton Library, 2550 The Mall, Honolulu, HI 96822
- Arlington County Public Library, Central Branch, 1015 North Quincy Street, Arlington, VA 22201
- District of Columbia Public Library, Central Branch – Martin Luther King, Jr. Memorial Library, 901 G Street, NW, Washington, DC 20001

MDA held public hearings in Arlington, Virginia on October 14, 2004; Sacramento, California on October 19, 2004; Anchorage, Alaska on October 21, 2004; and Honolulu, Hawaii on October 26, 2004. In addition to announcing the public hearings in the NOA, the MDA placed legal notices in local and regional newspapers and notified state governors, mayors, and members of Congress. See Appendix B for additional information on the public hearing notification process.

The purpose of the public hearings was to solicit comments on the environmental areas analyzed and considered in the Draft PEIS. Appendix B contains a reproduction of the transcripts of the public hearings.

During the public review period, the MDA received approximately 8,500 comments on the Draft PEIS. See Appendix K for an overview of comments received on the Draft PEIS and the MDA's responses to in-scope comments. Additional areas of analysis—orbital debris, perchlorate, and radar impacts to wildlife—are addressed in more technical detail in Appendices L, M, and N, respectively.

1.9 Related Documentation

Existing relevant NEPA analysis and health and safety documentation is incorporated by reference. These documents are listed in Appendix C, Related Documentation. The relevant information and analyses contained in these documents is summarized in this PEIS where appropriate.

This page intentionally left blank.

2 DESCRIPTION OF PROPOSED ACTION AND ALTERNATIVES

The proposed action is to develop, test, deploy, and to plan for decommissioning activities for an integrated BMDS using existing infrastructure and capabilities, when feasible, as well as emerging and new technologies, to meet current and evolving threats in support of the MDA's mission.

2.1 BMDS Concept

The BMDS is designed to negate threat ballistic missiles of all ranges in all phases of flight. To achieve this mission, the BMDS would be made up of **components** (i.e., weapons; sensors; C2BMC; and support assets). These components would be

> ***Component***: Subsystem, assembly, or subassembly of logically grouped hardware and software, that performs interacting tasks to provide BMDS capability at a functional level.

assembled into programs known as **elements**, which can operate independently or together to defeat a threat missile.

> ***Element:*** A functional set of integrated components comprising a stand-alone defensive capability**.** The elements provide "blueprints" for some of the specific functional capabilities that would be included in the proposed BMDS. However, the configuration of these elements is dependent upon the ongoing testing and enhancement of their components.

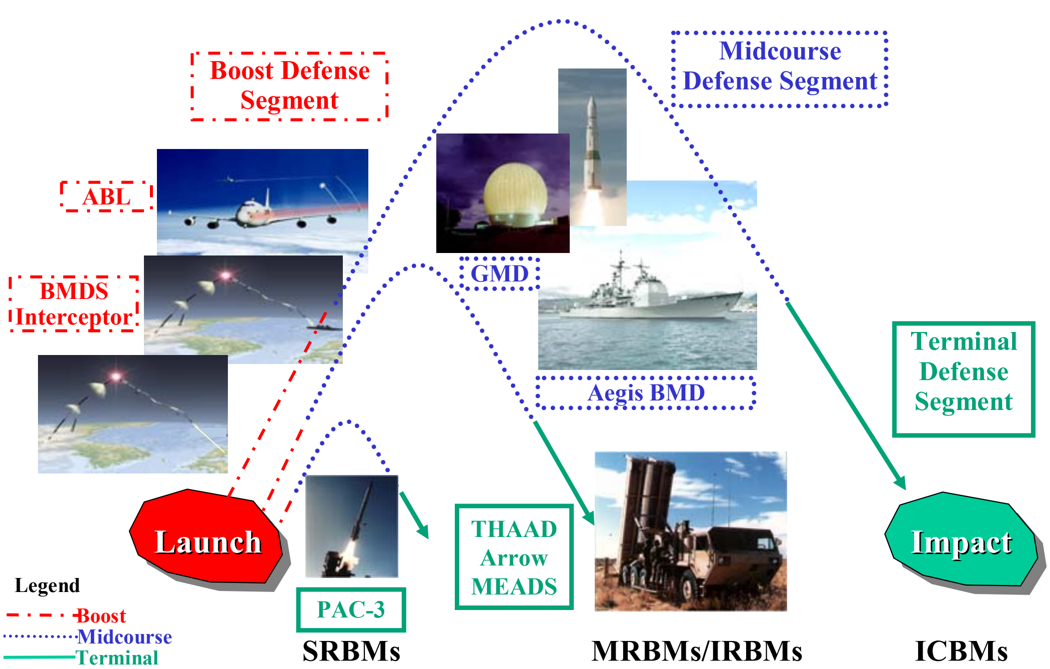
Multiple defensive weapons are required to create a layered defense comprised of multiple intercept or shot opportunities along the incoming threat missile's trajectory. These weapons would be used from a variety of platforms (i.e., any military structure or vehicle bearing weapons). This layered defense would provide a defensive system of capabilities that could back up one another. For example, one element could engage a threat missile in its boost phase and other elements could be used to intercept the threat missile in later phases if initial intercept attempts were unsuccessful. As shown in Exhibit 2-1, ballistic missiles can be categorized based on their approximate flight distances.

Exhibit 2-1. Types and Maximum Ranges of Ballistic Missiles

Type of Ballistic Missile	Approximate Flight Distance in kilometers (miles)
Short Range Ballistic Missile	600 (373)
Medium Range Ballistic Missile	1,300 (808)
Intermediate Range Ballistic Missile	5,500 (3,418)
Inter-Continental Ballistic Missile (ICBM)	10,000 (6,214)

Each type of ballistic missile has three distinct phases of flight: boost, midcourse, and terminal. A flight phase is a portion of the path followed by an object moving through the atmosphere or space. Each phase of flight presents its own challenges to a defensive intercept due to variations in speed, configuration, altitude, and range. The proposed BMDS is envisioned to be capable of defending against all classes of threat ballistic missiles in all phases of flight. Exhibit 2-2 presents missile flight phases also defined as defense segments with the existing BMDS elements designed to operate in them. Please refer to the legend on Exhibit 2-2 to identify the elements that are in the various flight phases or defense segments.

Exhibit 2-2. Ballistic Missile Flight Phases and Defense Segments



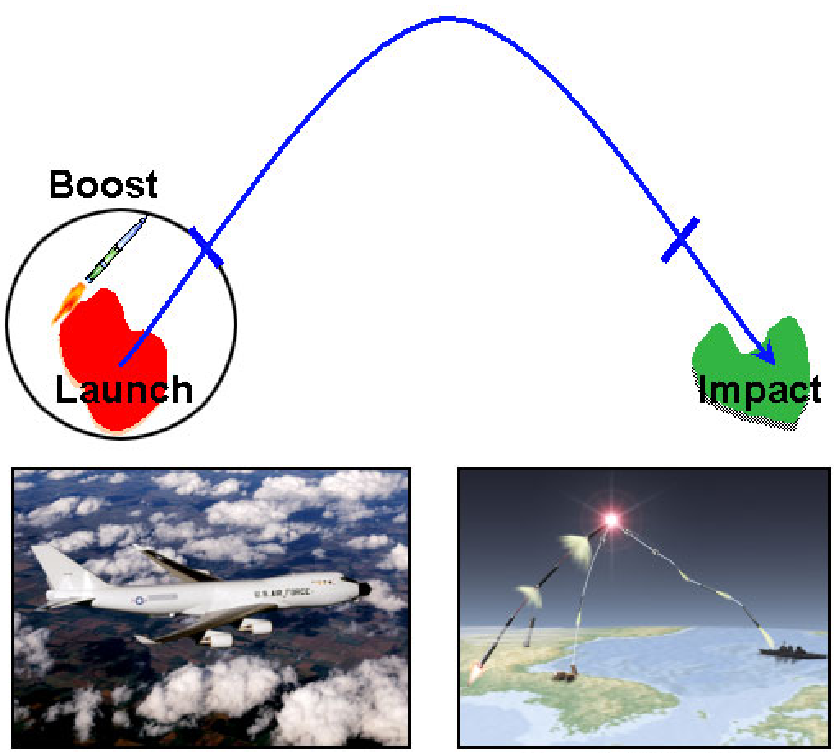
The following section describes each of the three phases of ballistic missile flight, and the currently configured or planned program elements within the BMDS that are designed to address the threat missile within that phase. An overview of the program elements is provided in Appendix D.

2.1.1 BMDS Layered Defense and Missile Flight Phases

2.1.1.1 Boost Phase and the Boost Defense Segment

The ***Boost Phase*** (see Exhibit 2-3) is the first phase of a ballistic missile trajectory, when the rocket engine is ignited and the missile is lifting off and setting out on a specific path. The missile is powered by its engines throughout this phase.

Exhibit 2-3. Boost Phase and the Boost Defense Segment



Airborne Laser

Terrestrial Test Bed
Kinetic Energy Interceptor

- Ballistic missiles are most vulnerable during boost – relatively easy to find and moving slowly
- BMDS needs to be alerted and positioned near the enemy launch site to engage in boost phase
- Requires quick reaction times, high confidence decision making, and multiple engagement capabilities
- Missile is within Earth's atmosphere (endoatmosphere)
- Boost phase lasts about 180 to 600 seconds
- Key elements: ABL and Kinetic Energy Interceptor (KEI)

Currently configured or planned BMDS elements in the boost defense segment include

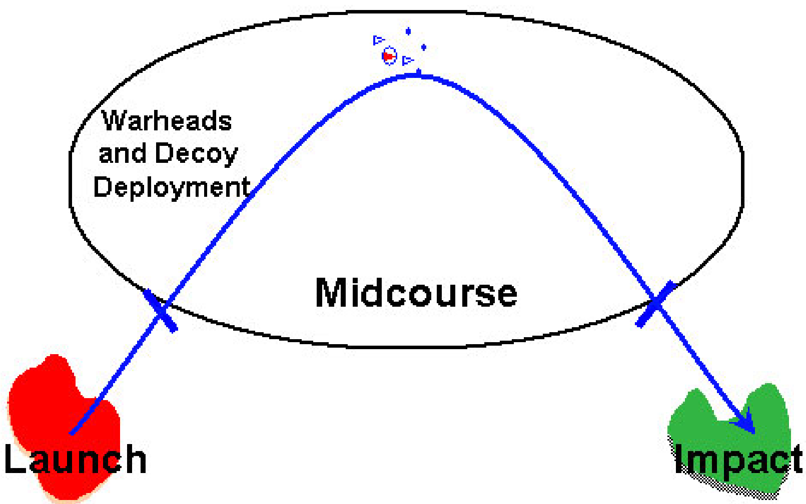
Airborne Laser (ABL). The ABL involves putting a weapons class laser aboard a modified Boeing 747 aircraft and using that laser to destroy enemy ballistic missiles in the boost phase.

Kinetic Energy Interceptor (KEI or BMDS Interceptor). The primary objective of the KEI or BMDS Interceptor program is to develop an interceptor capable of destroying ICBMs in the boost phase.

2.1.1.2 Midcourse Phase and the Midcourse Defense Segment

The *Midcourse Phase* (see Exhibit 2-4) begins when the rocket engine cuts off and the threat missile travels a ballistic trajectory. During this phase, the threat missile is approximately 100 kilometers (62 miles) above Earth's surface. At this point it could deploy decoys to confuse detection and discrimination systems and/or a warhead that continues on the missile's trajectory towards its target.

Exhibit 2-4. Midcourse Phase and the Midcourse Defense Segment



Ground-Based
Interceptor Launch

Aegis BMD

- Ballistic missiles "coast" for several minutes during midcourse and may deploy warheads and decoys
- BMDS uses multiple sensors to determine "real" threat and directs weapons to destroy threat objects in space
- Threat missile is about 100 kilometers above the Earth's surface (exoatmosphere)
- Midcourse phase lasts about 1200 seconds
- Key elements: Ground-Based Midcourse (GMD) and Aegis BMD

BMDS elements currently configured to comprise the midcourse defense segment include

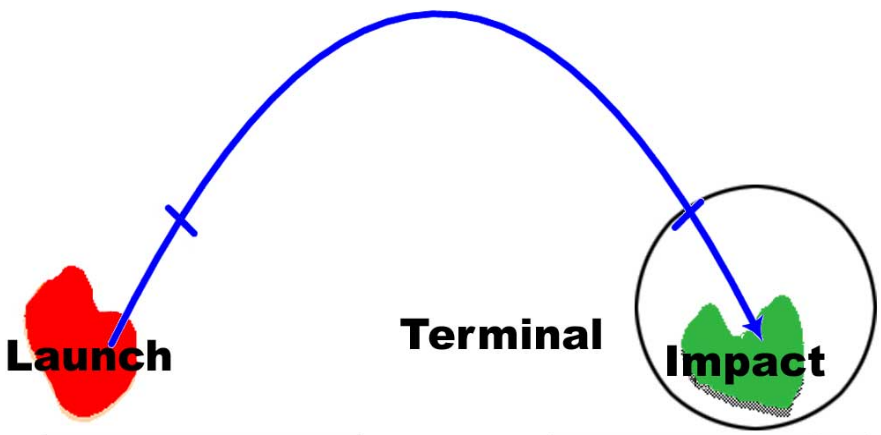
Ground-Based Midcourse Defense (GMD). The GMD mission is to defend against long-range ballistic missile attacks, using its weapon, the GBI, to defeat threat missiles during the midcourse segment of flight.

Aegis Ballistic Missile Defense (Aegis BMD). The Aegis BMD will provide the capability for Navy Aegis cruisers to use hit-to-kill technology to intercept and destroy short- and medium-range ballistic missiles.

2.1.1.3 Terminal Phase and the Terminal Defense Segment

The ***Terminal Phase*** (see Exhibit 2-5) begins as the deployed warhead or the missile continues along its ballistic trajectory towards trajectory termination.

Exhibit 2-5. Terminal Phase and the Terminal Defense Segment



Terminal High Altitude Area Defense (THAAD) Launch

PATRIOT Advanced Capability (PAC)-3

- Ballistic missile is seconds away from its intended target as it approaches trajectory termination
- BMDS "last line of defense" - defensive systems must be positioned near area to be protected (e.g., city, airfield)
- Terminal phase lasts about 30 seconds
- Key elements: PATRIOT Advanced Capability – 3 (PAC-3), Terminal High Altitude Area Defense (THAAD), Israeli Arrow Weapon System, Multi-national Medium Extended Air Defense System (MEADS)

BMDS elements currently configured or planned for the terminal defense segment include

PATRIOT Advanced Capability-3 (PAC-3). PAC-3 is a mobile and transportable land-based missile defense element that is capable of multiple simultaneous engagements of short- and medium-range ballistic missiles and can operate in electronic countermeasure environments.

Terminal High Altitude Area Defense (THAAD). THAAD is designed to destroy a ballistic missile as it transitions from the mid-course to terminal phase of its trajectory both inside and outside of the atmosphere (in the endo- or exoatmosphere). THAAD is a land-based element that has the capability to shoot down a short- or medium-range ballistic missile and has rapid mobility to provide a means of defense anywhere in the world in a short timeframe.

Arrow Weapon System (AWS). The AWS is a cooperative effort between the U.S. and the Government of Israel to develop a missile defense system to protect the State of Israel and U.S. and allied forces deployed in the Middle East Region. The AWS is a ground-based missile defense system capable of tracking and destroying multiple short- and medium-range ballistic missiles in the terminal phase of their flight.

Medium Extended Air Defense System (MEADS). The MEADS program is a transatlantic cooperative effort between the U.S., Germany, and Italy to develop an air and missile defense system that is strategically transportable and tactically mobile. MEADS will defend population centers, vital assets, and forces by countering short- and medium-range ballistic missile threats in the terminal phase of their flight. MEADS will integrate the PAC-3 hit-to-kill interceptor into a system that can move with and protect forces as they maneuver in combat.

2.1.2 BMDS Functional Capabilities

The ability of the proposed BMDS to achieve a layered defense can be described in terms of ***functional capabilities***. The functional capabilities of the BMDS would be developed with the objective of deploying an initial set of capabilities by 2004-2005 and enhancing these capabilities over time.

Functional capabilities: The capability of the proposed BMDS to detect, identify, track, discriminate, intercept, and destroy a threat ballistic missile during a specific phase of flight (i.e., boost, midcourse, or terminal). Functional capabilities are the abilities to negate specific ballistic missile threats.

The functional capabilities of the proposed BMDS include the long-term flexibility of the BMDS to evolve to meet future threats. To engage a threat, an **engagement sequence** is needed.

> ***Engagement Sequence*:** A unique combination of detect-control-engage functions performed by BMDS components (e.g., sensors, weapons, and C2BMC equipment) used to engage a threat ballistic missile. The command and control, battle management, and fire control functions enable the engagement sequence.

Combinations of these capabilities with common characteristics, called **engagement sequence groups (ESGs)**, may be used to simplify the specification of BMDS capabilities and to more easily assess system performance during testing and operations.

> ***Engagement Sequence Group (ESG):*** The logical categorization of engagement sequences based upon common capabilities or characteristics (e.g., sensors, weapons, and C2BMC equipment) that perform overlapping or similar functions in the execution of an engagement. Using ESGs as a tool enhances functional and engineering analysis, creates manageable combinations for Initial Defensive Operations and Block configurations, simplifies allocation of BMDS capabilities, provides a structure to assess BMDS performance, and assists the warfighter in operating the BMDS.

The BMDS would need to

1. Provide input for missile defense battle management decisions

The BMDS should provide a way to decide when a foreign missile launch poses a threat that warrants a response, what response to take, and when the threat has been negated. The BMDS must be able to obtain the necessary information and provide it to the decision-maker in a timely manner. Functional capabilities needed to provide the information include the ability to

- Detect threat missile launches,
- Determine threat posed by missile (including type of warhead and potential payload),
- Track missile flight path,
- Predict threat impact location(s),
- Communicate with defensive weapons to direct the intercept, and
- Detect/assess the intercept.

2. Negate threat missiles during flight

The BMDS should have the capability to destroy threat missiles anywhere along the flight trajectory. Functional capabilities that the BMDS must have to destroy threat missiles include the ability to

- Launch a defensive weapon,
- Overcome any countermeasures released by a threat missile,
- Guide defensive weapon to critical point,
- Engage threat missile, and
- Negate threat payload.

3. Provide multiple engagement opportunities during flight

The BMDS should provide multiple engagement opportunities along a flight path. Threat missiles evading initial intercept attempts could be negated by subsequent attempts. This capability also provides opportunities to destroy the threat while it is over enemy territory (i.e., during boost) or over sparsely populated areas (i.e., during midcourse flight). Functional capabilities needed to provide multiple engagement opportunities include the ability to

- Coordinate and manage multiple weapon launches,
- Sustain/maintain launch facilities, and
- Engage threat missile in all flight phases.

4. Provide robust defense against evolving threats

The BMDS should have the capability to adjust to a constantly evolving threat environment. Enemies will adjust and develop their offensive tactics and capabilities. Changing political situations may shift where threat missiles may be launched and the theater of operations the BMDS must protect. Functional capabilities that must be developed to defend against evolving threats include

- Interoperable technologies that can work in various combinations, and
- Interoperable technologies that are deployable where needed.

According to the functional capabilities currently identified for the proposed BMDS, the system would detect, identify, track, discriminate, engage, and destroy ballistic missiles in all phases of flight that threaten the U.S. and its deployed forces, allies, and friends. To achieve these functional capabilities, the proposed BMDS would be a system of integrated technologies, or **components,** that are greater than the sum of the current defensive elements. The components of the BMDS are

- Weapons (i.e., interceptors and lasers),
- Sensors (i.e., radars, infrared, optical, and lasers),
- C2BMC, and
- Support Assets (i.e., auxiliary equipment, infrastructure, and test assets).

Individual components can be thought of as “tools” or “building blocks” that could be combined in different ways to meet the required functional capabilities of the proposed BMDS. Components would contribute to the functional capabilities as described in Exhibit 2-6.

Exhibit 2-6. Crosswalk of Functional Capability with Components

FUNCTIONAL CAPABILITY	COMPONENTS			
	Weapons	**Sensors**	**C2BMC**	**Support Assets**
1. Input for Missile Defense Battle Management Decision				
Detect Threat Missile Launches		X		X
Determine Threat Posed by Missile		X	X	X
Track Missile Flight Path		X		X
Predict Impact Location		X	X	X
Communicate with Other Elements and Weapon System	X	X	X	X
Detect/Assess Intercept		X	X	X
2. Negate Threat Missiles During Flight

Exhibit 2-6. Crosswalk of Functional Capability with Components

FUNCTIONAL CAPABILITY	COMPONENTS			
	Weapons	**Sensors**	**C2BMC**	**Support Assets**
Engage Threat Missile in All Flight Phases	X	X	X	X
4. Provide Robust Defense Against Evolving Threats				
Interoperability of Components	X	X	X	X
Deployable Where Needed	X	X	X	X

The BMDS functional capabilities would evolve over time in response to newly defined threats and technology developments. As the functional capabilities change, individual components and elements would be enhanced with new technologies to meet those threats. The evolution of the proposed BMDS is described in Section 2.1.3 BMDS System Acquisition Process below.

2.1.3 BMDS System Acquisition Approach

2.1.3.1 Traditional Approach to Missile Defense Acquisition

The system acquisition process for evolving defensive systems historically required defined system architectures. Under the traditional approach, the MDA primarily focused on developing single elements and associated technologies that could provide independent defensive military utility. These stand-alone elements can be characterized as packages of components, typically comprised of sensors, a weapon, accompanying C2BMC hardware and software, and support assets.

The traditional acquisition process focused on developing, testing, and procuring individual elements with certain functional defensive capabilities. However, this process can also require a rigid adherence to a defined life cycle. All components of an element must meet all existing weapons acquisition specific test, development, and operational requirements before the element can be produced and procured. This inflexible process can be redundant and inefficient as technical challenges associated with one component might delay the progress of other components in an element. The initial focus of the DoD on developing and acquiring elements resulted in several NEPA analyses to support the development, testing, and procurement of the proposed defensive elements and their components. Detailed discussions of these elements can be found in Appendix D.

2.1.3.2 New Approach to Proposed BMDS

The MDA, as the acquisition agency for the BMDS, has implemented a new, more flexible approach to developing the proposed BMDS. This approach is capability-driven and component-based rather than focused on specific elements or programs. Capability-based planning allows MDA to develop capabilities and objectives based on technology feasibility, engineering analyses, and the capability of the threat. This development involves an iterative process known as spiral development that refines program objectives as technology becomes available through research and testing with continuous feedback between MDA, the test community, and the military operators. Thus MDA can consider deployment of a missile defense system that has no specified final architecture and no set operational requirements but which will be improved incrementally over time.

MDA's approach to accomplish the goal of developing an integrated, layered BMDS capable of engaging enemy ballistic missiles of all ranges during the boost, midcourse and terminal phases of flight would focus on

- Fielding an initial defensive capability (IDC) in accordance with the President's direction;
- Adding interceptors and networked, forward-deployed ground-, sea- and space-based sensors to make the interceptors more effective in 2006-2007; and
- Adding layers of increasingly capable weapons and sensors, made possible by inserting emerging technologies.

The approach for incremental improvement involves

- Determining functional capability needs,
- Identifying potential ways to meet these needs with new and/or enhanced components,
- Using a spiral development process to develop, test, and identify new technologies, and
- Fielding only those new and/or enhanced components with proven ability to meet the identified functional capability needs.

Spiral development begins when a desired functional capability is identified. The ability of existing components and emerging technologies to meet the functional capability would be reviewed and efforts to develop or enhance specific components would be initiated. Testing and ongoing modification would be used to determine the ability of each component to meet the functional capability needs. For example, new components would undergo initial development or proof-of-concept testing, while existing components would be tested to determine their readiness for use. Work on a given technology improvement would stop if testing failed to demonstrate effectiveness or functional capability needs changed.

The process is organized into two-year time windows, or **Blocks**, consisting of packages of capabilities that are being developed over several years. For example, Block 2004 represents years 2004-2005, and Block 2006 represents years 2006-2007. During each Block, the MDA would research, develop, and test components in varying stages of development.

> ***Block***: A block is a two-year increment of the BMDS providing an integrated set of capabilities, which has been rigorously tested as part of the BMDS Test Bed and assessed to adequately characterize its military utility. The configuration for each block is drawn from the prior BMDS Block; BMDS elements, components, technologies, and concepts; C2BMC architecture; and externally managed systems, elements or technologies.

Thus, the development and testing of individual components to meet a specific BMDS functional capability would "spiral" through several successive Blocks (see Exhibit 2-7). When appropriate, spiral development within block increments would help keep pace with useful technology improvements, reduce risk through iterative reviews, and match user expectations with delivered performance to provide improved capabilities as quickly as possible. Eventually, some components would be transitioned to the military service responsible for deployment, operation and maintenance. Evolutionary acquisition in block increments would provide a practical approach to aggressively develop and field early BMDS capabilities while preserving flexibility to respond to evolving ballistic missile threats and incorporate improved technology.

Exhibit 2-7. Block Development Process

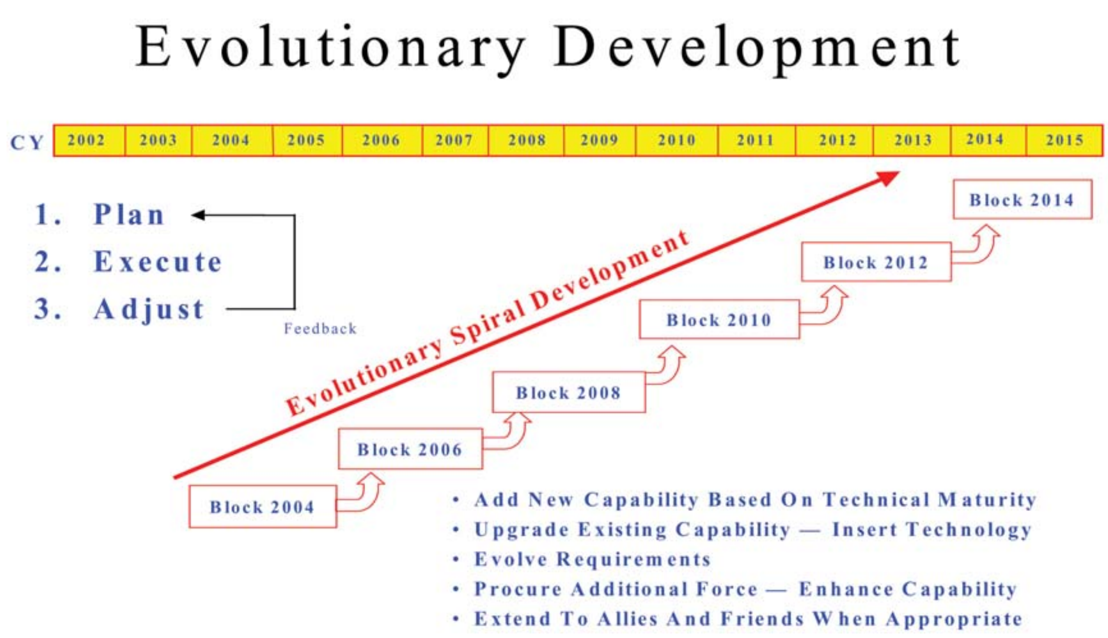

Exhibit 2-8 shows spiral development via the systems engineering process.

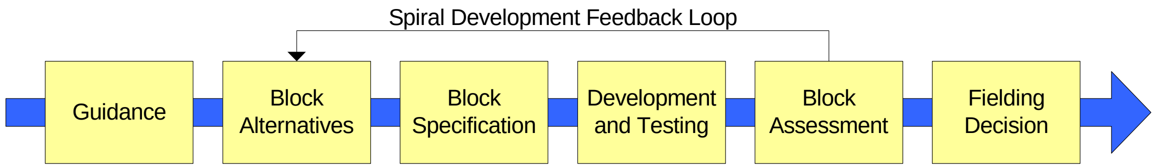
Exhibit 2-8. The MDA Systems Engineering Process



The engineering principle for organizing and discussing the BMDS capability is the ESG, which is a means to categorize or group similar engagement sequences based on capability or function. An engagement sequence is a unique combination of detect-control-engage functions performed by BMDS components used to engage a threat ballistic missile; it would define a specific detection sensor, specific fire control radar and specific weapon. ESGs define the sequence of events, functions, and system components used to enable a weapon to engage a target and provide the structure for measuring the level of performance and integration maturity of the BMDS. ESGs also relate multiple ways of engaging a target.

An example of an ESG is an intercept scenario in which the GBI would receive its final target update from the COBRA DANE Radar. As the BMDS grows in complexity, i.e., integration of many elements and components, the number of ESGs will increase, thereby increasing system capability. Better information about the threat from additional sensors and more chances to destroy the threat from additional weapons will also result in enhanced system performance. Using ESG as a tool enhances functional and engineering analysis creates manageable combinations for Block configurations, simplifies allocation of BMDS capabilities, provides a structure to assess BMDS performance, and assists the warfighter in operating the BMDS.

2.2 BMDS Components

The components of the proposed BMDS are weapons, sensors, C2BMC, and support assets that as part of the existing or envisioned elements can provide the functional capabilities of the BMDS. The proposed BMDS would integrate components in a unified system. The general characteristics of these components are described in the following sections. Descriptions of components of existing elements are provided in Appendix D.

2.2.1 Weapons

Weapons are the components of the BMDS that can be used to destroy threat missiles. For the BMDS, weapons consist of various types of interceptors and directed energy weapons (e.g., high energy lasers [HELs]). Interceptors would use two primary kinetic energy technologies, hit-to-kill or direct impact and directed fragmentation.

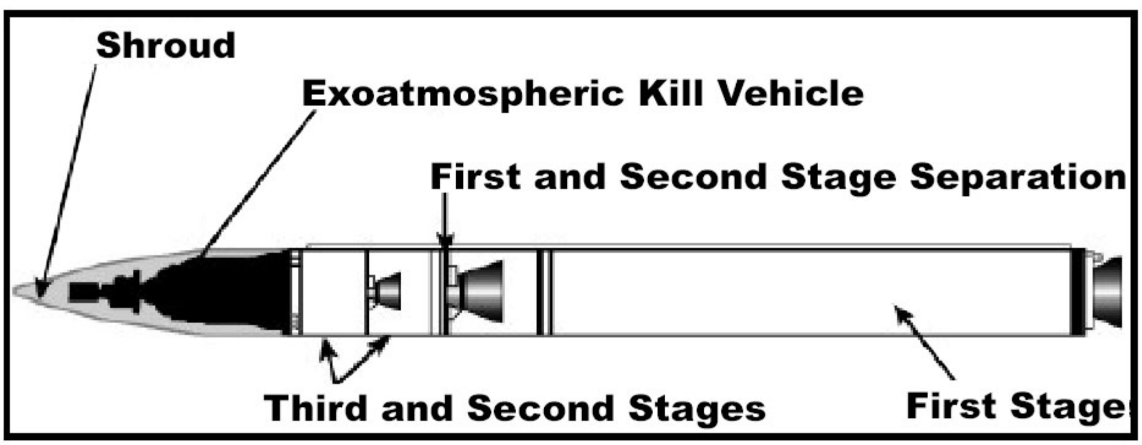
Interceptors must conduct multiple tasks simultaneously, adjust flight path accurately, discriminate the reentry vehicle from countermeasures, and engage and negate the threat missile. BMDS interceptors could be placed on land, sea-, air-, or space-based platforms. BMDS directed energy systems are currently envisioned to perform target illumination and tracking and to negate threat missiles from an air-based platform, although they could also be placed on land-, sea-, or space-based platforms.

2.2.1.1 Weapons Technologies and Subcomponents

Interceptors

Interceptors use kinetic energy either in a direct impact or hit-to-kill mode, or to deflect or possibly destroy a threat missile by directed blast fragmentation. Interceptors are composed of two primary parts, a booster and a kill vehicle (see Exhibit 2-9). An interceptor may have one or more boosters (also called stages). The number of boosters or stages refers to the number of rocket motors that sequentially activate. Multiple stages allow the interceptor to fly at higher velocities and altitudes, and for longer distances. The kill vehicle is the portion of the interceptor that performs the intercept and destroys the threat missile. It is anticipated that solid and liquid propellants would be used in the boosters and in the kill vehicles. For the purposes of this PEIS, interceptors will be discussed and analyzed for environmental impacts at the booster and kill vehicle level. This will allow the MDA the flexibility to configure new interceptors based on boosters and kill vehicles analyzed in this document to address new or emerging threats.

Exhibit 2-9. Interceptor Schematic



Interceptors may also use lethality enhancers, seekers, and attitude control systems. Lethality enhancers are non-nuclear explosive devices that increase the probability of destroying the threat missile and its payload (e.g., explosives, chemical or biological agents). Seekers help to detect the threat missile and home in on it. Attitude controls are small motors used to modify the flight path of the kill vehicle and position it into the

flight path of the threat missile. All of these are important parts of interceptors and the environmental impacts from their use will be considered as part of the analysis of boosters and kill vehicles in this PEIS.

Boosters use two broad classes of propellants: solid and liquid. Propellants consist of a fuel and oxidizer. An oxidizer is a substance such as perchlorate, permanganate, peroxide, and nitrate that yields oxygen readily to support the combustion of organic matter, powdered metals and other flammable material. Boosters can use liquid hydrocarbon propellants (e.g., kerosene) plus an oxidizer such as liquid oxygen; cryogenic propellants (e.g., liquid oxygen or liquid hydrogen [H_2]) where the fuel and oxidizer are maintained at very low temperatures; hypergolic propellants (e.g., hydrazine [fuel] and nitrogen tetroxide [oxidizer]) where mixing the fuel and oxidizer ignites the engine without requiring an external ignition source; or solid propellant (e.g., polybutadiene matrix, acrylonitrile oxidizer and powdered aluminum). Solid rocket motors can also be used as external motors to supplement the thrust of the first stage of an interceptor. Some propellants such as hydrogen peroxide can be used in concentrated form as a monopropellant or in conjunction with other propellants.

Interceptor Technology

As mentioned above there are two major kinetic energy technologies employed by interceptors, hit-to-kill and directed blast fragmentation.

Hit-To-Kill

Hit-to-kill technology relies on high closing speeds of an interceptor to collide with and destroy the threat missile. The interceptor uses kinetic energy, that is, the force of the collision, to destroy the threat warhead. Most of the BMDS elements, e.g., GMD, Aegis BMD, THAAD, and PAC-3, use this interceptor technology. Exhibit 2-10 shows an example of an interceptor launch.

Exhibit 2-10. Interceptor Launch

Directed Blast Fragmentation

Directed blast fragmentation technology involves the interceptor approaching the threat ballistic missile and exploding close to it, thereby disrupting the path of the threat missile and possibly destroying it. The interceptor does not actually collide with the threat ballistic missile. A directed blast fragmentation kill vehicle explodes near the threat missile and distributes its fragments over a large area to create a kill zone around the path of

the threat missile. As the quickly moving threat missile enters the kill zone it collides with the fragments, which alter its path and potentially destroy the threat missile altogether. Arrow and PATRIOT systems currently include this technology.

Lasers

Laser use directed energy to destroy threat ballistic missiles. High mobility and speed-of-light intercept are key aspects of directed energy weapons. The ABL element currently uses this laser technology.

A megawatt class chemical HEL is being developed as part of the BMDS boost phase defense system. HEL devices are laser systems that use high speed flowing gas or large amounts of electrical power, or combinations of the two, to produce directed beams of energy. The chemical oxygen iodine laser (COIL) is one of three lasers under consideration to be integrated into the BMDS. The COIL operates by creating chemical reactions between chlorine gas and a mixture of hydrogen peroxide and alkali metal hydroxides. The chemical reactions produce a form of oxygen (singlet delta) that is used to transfer the energy to atoms of iodine. The iodine, in turn, releases this energy as light, which is then focused by mirrors and lenses into a laser beam. The COIL has four primary parts: oxygen generator, gain generator (or resonator), pressure recovery system, and storage tanks that hold all the chemicals needed to operate the laser. Directed energy from the laser weapon would heat the threat missile body canister causing overpressure and/or stress fracture, which would destroy the missile. The HEL could be mounted on an aircraft and flown at high altitudes to detect, track, and destroy threat missiles in the boost phase.

2.2.1.2 Weapons Basing Platforms

There are four primary weapons basing platforms considered in this PEIS: land, air, sea, and space. Some of the interceptor and laser technologies could be based on more than one type of platform while others might be based on only a single platform. The basing platform for a weapon would affect the impact that the weapon has on the environment. The weapons basing platform may also affect the phase of flight in which the weapon can intercept a threat missile. The description and analysis of the support equipment and infrastructure associated with the fixed weapons basing platforms (e.g., missile silos, launch pads, sled tracks) and the mobile weapons basing platforms (e.g., mobile launchers, aircraft, ships, satellites) are presented under Support Assets, equipment and infrastructure, respectively.

Land-based Platforms

Land platforms would be either fixed or mobile. The fixed land platforms would include missile silos, launch pads, and launch stools from which interceptor missiles could be launched. Sled tracks and engine test stands could be used to test motors for interceptors or conduct GTs of directed energy weapons. Mobile land platforms currently include mobile launchers mounted on trucks or trains and moved into the desired location. The following BMDS weapons would use land platforms: KEI, GBI, THAAD, PAC-3, AWS and MEADS.

Air-based Platforms

Air platforms would include balloons and aircraft of various types and sizes. The ABL is currently the only proposed BMDS element with a weapon using an air platform, i.e., the HEL.

Sea-based Platforms

Sea platforms would be either fixed or mobile. The fixed platforms would include man-made islands or vessels anchored to the sea floor. The mobile platforms would be either self-propelled or moved or towed via a tug vessel. These could include ships, submarines, and other sea-faring vessels (e.g., platforms not anchored to the sea floor). The KEI and the Standard Missile (SM) are currently the proposed BMDS weapons using a sea platform.

Space-based Platforms

Space platforms would carry sensors and/or weapons and would be carried into space by launch vehicles. Once released by the launch vehicle, the space platform would maneuver into the appropriate orbit around the Earth using on-board propulsion systems. The platforms could be maneuvered into several different types of orbits including Geosynchronous Earth Orbit (GEO), which allows the platform to remain positioned over one location on the Earth, and Low Earth Orbit (LEO), which allows the platform to be positioned over various parts of the Earth at different times. The space platforms would maintain their orbit by using on-board propulsion systems for the duration of their useful life. The proposed KEI and space-based lasers are types of weapons that could use a space platform.

2.2.2 Sensors

Sensors are the tools that function as the "eyes and ears" of the BMDS. BMDS sensors would provide the relevant incoming data for threat ballistic missiles. Detailed sensor descriptions can be found in Appendix E. The data from these sensors would travel

through the communication systems of the proposed BMDS to Command and Control (C2) where a decision would be made to employ a defensive weapon such as launching an interceptor. The BMDS sensors would provide the information needed to determine the origin and path of a threat missile to support coordinated and effective decision-making against the threat. Additionally, these sensors would provide data on the effectiveness of the defense employed, that is, whether the threat has been negated.

BMDS sensors would be developed or enhanced to acquire, record, and process data on threat missiles and interceptor missiles; detect and track threat missiles; direct interceptor missiles or other defenses (e.g., lasers); and assess whether a threat missile has been destroyed. These sensors (i.e., radar, infrared, optical, and laser) would include signal-processing subcomponents, which receive raw data and use hardware and software to process these data to determine the threat missile's location, direction, velocity, and altitude. This and other relevant information would then be integrated into planning and controlling intercept engagements through the C2BMC component of the BMDS. For the purposes of this PEIS, the analysis of sensor systems will focus on the emissions power and range of the sensor categories to determine which sensors have the most potential for environmental impacts.

The three general categories of sensors considered in this PEIS include

- **Weapon/Element Sensors**. These sensors are part of the individual weapons and elements and allow them to operate independently from the overall BMDS. An example of this type of sensor is the PATRIOT radar. Although weapon/element sensors are designed for independent utility, they would also have the capability to function as an integrated part of the BMDS both in a testing or deployment scenario. For example, the ABL sensors could serve as forward sensors for the BMDS and could be used during testing to provide target information to midcourse and terminal phase weapon components. Discussion of sensors in this category is found under the individual Weapon/Element discussions in Appendices D and E of this PEIS.

- **BMDS Mission Sensors.** These are radar and optical sensors that are not part of an element but would provide data essential to the functional capabilities of the BMDS. These independent sensors would provide information for missile warning, early interceptor commit, in-flight target updates, and target object maps through the BMDS C2BMC architecture to the BMDS and its components. The MDA would include these existing sensors in testing activities either as part of the BMDS architecture or to evaluate a test of other parts of the BMDS architecture. For example, an EWR, such as the Position and Velocity Extraction Phased Array Warning System (PAVE PAWS), could be used to identify an ICBM target and provide cueing information to a midcourse sensor, such as SBX, to test sensor interoperability.

- **Test Range Telemetry Sensors.** These are the sensor systems used to acquire, record, and process data on targets and interceptor missiles during testing on a test range. They detect and track targets, observe defensive weapons, and assess whether a target has been destroyed. They also support range safety activities by providing test operators with information on whether the range is clear of non-test participants (i.e., recreational boats, private aircraft, etc.) and the test is proceeding within planned parameters. These sensors are not part of the actual BMDS, but are considered part of the BMDS Test Bed. Test range telemetry sensors include fixed sensors at test range facilities and mobile sensors at test range facilities or on ships or aircraft. Mobile sensor capabilities add flexibility for testing while minimizing fixed infrastructure investment. The description and analysis of such sensors are presented under Support Assets - Test Assets.

Sensors can also be described in terms of the technologies employed in the various sensor types as discussed below.

2.2.2.1 Sensor Technologies

The technologies used by the existing and proposed BMDS sensors fit into four basic categories, ***radar***, ***infrared***, ***optical***, and ***laser***, based on the frequency or electromagnetic (EM) energy spectrum used by the sensor.

Radar Technology

Radar, which stands for **RA**dio **D**etection **A**nd **R**anging, typically is an active sensor that emits radio frequency energy toward an object and measures the energy of radio waves reflected from the object. Radars are currently based in land and sea operating environments. Most modern radars operate in a frequency range of about 300 megahertz (MHz) to 30 gigahertz (GHz), which corresponds to a wavelength range of one meter to one centimeter. The time delay in the return signal or echo allows the determination of distance to the object and the change in the frequency of the echo through the Doppler Effect allows the determination of the object's speed. The Doppler Effect is the shift in frequency resulting from relative motion of an object in relation to, in this case, the radar. Most current radars are mono-static because the transmitter and receiver are collocated. There are also radars with multiple transmitters and multiple receivers in different locations that are called bi-static and multi-static radars based on the number of transmitters and receivers. Exhibit 2-11 summarizes the wavelengths and frequencies of radar bands.

Exhibit 2-11. Radar Band Designations

Band	Wavelength Ranges	Frequency Ranges
High Frequency	100-10 meters (328-33 feet)	3-30 MHz
Very High Frequency	10-1 meters (33-3.3 feet)	30-300 MHz
Ultra High Frequency	1 meter-10 centimeters (3.3 feet-4 inches)	300-3,000 MHz
L band	30-15 centimeters (12-6 inches)	1-2 GHz
C band	15-7.5 centimeters (6-3 inches)	2-4 GHz
S band	7.5-3.75 centimeters (3-1.5 inches)	4-8 GHz
X band	3.75-2.50 centimeters (1.5-1 inches)	8-12 GHz
Ku band	2.5-1.67 centimeters (1-0.66 inches)	12-18 GHz
K band	1.67-1.11 centimeters (0.66-0.44 inches)	18-27 GHz
Ka band	1.11-0.75 centimeters (0.44-0.30 inches)	27-40 GHz
W band	3 millimeters (0.12 inches)	95 GHz
Mm band	-	110-300 GHz

Infrared Technology

Exhibit 2-12. DSP Satellite

Infrared sensors detect the heat energy or infrared radiation from an object. Infrared electromagnetic radiation (EMR) has wavelengths longer than the red end of visible light and shorter than microwaves (roughly between one and 100 microns). The Defense Support Program (DSP) satellite, as shown in Exhibit 2-12, is an example of a space-based infrared sensor (SBIRS) that can detect the heat signature or plume from the launch of a ballistic missile.

Optical Technology

Optical sensors operate in the **visible** range and are generally passive sensors that detect objects or missiles by collecting light energy or radiation emitted from the target in wavelengths visible to the human eye. Specifically, the human eye perceives this radiation as colors ranging from red (longer wavelengths, approximately 700 nanometers) to violet (shorter wavelengths, approximately 400 nanometers). The planned Space Tracking and Surveillance System (STSS) satellites, for example, would have both infrared and optical sensors.

Laser Technology

Laser is an acronym for **L**ight **A**mplification by **S**timulated **E**mission of **R**adiation. Laser sensors use laser energy of various energy levels and frequencies (ultraviolet, visible) to illuminate an object to detect the object's motion. Like radar, a laser-based sensor is an active sensor that sends out laser energy toward an object and then receives a return echo from the object. The time delay in the return signal or echo allows the determination of distance to the object and the change in the frequency of the echo through the Doppler Effect allows the determination of the object's speed. The ABL aircraft uses passive infrared sensors to detect, and laser sensors to illuminate and track threat ballistic missiles.

2.2.2.2 Sensor Operating Environments

The operating environments of the existing and proposed BMDS sensors can be considered in four general categories. **Land-based** sensors may be fixed, located in or on a building, or mobile, located on a vehicle or trailer. **Air-based** sensors are located on platforms that can travel through the air such as airplanes, balloons, and airships. **Sea-based** sensors are located on platforms that travel on water (e.g., ships or a floating platform) or are fixed in water (e.g., a man-made island or platform like an oil platform that is fixed to the seafloor). **Space-based** sensors are located on satellites, which travel in circular or elliptical orbits around the Earth. These satellites can be in several different types of orbits including GEO, which is an orbit at approximately 36,000 kilometers (21,700 miles), synchronized with the Earth's rotation, and LEO, which is an orbit at an altitude of approximately 160 to 1,600 kilometers (100 to 1,000 miles). Weather, communications, and some military satellites, such as DSP satellites, typically use GEO orbits.

The following exhibit outlines many of the current and proposed sensors that would or could be developed to provide the BMDS with the required sensor functionality. Exhibit 2-13 includes the proposed operating environment or current proposed location for each of the sensor types.

Exhibit 2-13. Proposed Sensors, Roles and Operating Environments

Sensor	Primary Function	Operating Environment
ABL Infrared Search and Track (IRST)	Infrared Sensor	Airborne
ABL-Active Ranging System (ARS)	Laser Sensor	Airborne
ABL-Beacon Illuminator Laser (BILL)	Laser Sensor	Airborne
ABL-Track Illuminator Laser (TILL)	Laser Sensor	Airborne
Advanced Research Project Agency Lincoln C-band Observable Radar (ALCOR)	Tracking Radar	Fixed land-based
Aegis SPY-1 Radar	Fire Control Radar	Mobile sea-based
Arrow Fire Control Radar	Warning and Fire Control Radar	Mobile land-based
Forward-Based X-Band Radar Transportable (FBX-T)	Tracking and Discrimination Radar	Mobile land-based
Ballistic Missile Early Warning System (BMEWS)	EWR	Fixed land-based
COBRA DANE	EWR	Fixed land-based
U.S. Naval Ship Observation Island	Radar	Mobile sea-based observation platform
DSP	Infrared Sensor	Space-based
Ground Based Radar Prototype (GBR-P)	Fire Control Radar	Fixed land-based
Innovative Science and Technology Experimentation Facility (ISTEF)	Optical and laser sensors	Land-based sensor experimentation facility
ISTEF Mobile Sensors	Optical and laser sensors	Mobile sensor systems based at ISTEF
Maui Space Surveillance System (MSSS) [a.k.a. AMOS]	Optical Infrared Sensor	Fixed land-based
MEADS Surveillance Radar	Warning and Fire Control Radar	Mobile land-based

Exhibit 2-13. Proposed Sensors, Roles and Operating Environments

Sensor	Primary Function	Operating Environment
PATRIOT Radar	Warning and Fire Control Radar	Mobile land-based
PAVE PAWS Radar	Early Warning Radar	Fixed land-based
SBX	Tracking and Discrimination Radar	Mobile, sea-based platform
STSS	Infrared Sensor	Space-based
SBIRS-High	Infrared Sensor	Space-based
THAAD Radar	Warning and Fire Control Radar	Mobile land-based
Transportable System Radar (TPS-X)	Instrumentation Test Bed Radar	Mobile land-based

2.2.3 Command and Control, Battle Management, and Communications (C2BMC)

C2BMC would provide the rules, tools, displays and connectivity to enable the proposed BMDS to engage threat missiles. C2BMC would be the overall integrator of the BMDS. C2BMC would consist of electronic equipment and software that enable military commanders to receive and process information, make decisions, and communicate those decisions regarding the engagement of threat missiles (see Exhibit 2-14). This would include computer workstations installed in existing infrastructure at certain locations, and may include new fiber optic cable, radios, and satellite communications.

Exhibit 2-14. Typical Command Center

C2BMC would be designed and built to provide war fighters with the capability to effectively plan and execute the MDA's mission. C2BMC would integrate and expand existing capabilities that provide the flexibility to exploit a wide range of tactics, techniques and procedures and BM options. The goal of C2BMC is to achieve seamlessness in a layered defense through coordinated C2 and integrated fire control.

Specifically, C2BMC would receive, process, and display tracking and status data from multiple elements, components and sensors so that local commanders at various locations would have the same integrated operating picture and could make coordinated decisions about deploying weapons. This would allow the central command structure to use the most effective weapons to engage threat ballistic missiles in all flight phases.

The BMDS C2BMC includes three primary parts, Command and Control (C2), Battle Management (BM), and Communications that would operate in an integrated fashion across all BMDS components.

- **C2** would provide a flexible, integrated architecture to plan, direct, control and monitor BMDS activities. C2 would provide decision-aid applications that integrate information and recommendations for defensive options in near real-time to develop the operational war fighting aids required for formulating and implementing informed decisions and reduce decision cycles. This would permit quick redirection and reallocation of assets based on rapidly changing situations and threats. C2 also would integrate the Unified Commands, North Atlantic Treaty Organization and other allies, friends, and other external systems to which C2 would connect.

- **BM** would control the launching or firing of missiles and integrate the kill chain functions (surveillance, detect/track/classify, engage and assess) across the layered defenses (boost, midcourse and terminal). Initially, BM would provide the means for executing preplanned responses by integrating available information to provide near real-time tasking and status. As the BMDS evolves, BM would evolve to provide the user with increased automation, capability, and ability to integrate information from increasingly diverse resources. Advancements in BM are intended to further increase the battle space with continued improvements in tracking and discrimination information, sensor netting, operability with coalition partners, near real time intelligence, battlefield learning and dynamic planning, and integrated BM execution using disparate sensors and firing units.

- **Communications** would allow all BMDS components to exchange data and network with BMDS assets. The goal of BMDS communications is to provide robust networks that manage the dissemination of the information necessary to perform the C2 and BM objectives. The communications networks would seamlessly connect BMDS components and link them with other applicable DoD and non-DoD networks and assets as required. The network infrastructure would make optimal use of existing data and information conduits and protocols.

The long-term development of the C2BMC would begin with planning and monitoring the autonomous operation of elements with stand-alone capability and expand to the centralized and integrated control of the BMDS. Currently, each BMDS element, such as THAAD, PAC-3, or ABL operates or is designed to operate as an autonomous unit, each

with stand-alone capability and with its own BM, C2 and communications system (i.e., element-specific BMC3). C2BMC would fuse the data of these BMC3 components by integrating communications to provide a more robust picture of the operational arena. Individual element weapon system component descriptions can be found in Appendix D.

For example, a BMDS element like the PAC-3 has an internal or organic BMC3 component that transfers needed data from its data-gathering sensors (e.g., satellites and radars) to its local military commander. Using the information, the local military commander can make a BM decision to launch a weapon at the incoming threat ballistic missile. The BMDS C2BMC would capture and display tracking and status data from multiple existing and proposed weapon systems' BMC3 systems and sensors so that local commanders at various locations would have the same integrated operating picture and could make coordinated decisions about deploying weapons. C2BMC would include existing and new land-, sea-, air- and space-based C2BMC systems.

In an integrated BMDS, C2BMC would ensure interoperability with other BMDS components in reacting to the threat. For example, if an ABL sensor identifies the presence of an incoming ballistic missile, the information would be transmitted to the BMDS C2BMC. In coordination with other incoming information across the BMDS, a decision could be made that an Aegis cruiser launching a Standard Missile-3 (SM-3) would be the most effective element to engage and negate the threat missile. The commander of the cruiser would have real-time knowledge of the decision to quickly launch an SM-3 interceptor against the threat missile.

The MDA plans to improve the internal BMC3 capabilities of each BMDS element and to develop and continually upgrade the overall BMDS C2BMC. New or additional sensors and communications nodes would be incorporated, as well as new target discrimination algorithms, as they are developed.

Various U.S. command centers would eventually house a C2BMC node. A node is a set of equipment and processes that performs the communications functions at the end of the data links that interconnect those elements, which are resident on the networks. C2BMC nodes are located at geographically dispersed facilities and receive and display tracking and status data from multiple BMDS components so that local commanders can make coordinated decisions about deploying weapons. Each node consists of electronic equipment, software, computer workstations, radios, fiber optic cables, and communication devices. Nodes at various locations integrate and communicate data using this hardware and software to support C2 and BM activities. Each of these nodes would receive and display the same data to local commanders so that they can make coordinated decisions about weapons use.

2.2.4 Support Assets

Support assets are comprised of auxiliary equipment, infrastructure, and test assets that facilitate BMDS operations. Some of the support equipment (e.g., tracking stations and data processing systems) and infrastructure (e.g., test ranges and launch facilities), and all test assets comprise the BMDS Test Bed. They enable BMDS components to operate at maximum effectiveness over an extended useful life. Assets that support BMDS components include mobile equipment, such as cooling systems, power generators, and operator control units as well as fixed infrastructure such as docks and shipyards, launch facilities, airports and air stations, and communication facilities. Support assets as described above will be analyzed separately from their associated component.

Test assets used for component and system testing and deployment purposes include mobile equipment, infrastructure, and other equipment (e.g., target missiles). Although these test assets are not components of the BMDS, they are critical to its effective development and demonstration. Typical test assets would include test range facilities, targets, countermeasure devices, test sensors, optical and infrared cameras, computers, and observation vehicles (e.g., aircraft, ship, trucks, etc.). These test assets are designed to simulate a threat missile in a realistic environment and to assess and enhance the performance of BMDS components in negating those threats.

2.2.4.1 Equipment

The MDA would use a variety of equipment to support the functioning of BMDS components. Interceptors may require generators, fuel tanks, lightning protection, and security surveillance systems. Some weapons elements have mobile launchers such as the THAAD's modified M-1120 Heavy Expanded Mobility Tactical Truck-Load Handling System Palletized Load System launcher, as presented in Section 2.2.1.2, Weapons Basing Platforms. Support equipment for the ABL includes chemical transfer and recovery receptacles to capture laser chemicals from the aircraft and cooling systems for the laser. Existing aerospace ground equipment at each air base would be utilized where possible to support the ABL aircraft, as needed (e.g., generator to run the aircraft's electrical system). Sensors require antenna equipment units, electronic equipment units, cooling equipment units, and prime power units. These units are housed on separate trailers interconnected with power and signal cabling, as required.

Mobile assets also may include trucks, telemetry vans, personnel trailers, rail cars, aircraft, ships, ocean tugs or barges. For each testing event or deployment location, the MDA would use these vehicles to transport the component, test assets (i.e., targets, sensors, telemetry, etc.), and personnel to the site.

2.2.4.2 Infrastructure

Infrastructure that supports the functions of BMDS components includes docks, shipyards, rocket and missile launch facilities, airports/air stations, and communication facilities. These facilities serve as a base of operation from which components begin their missions and return for maintenance, repair, or storage. The MDA would use existing facilities to the extent possible to minimize the need for new construction. Specific types of facilities that would support the BMDS are discussed below.

Docks and Navy Bases

Sea-based components (e.g., Aegis BMD configured ships, mobile launch platforms, transportable telemetry stations) would operate from existing U.S. Navy bases near deployment locations, and possibly other Federal, state and local assets if required. Sea-based platforms for sensors (e.g., SBX platform, mobile launch platform) would be launched from a base and transported to deployed locations at sea. Periodically, the platform would return to primary support base for repairs, maintenance, or upgrades. The operation of the SBX platform has been considered in the GMD ETR EIS.

Launch Facilities and Ranges

The MDA would use existing launch facilities like those at Cape Canaveral Air Station, the National Aeronautics and Space Administration's (NASA's) Kennedy Space Center and Wallops Flight Facility, Vandenberg AFB and the Kodiak Launch Complex (KLC) to launch test and defensive operational assets into orbit. As appropriate, test launch activities could also take place from these facilities. The MDA activities at these launch facilities would be the same as those for other non-BMDS launches at a DoD or NASA launch facility. Other test ranges, e.g., White Sands Missile Range (WSMR), Pacific Missile Range Facility (PMRF), Ronald Reagan Ballistic Missile Defense Test Site (RTS), etc., would continue to be used for various test events involving interceptor and/or target launches. These ranges and facilities comprise the BMDS Test Bed.

Airports and Air Stations

The MDA would use existing military airports and air stations as a base for operation of airborne components including airborne sensors and weapons. The suite of MDA airborne sensors would be installed and operated in modified civilian and military aircraft, which have the capability to land and takeoff from any large airport. The aircraft would use both contractor and military facilities. Hangars and maintenance facilities at the home air base would be used to maintain the airborne sensors.

Communication Facilities

The MDA would use the existing communication facilities (e.g., C2BMC nodes, transmission towers, and repeaters) located at existing military service installations, launch facilities, ranges, air stations, and on other federally owned or leased property. BMDS development, testing, and integration might require the modification of existing communication facilities, or the construction of new communication facilities within or outside such areas.

2.2.4.3 Test Assets

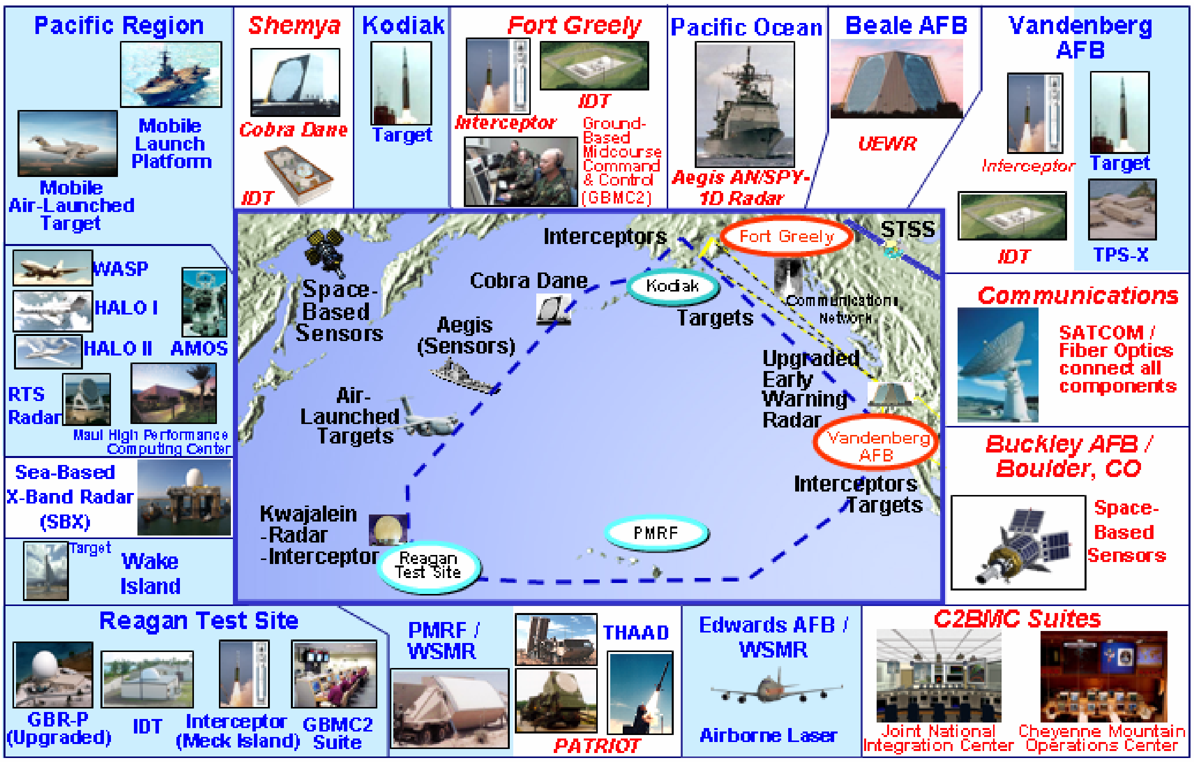
Test assets are not components of the BMDS but are support assets critical to its effective development and testing. Typical test assets would include test range facilities that make up the BMDS Test Bed, sensors used only for test purposes, targets, countermeasure devices, and warhead simulants. Test assets are designed to enhance the BMDS by simulating a threat missile in a realistic environment and to assess the performance of BMDS components in negating those simulated threats. The development and use of countermeasures and simulants in the BMDS test program are part of MDA's Measurement Program as identified in Section 2.2.5. In analyzing impacts of implementing the BMDS in Section 4, countermeasures and simulants will be considered as part of the test portion of the acquisition life cycle as part of Support Assets – Test Assets.

Test Bed

The BMDS Test Bed encompasses the infrastructure and environment where testing takes place. It provides a collection of integrated development hardware, software, prototypes, and surrogates, as well as supporting test infrastructure (e.g., instrumentation, safety/telemetry systems, and launch facilities) configured to support realistic development and testing of the BMDS. Exhibit 2-15 depicts key components of the BMDS Test Bed. The infrastructure primarily provides GT facilities, range and range instrumentation, and mobile sensors. The existing BMDS Test Bed infrastructure components that support testing as a secondary purpose (e.g., COBRA DANE and the EWR National Energy Technology Laboratory) are described under their respective component (e.g., sensors). A major focus is to develop infrastructure that enables realistic testing by permitting realistic geometries for sensor viewing and interceptor engagements. The Test Bed includes test locations already being used, such as GT sites, or already developed, such as the GMD ETR in the Pacific Ocean. In addition, testing could occur from existing operationally deployed sites in compliance with all applicable Federal, state, and local regulations. The MDA may also develop test beds in other areas such as the Atlantic Ocean, Gulf of Mexico, or outside the continental U.S. to support testing of BMDS components in those areas. In 2012, MDA contemplates the development of a space-based test bed; however, the concept is too speculative to be

analyzed in this PEIS. The BMDS Test Bed provides opportunities to use several target and interceptor missile trajectories that encompass a range of missile threats. Test Bed activities help wargames prove out doctrine; operational concepts; tactics, techniques, and procedures; and concept of operations (CONOPS) in militarily relevant environments.

Exhibit 2-15. BMDS Limited Defensive Capability Block 2004 Test Bed



BMDS Test Bed Components Providing *Limited Defensive Capability are Shown in Red Italicized Font.*

MDA's limited defensive capability (LDC) includes the BMDS components having a limited, combat capability to defeat adversary threats. The LDC allows Combatant Commanders use of the BMDS, to refine operational tactics, techniques, and procedures and exercise command control functions while maintaining a missile defense test and development program. For more discussion of BMDS fielding and deployment see Sections 2.3.3 and 2.3.1.1, respectively.

Test Sensors

The technology and operating environments for test range telemetry sensors, radars, and light detection and ranging (lidar) sensors are the same as the technology and operating environments of the element sensors and the BMDS mission sensors described in Section 2.2.2. During test planning, the MDA would identify the appropriate sensor that would provide the necessary location and functions to support achievement of the test

objectives. BMDS mission sensors and test range telemetry sensors as well as radars and lidars would be returned to their normal non-BMDS mission after each test event. Test sensors would be analyzed for environmental impacts in the same manner as described for weapons and mission sensors. Exhibit 2-16 provides information on representative test sensors that are available for use in BMDS testing. These sensors are further described in Appendix E.

Exhibit 2-16. Summary of Representative Test Sensors

Sensors	Type	Test Telemetry	Operating Environment
Advanced Missile Signature Center	Optical sensors	X	Fixed land-based facility
Air Force Research Laboratory (AFRL) Mobile Atmospheric Pollutant Mapper Carbon Dioxide (CO_2) Lidar	Test Lidar		Mobile land-based
AFRL Ka-Band Radar	Test Radar		Mobile land-based
AFRL Mobile Lidar Trailer	Test Lidar		Mobile land-based
ALTAIR	Test Radar	X	Fixed land-based
AN/FPQ-10 Upgraded	Test Radar	X	Fixed land-based
AN/FPS-16	Test Radar	X	Fixed land-based
AN/MPS-25 AN/MPS-25 (upgraded)	Test Radar	X	Fixed land-based
AN/MPS-36	Test Radar	X	Mobile land-based
AN/MPS-39	Test Radar	X	Mobile land-based
AN-TPQ-18	Test Radar	X	Fixed land-based
ATR-500C	Tracking Radar	X	Fixed land-based
FPQ-14	Test Radar	X	Fixed land-based
High Accuracy Instrumentation Radar (HAIR)	Range Radar	X	Fixed land-based
High Altitude Observatory (HALO)	Infrared/ Optical Sensor	X	Mobile air-based platform
Homing All-the-Way-Killer X-Band Doppler Radar	Test Radar		Fixed land-based
Midcourse Space Experiment (MSX)	Observatory sensors	X	Space-based
Millimeter Wave Radar	Test Radar	X	Fixed land-based
MK-74	Test Radar	X	Mobile land-based

Exhibit 2-16. Summary of Representative Test Sensors

Sensors	Type	Test Telemetry	Operating Environment
Recording Automatic Digital Optical Tracker	Optical sensor	X	Fixed land-based
Tracking and Discrimination Experiment Radar	Test Radar	X	Fixed land-based
W-Band Tornado Radar	Test Radar		Mobile land-based
Widebody Airborne Sensor Platform (WASP)	Tracking Radar	X	Mobile air-based platform

Targets

Because targets are test assets, they would not be deployed in the BMDS in the same way as weapons or sensors. Target missiles would be used to provide realistic threat challenges for testing new and evolving interceptor missile and sensor components that would comprise the BMDS. Target missiles would be used to validate the capabilities of the BMDS missile defense sensors and weapons. Target missiles typically mimic a possible threat, both in physical size and performance characteristics. A wide variety of target missiles would be used to support the development and test requirements of various BMDS elements, and validate their design and operational effectiveness. Targets would be used to test how well the BMDS can track the threat missile, communicate the threat to the appropriate ground command, and employ an interceptor to engage the threat. Targets can be launched from air, ground and sea platforms. The availability of multiple platform options allows the MDA to develop challenging and creative test scenarios, including salvos (i.e., simultaneous discharge of weapons), and also provides numerous viable options for test events to ensure safe testing.

Exhibit 2-17 shows the relative sizes and ranges of some typical test targets. Test targets are sometimes referred to by the names of their stages or motors.

Exhibit 2-17. Typical Test Targets

A typical target missile consists of one or more boosters and a target test object. Boosters are the rocket motors that sequentially activate to launch the missile. Target test objects are the parts of target missiles that are designed to represent threat warheads or reentry vehicles. (The term reentry vehicle is used in conjunction with threat missile.) A target test object typically separates from its booster(s); but some targets are non-separating.

Separating targets can be single-stage, meaning that they have one motor that initiates flight, or multiple-stage, with two or more motors that fire sequentially. Multiple stages allow a target missile to fly at higher velocities and altitudes, and for longer distances. Once the motor on a single-stage target has used all of its propellant, the spent stage may be jettisoned or released from the test object and falls back to Earth, often breaking up into small pieces before it reaches the surface of the designated test area. For targets with multiple stages, the first stage operates similar to a single stage target. However, after the first stage uses all of its propellant, that stage is jettisoned and the second stage or motor is ignited and the target continues on its path. This sequence of events is repeated until all of the stages have been used. Exhibit 2-18 lists the representative targets and boosters used by the MDA. There also are additional targets under development based on the Navy Trident-1 motors and alternative liquid fuel concepts.

Exhibit 2-18. Representative MDA Targets and Boosters

Targets	Aries
	Foreign Material Acquisition
	Hera
	Lance
	Liquid Propellant Target
	Long Range Air Launch Target
	Medium Range Target
	Minuteman II
	PATRIOT as a Target
	Peacekeeper Target Missile
	Short Range Air Launch Target
	Storm
	Strategic Target System
	Strypi
	Trident Target Missile, C-4
	Vandal
Boosters	Antares
	Black Brant
	Castor IVB
	Lynx
	Malemute
	M55, M56, M57
	Orbus
	SR-19
	Talos
	Terrier
	Trident C4 First Stage, Second Stage, Third Stage

The target test object would separate from the booster at a designated point in its flight. Test objects typically consist of steel or aluminum housing assembly, thermal sensors, guidance and control electronics, radio transmitters and receivers, a power supply (which may include lithium or nickel-cadmium batteries), and a Flight Termination System (FTS).

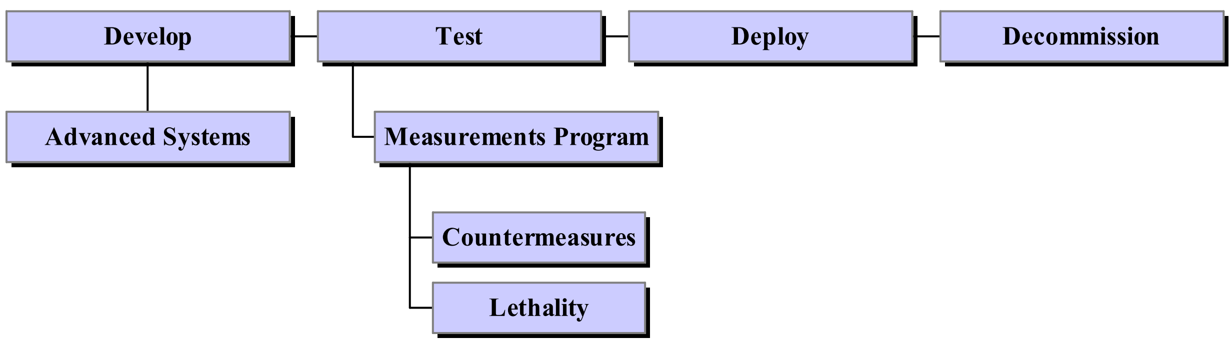
Target test objects may use countermeasures or decoys to imitate threat missiles as well as simulants to imitate the characteristics of the payload of a threat missile. Countermeasures are devices that accompany the target missile during its flight and attempt to confuse the sensors and C2 systems, making a successful intercept more difficult. Simulants are substances that mimic the significant characteristics of chemical, nuclear, biological or explosive payloads carried by threat missiles. Countermeasures

and simulants are also used to support the development and testing of the BMDS. They are programs within MDA's Measurements Program and are discussed further in Section 2.2.5.

2.2.5 MDA's Programs

The MDA implements several programs that support various aspects of the implementation of the BMDS, notably including the Advanced Systems program, the Measurements Program, and the International Program. As shown in Exhibit 2-19, the Advanced Systems program supports the development portion of the BMDS acquisition life cycle. The Measurements Program includes the Countermeasures and Corporate Lethality Programs, which support the test portion of the BMDS acquisition life cycle.

Exhibit 2-19. MDA Programs Supporting the BMDS Acquisition Life Cycle



Given the worldwide implications of ballistic missile defense, MDA also has an active International Program that includes the participation of several international partners in a variety of BMDS-related development and test activities.

2.2.5.1 Advanced Systems

The Advanced Systems program addresses research and technology improvements to enhance, supplement, or replace various building blocks or capabilities as the proposed BMDS evolves over time. Some technology improvements are currently proposed; others will evolve in the future (i.e., cannot be identified at present). Examples of current Advanced Systems projects include Project Hercules, the High Altitude Airship (HAA) and Multiple Kill Vehicles. Additional discussion of the MDA's Advanced Systems program can be found in Appendix F.

2.2.5.2 Measurements Program

To assess and characterize specific aspects of BMDS components' performance during testing, the MDA implements a Measurements Program. The program is designed to provide critical data and analyses that fulfill BMDS requirements identified and

prioritized by the Measurements Program Assessment Team. Measurements tests would be incorporated in individual component tests as well as integrated tests in laboratories, GTs of components, and during flight tests.

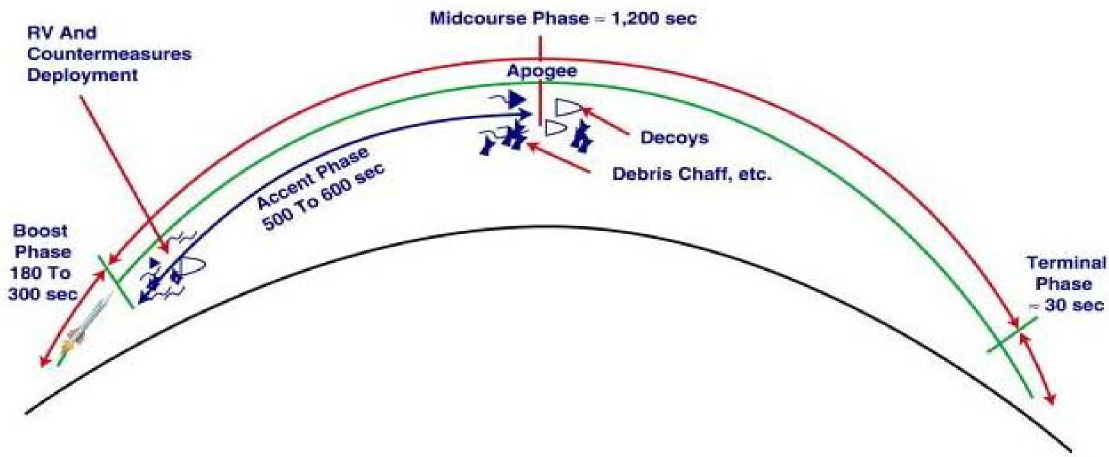
The Measurements Program would conduct critical measurements tests to collect data for all components to support system engineering assessments/performance verifications and ground effects analysis, and to characterize potential or actual countermeasures. At this time, “measurements” includes counter-countermeasures characterization, lethality, kill assessment, discrimination data, phenomenology measurements (the observation, description and explanation of the visible appearance of a test), and other critical measurements. The Measurements Program includes the Critical Measurements and Countermeasures Program (CM/CM), Countermeasure and Counter-countermeasure Program, and the Corporate Lethality Program. The CM/CM program is designed to address discrimination phenomenology, countermeasure performance, BMDS performance degradation, and potential mitigation options. The Countermeasure and Counter-countermeasure program attempts to characterize countermeasure signatures and to assess counter-countermeasure efficacy. Lethality, or the ability of the BMDS to prevent a ballistic missile threat from producing lethal effects, relies on kill assessment and other data gathered by BMDS component sensors and test sensors. Data are gathered through the Optical Data Analysis, Radar Data Analysis, and Radar Data Exploitation Programs.

Countermeasures

Countermeasures are designed to increase the probability that the reentry vehicle from a threat missile reaches its intended target. BMDS testing would include the use of robust countermeasures designed to mimic those that could be used on potential threat missiles. By testing the capabilities of U.S. interceptors against realistic targets including countermeasures the ability of the U.S. to respond to an enemy missile attack would be greatly enhanced. The specific signature and nature of the countermeasures that would be used as part of the BMDS testing activities are classified. Therefore, the discussion in this document on the potential impacts of countermeasures that would be used in BMDS testing is generic in nature.

There are two primary types of countermeasures, penetration aids or penaids and inherent countermeasures. Penaids are items that are added to the missile to increase the chance of the missile reaching its intended target. Penaids could be housed in the target reentry vehicle separation module. One penaid technique is for an offensive missile to carry, in addition to the actual target reentry vehicle, several decoy target reentry vehicles. These decoys, shown in Exhibit 2-20, when released, appear to be actual warheads. Inherent countermeasures are elements of normal operations of missiles that make it harder for interceptors to identify and destroy the target missile. This would include the separation

Exhibit 2-20. Deployment of Countermeasures during Flight Phases



of the reentry vehicle from the booster, which decreases the size of the portion of the missile to be tracked and destroyed by the interceptor.

There are various basic categories of countermeasures that could be used by MDA in characterization and in testing the BMDS. These include simulation, anti-simulation, traffic maskers/obscurants, aim point denial, and maneuver. Each uses different methods to add potential threat characteristics to targets used in the Measurements Program or in other BMDS testing.

Simulation countermeasures deploy various materials to confuse sensors and prevent them from correctly identifying the reentry vehicle. These countermeasures would primarily be fabricated from graphite, stainless steel, and tungsten. Anti-simulation countermeasures attempt to disguise the reentry vehicle by making the reentry vehicle look to the sensors like something other than a reentry vehicle. Traffic countermeasures deploy many items at once; this could include using multiple reentry vehicles or multiple countermeasures to confuse sensors. Maskers or obscurants are materials or objects that move in flight along with the reentry vehicle to confuse the sensors and prevent them from correctly identifying the reentry vehicle. Aim point denial is the ability to confuse the sensors from identifying the point on the reentry vehicle that should be hit to prevent the reentry vehicle from reaching its intended target. Maneuver countermeasures include the ability of reentry vehicles to change trajectory as they enter the atmosphere thus preventing the interceptor from predicting the path of the reentry vehicle. Other countermeasures are designed to increase the probability that the reentry vehicle reaches its intended target.

Lethality

Lethality is a measure of the ability of the BMDS to prevent a threat ballistic missile from producing lethal effects. Preventing a threat missile from completing its mission could entail the use of kinetic energy (hit-to-kill and blast fragmenting weapons) or directed energy (laser) to intercept and neutralize the target. Adequate lethality of the interceptor missile ensures the destruction of incoming enemy warheads to minimize potential threats. Lethality effects are described as either hard kills or soft kills. A hard kill occurs when damage done directly to the threat at the point of intercept results in the payload's immediate destruction. A soft kill occurs when damage done to the threat either causes the threat's destruction due to the effects of atmospheric drag/reentry on surviving payloads or prevents the payload from reaching its intended target. Lethality analyses begin at the moment of impact and continue through to interaction of the target pieces and any surviving payload contents with the Earth. The MDA is developing criteria to evaluate the lethality capability of BMDS technology against various threats. Potential enemy threats could include bulk High Explosive, High Explosive-laden submunitions, nuclear, biological, chemical, and bulk chemical payloads carried on tactical ballistic missiles.

Lethality studies include the monitoring and analysis of threat payload destruction and dispersion during intercepts of test threat targets. Although limited testing is done on actual lethal agents under controlled laboratory conditions, most of the testing relies on a number of payload simulants that, while chemically and biologically neutral, mimic the significant qualities, such as dispersion, weight, and viscosity of a toxic or hazardous substance for test purposes. Testing would require the use of existing simulants and may require the use of newly developed ones.

Because the countermeasures and lethality programs support BMDS testing, they will be considered along with other test assets (i.e., test bed, test sensors, and targets) in the analysis of impacts in Section 4.

2.2.5.3 International Programs

The MDA's mission is to develop and field an integrated BMDS capable of providing a layered defense for the U.S. homeland, deployed forces, allies and friends against ballistic missiles of all ranges in all phases of flight. To this end, the MDA supports a variety of international programs and invites international participation in its own programs. For example, the Arrow System Improvement Program is a joint undertaking with Israel, which will include technical cooperation to improve the performance of the AWS and a cooperative test and evaluation program to validate the improved performance.

2.3 BMDS Life Cycle Activities

This section describes the activities that occur during each phase of the acquisition life cycle (i.e., development, testing, deployment, and decommissioning) for BMDS components.

2.3.1 Development of BMDS Components

The MDA would develop the necessary components of the BMDS using an evolutionary spiral development process described in Section 2.1.3.2. The MDA would use existing infrastructure and components, when feasible, and would add emerging and new technologies as they become available. The components would be combined into specific configurations to achieve desired functional capabilities. Development activities would contribute to the evolution of the BMDS design as existing component configurations are altered or new configurations are created in response to evolving functional capabilities. During the development of new and modified components, environmental and occupational safety and health procedures would be developed. As outlined in Exhibit 1-3, development of BMDS components includes activities such as planning, budgeting, research and development, systems engineering, site preparation and construction, maintenance and sustainment, manufacture and initial testing of prototype test articles, and conduct of tabletop exercises.

2.3.1.1 Weapons

Weapons include interceptors and lasers as described in Section 2.2.1. Development of weapons components would build on existing infrastructure and capabilities of the BMDS elements. Research and development activities for weapons that could potentially have environmental consequences include research and development activities such as developing and testing propellant formulations for new rocket motors, developing or selecting casing materials, and developing and testing subscale rocket motors. System engineering tests such as hardware-in-the-loop tests would involve using an actual kill vehicle, intercept sensor unit, or directed energy component electrically connected to a computer system that simulates the functions of the other components of an interceptor. Repair, maintenance, and sustainment of weapons systems would include checks to ensure that system technology is still viable and cleaning, which may involve the use of solvents. Manufacturing and initial testing of prototype weapons technology may require static-fire testing of boosters or the firing of the HEL and may also involve the use of a sled (i.e., a carrier vehicle that is designed to move along a section of rail at speeds approaching missile flight velocities) to test boosters or to provide target opportunities. Tabletop exercises would allow developers to plan the interaction of a weapons system's internal technology, as well as its interaction with other components. These activities would occur at both contractor and government facilities and would include environmental and operational tests under simulated field conditions and computer simulations.

2.3.1.2 Sensors

The development of sensors would build on existing sensors and infrastructure including the current development efforts for radars such as X-band, S-band, L-band, C-band, and infrared, optical, and laser sensors as described in Section 2.2.2 and Appendix E. The types of activities involved in developing sensor components would include planning, budgeting, research and development, systems engineering, repair, maintenance, and sustainment, manufacture and initial testing of prototype test articles, and conduct of tabletop exercises. Research and development of mobile systems might include transportability demonstrations, possibly using aircraft and ground transport. All other development activities for sensors would be similar to those required for weapons. For example, systems engineering tests would include environmental and operational tests under simulated field conditions and computer simulations. These activities would occur at both contractor and government facilities and would include environmental and operational tests under simulated field conditions and computer simulations.

2.3.1.3 C2BMC

C2BMC includes the hardware and software and related infrastructure that connects and integrates the BMDS as described in Section 2.2.3. Development occurs in close conjunction with the weapons and sensors components described above and would utilize the existing assets and infrastructure when feasible. Development activities would include planning, budgeting, research and development, systems engineering, repair, maintenance, and sustainment, manufacture and initial testing of prototype test articles, and tabletop exercises.

For purposes of this PEIS, analysis of the environmental impacts associated with the installation, construction, or manufacture of C2BMC equipment and facilities will be considered, including computer terminals and displays (hardware) and the necessary computer programs (software) to provide BM and C2 functionality. C2BMC improvements may include simple software upgrades, updated computers, new facilities, buried communications cable, and, possibly, construction of new centers. Additionally, the analysis includes communications assets such as military and commercial satellite communications (COMSATCOM) terminals and antennas, radio communications terminals and antennas, and above- and below-ground communications cables (e.g., fiber optic and copper). A satellite communication system would provide satellite communications among C2BMC nodes. The satellite system would consist of satellite terminals, equipment buildings housing communications enclosures, backup power and dish antennae. The In-Flight Interceptor Communication System Data Terminal (IDT) is a part of the C2BMC and provides an in-flight communications link between nodes and interceptors. If a new satellite system or IDT system would be required, impacts would result from building construction and launch of the satellites. Fiber optic cable uses light pulses to transmit information along fiber optic lines. Where new fiber optic cable is

required, cable may be installed on either side of existing rights-of-way (e.g., normal roads or railroad tracks). Typically, fiber optic cable would be buried to a depth of approximately one meter (three feet) from the surface.

2.3.1.4 Support Assets

Support assets as described in Section 2.2.4 are the mobile and fixed auxiliary equipment, vehicles, and facilities that are needed to support and facilitate the operation and on-going evolution of BMDS components and testing of the system. Development of support assets including test assets for the BMDS would be closely coordinated with the development of the weapons, sensors, and C2BMC components. Planning for future support assets is critical to ensuring that they are acquired in time to meet the needs of upcoming BMDS components.

BMDS Test Bed

The BMDS Test Bed would encompass the infrastructure and environment where testing takes place. Development of the Test Bed would focus on planning for and acquiring infrastructure that enables realistic testing by permitting realistic geometries for sensor viewing and interceptor engagements. The proposed Test Bed includes test locations already being used, such as GT sites, or already developed, such as the GMD ETR in the Pacific Ocean. The MDA may also expand the Test Bed to include other areas in the Atlantic Ocean, Gulf of Mexico, outside the continental U.S., and ultimately a space-based test bed to support robust and realistic testing of BMDS components in those areas. The MDA would use existing sensors and launch facilities along the Atlantic and Gulf coasts to evaluate phenomenology and interoperability of sensors. Exhibit 2-21 lists the facilities in the Atlantic or Gulf of Mexico that are currently used for MDA activities or may be used in the future and could be eventually included in the BMDS Test Bed. Some facilities are independent, and others fall under the jurisdiction of a Range. Those installations that are under the jurisdiction of a Range are presented beneath that Range. The MDA would use launches from NASA and U.S. Air Force (USAF) facilities as targets of opportunity to reduce the number of MDA launches required.

Exhibit 2-21. Facilities Available in the Atlantic or Gulf of Mexico

Facility	Location
Gulf Test Range/Eglin AFB	Florida
Cape San Blas	Florida
Santa Rosa Island	Florida
Mobile Sea-Based Platform	Broad Ocean Area (BOA)
Eastern Test Range/Cape Canaveral Air Force Station	Florida
Mobile Sea-Based Platform	BOA
NASA Kennedy Space Center	Florida
Tyndall AFB	Florida
Space Port Florida (Florida Space Authority)	Florida
ISTEF – Merritt Island	Florida
Mobile Sea-Based Platform	
Cape Cod Air Station	Massachusetts
Hanscom AFB	Massachusetts
Lincoln Space Surveillance Complex	Massachusetts
Redstone Arsenal	Alabama
Naval Air Test Center Patuxent River	Maryland
Aberdeen Proving Ground	Maryland
Ocean City Municipal Airport	Maryland
NASA Wallops Flight Facility	Virginia
Newport News Municipal Airport	Virginia
GBI Development and Integration Laboratory	Alabama
Stennis Space Center	Mississippi

Test Sensors

Development of test sensors, as described in Section 2.3.1.2, would include activities similar to those that would occur in the development of the BMDS mission sensors and BMDS element sensors.

Targets

Preparing targets for flight test events would involve designing, prototyping, developing, procuring, certifying and qualifying them. Targets would be developed in response to the needs of BMDS and element testing requirements. To reduce costs, several targets would use retired components from other programs, including the U.S. Army Pershing II program, U.S. Navy Polaris program, Trident-1 (C-4), and U.S. Air Force Minuteman II program, as well as some Foreign Material Acquisitions. This practice would not only reduce the amount of raw material used but would also limit the amount of production

needed to develop realistic threat targets. These retired components may be used in their original configuration, or may undergo minor reconfiguration, depending on the specifications of the test. Every target system currently built meets unique test requirements; therefore, production of target systems is item-by-item and not in quantities. MDA is developing a family of targets to provide a standard target missile to support short-, medium-, and long-range test requirements.

Advanced target applications in progress include short- and long-range air-launched targets and liquid fuel boosters, as well as a multi-mode medium-range target. MDA is developing a family of targets that provides standard target missiles to support short, medium and long range test requirements. Mobile launch/basing platforms are being considered, along with the development and future procurement of advanced countermeasures and payloads.

Countermeasures

Development of countermeasures would involve detailed planning for test events, and identifying test objectives, appropriate countermeasures and counter-countermeasures, and acquiring any necessary materials.

Two types of defensive measures would be used to oppose countermeasures. The first would be improving sensor technology to more completely discriminate between the reentry vehicle and any deployed countermeasures. During the development of flight tests involving countermeasures, appropriate sensors would be selected and scheduled to participate in the test event. The second defensive measure would be improving interceptor technology to increase the chance that the interceptor can correctly identify and destroy the reentry vehicle. Development activities would include modeling and simulation as well as ground testing to characterize physical properties of countermeasures and predict behavior during flight tests.

Lethality

Assessing lethality involves the use of chemical or biological simulants that, while chemically and biologically neutral, mimic the significant qualities of a toxic or hazardous substance for test purposes. Development of simulants would involve research and planning, identification of neutral or inert substances with the required physical properties for specific tests, and in some cases manufacturing significant quantities of the simulant.

2.3.2 Testing of the BMDS

Testing is a critical aspect of the BMDS life cycle and under the spiral development process would occur simultaneously with the development and deployment periods of the life cycle acquisition process. Testing allows for the life cycle of all BMDS components to be closely correlated so that efforts in particular areas of the BMDS may be truncated or canceled if the results are unsatisfactory or where the development effort should be shifted to another integrated BMDS element to permit acceleration.

Testing will require several basic activities as outlined by component in Exhibit 1-3. Weapons, sensors and C2BMC components would be manufactured specifically for a test event, and appropriate site preparation and construction would be conducted at the test location. Infrastructure in the Test Bed would be constructed and prepared and components transported to the site, as necessary, and interceptors and targets would be assembled and fueled. Where necessary, sensors would be assembled before activation. The appropriate occupational safety and health procedures and appropriate training would be developed and followed for these activities.

Testing occurs at the component (Section 2.3.2.1), element (Section 2.3.2.2), and system (Section 2.3.2.3) levels. The goal of BMDS testing is to demonstrate integrated and effective functioning during increasingly complex and realistic engagement sequences. An engagement sequence is a unique combination of detect-control-engage functions performed by BMDS components (such as sensors, weapons and C2BMC) used to engage a threat ballistic missile. The C2, BM, and fire control functions enable the engagement sequence. Individual component and element tests are required to demonstrate the functionality of BMDS technology. Element tests evaluate the ability of component configurations to work together. These tests are the beginning of integrated BMDS tests. Some components may not be designed to be a part of an element (e.g., upgraded EWR). In those cases, the component would move from component level testing directly into System Integration Tests. See Section 2.3.2.3 for description and discussion of System Integration Tests. Integration testing is the activity that occurs above and beyond that which is required during the demonstration phase for each component or element. Integration system testing assesses the ability of BMDS components to work as a unit and to meet the required functional capabilities of the system.

2.3.2.1 Component Tests

The following describe the test activities that would be performed for each of the components in the proposed BMDS.

- **Weapons.** Weapons testing activities for interceptors would include the static firing of rocket boosters, sled tests, and isolated flight tests to confirm booster function (for single and multiple stages). For lasers, testing would demonstrate laser function and individual operation of laser-related components**.**

- **Sensors.** The primary objective of sensor component testing would be to evaluate performance in detecting and tracking surrogate threat ballistic missiles. Tests would utilize targets of opportunity, that is, launches supporting other research programs. Performance would be evaluated by comparing observed and predicted performance on target detectability, measurement accuracy, and tracking accuracy. In general, test objects representative of the reentry vehicles and countermeasures would be required to support both development and operational test and evaluation activities.

- **C2BMC.** The C2BMC must receive, fuse, and display tracking and status data from multiple components and coordinate firing/launches and intercepts. Testing would involve modeling and simulations to assess hardware and software capabilities and to demonstrate interoperability prior to participation in test events. C2BMC components would be tested in concert with their corresponding weapons and sensors components.

- **Support Assets.** Testing of support assets (including test assets) is discussed separately following the discussion of System Integration Tests. This includes the discussion of MDA Measurements Program countermeasures and simulants testing as part of test assets.

Testing of individual components has been largely addressed in existing NEPA analyses as listed in Appendix C, Related Documentation.

2.3.2.2 Element Tests

Element tests are required to evaluate the ability of component configurations to work together. Descriptions of element test activities and status by block are described in Appendix D, Descriptions of Proposed BMDS Elements. Testing of individual elements and support asset components have been largely addressed in existing NEPA analyses as described in Appendix C, Related Documentation.

2.3.2.3 System Integration Tests

The MDA is proposing to perform integration test activities on existing and planned components such as sensors, weapons, and C2BMC equipment. Integration testing of BMDS components provides system characterization, verification and assessment. Integration testing assesses the ability of BMDS components to work as a unit and to meet the required functional capabilities. Ongoing demonstration activities are required to assess a component’s continuing utility within the system. System Integration Tests

would be used to demonstrate BMDS performance. System Integration Tests rely on a foundation of individual component tests and culminate in SIFTs. This section describes typical flight test activities, the approach and descriptions of integration test events, and the contribution of the MDA's BMDS Measurements Programs to the assessment of technological capabilities.

Typical Flight Test

A typical weapons flight test would involve the use of a simulated airborne target, the use of a drone, or the launch of a target missile, the launch of an interceptor missile or the firing of a laser, and the intercept of the simulated threat missile target. Flight-testing also would provide measurements on the effectiveness against countermeasures and the lethality of the kill vehicle.

The MDA would deploy personnel and assets to the test locations to prepare for the flight mission (FM), conduct the flight test, and refurbish the test sites to pretest conditions, if applicable. Prior to a test event, the target launch site(s) would generally be occupied for approximately three months before a scheduled launch and about two weeks after a launch. A typical three-month launch cycle ramp-up would include 25 people during the first month, 25 to 75 people during the second month, and 100 to 150 people during the third month. Dual target launches would include approximately 25 people during the first month, 75 to 100 people during the second month, and 150 to 175 people during the third month. After a launch, approximately 50 personnel would immediately depart, and the remaining personnel would depart after launch site refurbishment.

The MDA would launch target missiles in a manner that represents relevant adversarial capability and provides the components with opportunities to practice their function in a realistic situation. The duration of a typical test flight would vary based on the component(s) that are involved and the flight phase where intercepts would occur. Flights with a planned intercept in the boost phase would last up to five minutes. Flights with intercepts in the midcourse phase would last from about five to 20 minutes. Flights with intercepts in the terminal phase would last up to approximately 20 to 30 minutes. Airspace surveillance procedures, which would be implemented to ensure range safety, would last as little as 45 minutes or longer if the test is delayed.

After launch, the target missile would slowly gain speed in the first few seconds of flight, and then rapidly accelerate out of sight and earshot. One minute into flight, a typical target missile would be at an altitude of approximately 16 to 19 kilometers (10 to 12 miles). The first stage would burn out, and in the case of a separating target, would fall within the predicted booster impact area. The second and third stages (if used) would perform in similar manners, and the target missile would climb out of the atmosphere and into space. The reentry vehicle or non-separating target would reenter the atmosphere and decelerate until it is intercepted or until the mission is completed.

To intercept the target missile, the tracking radar would acquire and track the target while the interceptor C2 system computes the best time to launch the interceptor missile. The interceptor missile would then be launched. Approximately one minute into flight, the interceptor would be at an altitude of about 50 kilometers (31 miles) and approximately 65 to 80 kilometers (40 to 50 miles) down range. (The altitude and distance down range will depend greatly on the trajectory and type of missile.) The first stage would burn out and fall within the predicted booster impact area. The second and third stages (if used) would ignite, and the interceptor would continue along its intended path. After burnout, the second and third stages would fall into their designated impact areas. After the final stage burnout, the interceptor, or deployed kill vehicle, would continue its flight until the target is intercepted. If the intercept were unsuccessful, the interceptor or kill vehicle would be destroyed by mission control or would be allowed to return to Earth. All booster stages and interceptors would be programmed to land in predetermined and verified clear areas. Intercept altitudes could vary from approximately 100 to more than 250 kilometers (62 to more than 150 miles). (The altitude and distance down range would depend greatly on the trajectory and type of missile.)

System Integration Testing Approach

The BMDS Test Program provides for a cohesive testing program of the interoperability of all Block architecture components and elements. System Integration Tests would involve interaction between and assessment of ground-, sea-, air- and, in some cases, space-based test assets. As the BMDS evolves, System Integration Test scenarios would become more complex and realistic to evaluate the integration of a higher number of working elements and components. More realistic scenarios would introduce an increasing number of targets. In addition, critical measurements programs may start as early as the components level and go up through integration system tests.

MDA's Responsible Test Organization provides the single point of responsibility, authority, and accountability for the BMD System Integration Testing. The Responsible Test Organization manages the test bed infrastructure and collaborates with the elements and components to develop system characterization and coordinate System Integration Tests. The Combined Test Force (CTF) is the execution arm of the Responsible Test Organization that develops long range and detailed plans, provisions, executes, acquires data from and analyzes the Campaigns.

The System Integration Test planning process is driven by goals that are laid out in guidance and technical objective documents. These objectives indicate the functional capabilities that need to be met by BMDS technologies. From the overview documents, a series of more detailed planning documents outline the details of test objectives, test requirements, and scenarios for System Integration Testing. These documents would be developed and revised regularly. Combinations of components that can meet functional capabilities would be identified. Dedicated component and element tests would be

synchronized to create a System Integration Test. Supporting components are identified to maximize the amount of data that can be gathered during a System Integration Test. System Integration Tests include modeling, simulation, and analysis, missile defense wargames, missile defense integration exercises (MDIEs), integrated GTs, and one or more SIFTs. System Integration Tests may also be performed for targets of opportunity. SIFTs are the culminating test event combining all prior test activities. These testing events evaluate component and integrated system performance and readiness.

A brief description of each type of System Integration Tests is provided in Exhibit 2-22.

Exhibit 2-22. Description of System Integration Tests

Test	Description
Modeling, Simulation, and Analysis	Modeling, simulation, and analysis are used during test planning, rehearsal, prediction of test outcomes, and post-flight assessment to verify and update models.
Integrated Missile Defense Wargames	Integrated missile defense wargames are table-top or computer simulations of military operations involving two or more opposing forces, using rules, data, and procedures designed to depict an actual or assumed real-life situation.
MDIEs	MDIEs are designed to characterize interoperability and how BMDS software components communicate prior to actual test flights.
Integrated GTs	GTs are tests used to collect data for BMDS components characterization and assessment and do not include booster function flight tests. GTs aim to reproduce the existing state of BMDS architecture, typically components scheduled for upcoming flight tests, to prepare for those flight tests and to assess component performance. For the purposes of this PEIS GTs do not include activities associated with components but rather have been focused on System Integration Testing.
SIFTs	SIFTs are conducted to verify the integration of select BMDS components. These tests generally include a target launch, sensors tracking the target, laser activation or an interceptor launch, and sensors to determine whether the target was destroyed. The number of sensors, weapons, and targets used in a SIFT can be adjusted to create the desired test scenario.

Modeling, Simulation, and Analysis

Modeling, simulation, and analysis are used to provide insight on test design and potential range constraints. Models are used prior to tests to rehearse and predict the test outcomes. In the post-flight phase, models are used to assess and analyze test results. Use of models allows the actual tests to be more successful, for example, by ensuring that a test does not violate a range constraint. Modeling also allows for "overlaying," a technique to predict and evaluate a component's response to a test exercise in which it did not participate. Analysis of post-flight data also allows the validation, verification and update of models.

Integrated Missile Defense Wargames

Integrated missile defense wargames are simulations, by whatever means, of military operations involving two or more opposing forces, using rules, data, and procedures designed to depict an actual or assumed real-life situation. They are designed to gain insight into how human decision-making affects the use of BMDS components. The MDA would use wargames to confirm the effectiveness of its CONOPS. The MDA could conduct multiple system-wide wargames per year. Prior to a wargame event, the MDA would determine the necessary data requirements. Integrated missile defense wargames are tabletop and computer simulation based and do not have a field component. Actual participants attend each wargame and the results allow insight into the information exchange between the BMDS elements and components, coordination during engagement, inventory expenditures, and improvement to CONOPS. For example, prior to a Campaign, an integrated missile defense wargame would be conducted with players and observers to examine BM schemes, shot doctrines, and other operations procedures.

Missile Defense Integration Exercises (MDIEs)

MDIEs are exercises designed to characterize how BMDS software components are communicating. The MDA has developed a Missile Defense System Exerciser to support interoperability testing. Its primary purpose is to characterize the interoperability among the BMDS elements, ensuring the ability to operate as a single system. Throughout the development of the BMDS, there are frequent updates to software, particularly the C2BMC software. The Missile Defense System Exerciser allows for tests of MDA software and hardware. An MDIE would be conducted specifically to support block software integration prior to SIFTs. The MDA plans to conduct multiple MDIEs per year.

Integrated GTs

GTs are tests used to collect data for BMDS characterization and assessment, and do not include component testing activities and System Integration Tests. For purposes of this PEIS, static test firings of rocket boosters, sled tests, or booster function flight tests are considered component level GTs. Component tests have largely been addressed in existing NEPA analyses as identified in Appendix D. Those analyses that were incorporated by reference are included in Appendix C. The analysis of GT activities considered in this PEIS focuses on system integration GTs, which would provide an understanding of the BMDS component integration and assessment, as well as how each component responds in different situations. Such tests provide data on risk reduction for system flight tests and for scenario exploration where flight-testing is either impractical or impossible. System integration GTs aim to reproduce the current state of BMDS architecture, typically components scheduled for upcoming flight tests, to prepare for those flight tests and to assess component performance. The GT tool must include weapon and sensor representations to do system performance testing and must be connected to a test bed as well as other deployed systems.

System Integration Flight Tests (SIFTs)

SIFTs measure BMDS component interoperability and assessment of BMDS functional capabilities in each developmental Block. SIFTs are the culminating test event that relies on testing activities such as integrated missile defense wargames and MDIE test events discussed above. They involve interaction between and assessment of ground-, sea-, air-, and, in some cases, space-based components. Each of the SIFTs incorporates dedicated component and element tests scheduled to occur at the same time. For example, testing of a specific interceptor would be synchronized to occur with the dedicated test of separate radar. The MDA plans to conduct up to two SIFTs per year.

Additional test components could be included in a SIFT to support data collection and overlays. For example, during a dedicated test of GMD’s ability to track and intercept a threat missile, the Aegis SPY-1 radar could be used as a forward sensor to track threat missile trajectory and relay it to the GMD interceptor. Any number of extra sensors could be tested during the SIFT to confirm other sensors’ tracking data. Overlaying is a technique to predict and evaluate a component’s response to a test exercise in which it did not participate. For example, the response of a PAC-3 interceptor to a threat that a THAAD interceptor actually engaged can be modeled to generate additional data and predictions.

Planned System Integration Tests

The MDA has planned a series of System Integration Tests to evaluate the status of the BMDS and its components. Activities conducted during a System Integration Test

include the planning of integration tests, production of components and support and test assets, and implementation of actual flight tests.

Targets and Countermeasures activities for Block 2004 would include the development of full-up target systems to support BMDS and element testing; development of payload suites for CM/CM flight tests and target risk reduction flights; and the maintenance, surveillance, refurbishment and routine testing of existing Government Furnished Equipment boosters.

The MDA plans to conduct a series of additional System Integration Tests to test the BMDS capabilities in Block 2004 and beyond. System Integration Tests represent independent flight tests that leverage from existing element or component tests. Future block testing would be planned and developed to meet the needs of the BMDS at the time of testing. Therefore, details of these integrated test events are only conceptual at this time. The general objectives and investment priorities for future Blocks include testing and validation efforts with a focus on integrated flight tests, with added realism and more stressing threat countermeasures. The BMDS layered defense is envisioned to be developing a strong boost phase intercept capability.

This PEIS examines the range of System Integration Test events as planned and described above. However, of the System Integration Test events, the GTs and SIFTs represent the most realistic testing scenarios. GTs involve the simultaneous activation of multiple sensors and C2BMC components, which would coordinate the control and transfer of information between weapons. A SIFT combines a range of test activities into a single test event that may occur over several days. SIFTs are designed to be increasingly complex integration tests over time. GTs and SIFTs are the only System Integration Tests with a field component and thus have the broadest range of potential environmental consequences. The example SIFT scenario described below is designed to capture the range of environmental effects that could occur from increasingly complex integrated testing of the BMDS. This example is meant to show a representative SIFT that could be conducted as part of the Proposed Action; it is not meant to be inclusive or exclusive of testing possibilities or launch trajectories.

Generic SIFT

A generic example of a SIFT would comprise initial selection of a launch and intercept of a single threat missile. In general, targets and interceptors would be launched from sites in the Test Bed. As a threat missile was launched, specific sensors would be tasked with acquiring and tracking the boosting threat missile and passing cueing information through the C2BMC to other sensor and weapon components. As the threat missile enters its midcourse phase, tracking responsibilities might be transferred to another component designed for that phase of flight. Additional cueing information would be passed again through the C2BMC to interceptor components. The threat reentry vehicle would be

identified and an interceptor launched. Intercepts would occur over designated land areas and BOAs. Once the threat had been intercepted, the component would perform a hit assessment and notify C2BMC of the results.

For example, a representative SIFT could include the GMD element engaging an ICBM long range target in the boost phase, with Aegis BMD acquiring and tracking the target from another location and sending the data to GMD. At the same time, Aegis BMD could engage a different target in the midcourse phase, with ABL acquiring and tracking the target during the boost phase. THAAD could engage another target in the terminal phase, coordinating with PAC-3 to identify the reentry vehicle. Additional components and elements could participate, by using the event as a target of opportunity (TOO) to validate their system performance.

Using information gathered during the SIFT; overlay scenarios would be constructed for other interceptor components. These scenarios would provide the ability to assess the capacities and limitations of each component in intercepting the threat without additional flight tests. Simulation overlays would also serve as a risk reduction in the integration of the components into the BMDS.

Future System Integration Tests

As discussed previously, System Integration Tests are designed to measure BMDS component interoperability and to assess BMDS functional capabilities. As the BMDS evolves to meet emerging threats, System Integration Tests must reflect the increasing number of integrated components. System Integration Tests become more complex as those components occupy more geographically diverse locations. Modeling, simulation, and analysis; MDIE; and integrated missile defense wargames are virtual tests (modeling and computational analyses) or software compatibility and communication tests that would be conducted within existing laboratory or test facilities. GTs involve the simultaneous activation of multiple sensors and C2BMC components, which would coordinate the control and transfer of information between weapons. However, SIFTs could involve the launch of targets and firing or launch of interceptors in addition to the participation of multiple sensors and C2BMC components.

SIFT scenarios attempt to capture more realistic intercept parameters. For purposes of this analysis, two representative scenarios that could be used during SIFTs under Alternatives 1 and 2 were considered. These two scenarios involve similar activities (launches of targets, use of multiple sensors, and use of land-, sea-, air-, and for Alternative 2 space-based weapons); however, they differ in number of target launches and number of weapons used. Both SIFT scenarios may be used to support the proposed BMDS and are analyzed in this PEIS.

SIFT Scenario 1 represents the simplest SIFT and would include the launch of a single target and use of a single weapon component to intercept the target. This scenario would use multiple sensors and C2BMC components. Under SIFT Scenario 1, the launch of the target and the activation of a laser or launch of an interceptor may occur within the same biome or may involve multiple biomes. As BMDS capabilities are proven, a second SIFT Scenario (*SIFT Scenario 2*) is envisioned that would build upon SIFT Scenario 1.

SIFT Scenario 2 would include the launch of up to two targets. For each target launch, more than one weapon component would be able to engage or "take a shot" at the target. Dual-target or interceptor launches would occur within seconds or minutes of each other. As with SIFT Scenario 1, numerous sensor components also would acquire the target and relay tracking data. Under this test scenario, the two targets may be launched from one biome and the weapons may be activated or launched from the same or different biomes.

SIFT scenarios are confined by geographic as well as range constraints that limit the number or types of launches that can occur at a specific location based on infrastructure and allowable debris impact zones. Each facility has either physical limits or regulatory limits on the number of simultaneous launches that it can execute. Test objectives also would limit the types of targets, countermeasures and simulants used.

The MDA would conduct future SIFTs in the existing or an expanded Test Bed. The current Test Bed is based around the Pacific Ocean. However, additional test facilities along the Atlantic Ocean and Gulf of Mexico as well as components located outside the continental U.S. may also be used.

2.3.2.4 Role of Test Assets in Integrated Testing

The MDA would use test assets to enhance the BMDS by simulating a threat missile in a realistic environment. Specific target missiles would be configured to meet the objectives of a SIFT scenario. Test assets would also support integration testing by providing infrastructure needed to assess the performance of components and systems, e.g., non-BMDS test sensors and telemetry may be used to acquire, record, and process data on targets and interceptors during testing.

Test Bed

The BMDS Test Bed would provide opportunities to use several target and interceptor missile trajectories that encompass a range of missile threats. Test Bed activities would help wargames prove out doctrine; operational concepts; tactics, techniques, procedures; and CONOPS in militarily relevant environments. Components of the Test Bed provide

IDC.[30] The IDC is comprised of the technical capabilities (hardware and software) of the BMDS available for operations on September 30, 2004. After the Combatant Commander has completed the requisite planning and the operators have been trained, qualified and certified to effectively employ the IDC equipment, along with the supporting integrated logistics and training systems, the components will constitute IDO.

Test Sensors

The primary objective of test sensor testing is to evaluate performance in detecting and tracking surrogate threat ballistic missiles. Tests would use targets of opportunity (TOO) as well as BMDS targets. Performance would be evaluated by comparing observed and predicted performance of the test sensor's ability to detect the target, accurately measure and track the target, and discriminate the reentry vehicle from countermeasures. In general, test objects representative of the threat ballistic missiles, reentry vehicles, and countermeasures would be required to support both development and operational test and evaluation activities for test sensors.

Targets

Target missiles are tested individually in risk reduction flights, to demonstrate their flight capabilities and ensure their safe operation. They are also used to test the capability of sensors. In interceptor tests, targets are used to test the coordination of the sensors, interceptors and C2BMC in completing a successful intercept. In some instances, the objective of the test event is to track and destroy the target with the defensive interceptor. Targets are also involved in flight tests as TOO. Tests using TOO rely on launches supporting other programs. In this instance, another program would participate in a passive role in a flight test, perhaps testing the ability of its sensors to track the target and communicate its properties to the appropriate ground control.

Flight-testing would be performed to verify performance and to test the interceptor's ability to engage and destroy target missiles under realistic conditions. Certain tests would involve only the acquisition of the target missile by the interceptor's seeker/sensor, while in other tests the target missile would be destroyed. In all cases, safety analyses would be conducted to ensure human health and safety are maintained and to avoid or minimize the possibility that any debris would cause harm to environmentally sensitive resources. Typically, several flight tests are conducted within a given test program.

Targets are transferred to their test locations by air, barge, and/or over-the-road truck for system assembly and checkout. Some missile components may be shipped to an airfield near the launch site and transferred to the launch site by local truck. Once target missiles

[30] IDC refers to the sensors, C2BMC, and weapons from Block 04 that are available for limited, militarily useful capability by September 2004. The IDC will include early warning and tracking sensors based on land, at sea, and in space, C2, and GBIs for midcourse and terminal intercepts.

reach the test range and are assembled, an appropriate Explosive Safety Quantity Distance (ESQD) would be established and maintained around facilities where ordnance would be stored or handled. Target missile launch preparation at ground launch sites may include the following activities: construction and/or modification of facilities and infrastructure to support launch preparation and flight test activities; fueling of liquid targets; transportation, handling, and storage of target missile system components and assemblies; assembly and maintenance of target missile and support equipment; and checkout and testing of target missile system components and assemblies.

Activities associated with ground, air, and sea launched targets differ based on the launch platform. In general, target missile operations at the test site may include missile assembly and checkout, maintenance, final inspections, testing and checkout for the reentry vehicle, and placement of the target on the launch pad.

Ground Launch Targets

Land launches of target missiles would be accomplished from a launch pad, launch stool, silo, or runway. Missiles would be assembled and checked out and erected on the launch stool or the pad or transferred to a launch silo before a scheduled test launch. Unmanned aerial vehicles or drones could also be used as targets. Drones can use a variety of engines including turbojet engines and gasoline powered combustion engines. Each missile storage or processing facility would have an ESQD established around it. Before a launch, a Launch Hazard Area (LHA) would be established. The LHA is the area that could be affected by missile debris should an explosion occur on or just above the launch area or in the event that the missile's flight must be terminated on the pad or just shortly after liftoff. This LHA is cleared of all non-mission essential personnel during launch operations to ensure personnel are not exposed to missile launch hazards.

Air Launch Targets

Air launches of target missiles may include target drones as described above for ground launch targets. However, for purposes of this analysis a typical Air Launch Target missile would use solid propellant boosters. The rocket motors for Air Launch Targets would be shipped from U.S. Government or contractor facilities by truck or air. Other components, such as the target/pallet assembly, would be shipped as applicable. When the target arrives at the test location, the motors would be assembled and the FTS installed and integrated with other components. The target reentry vehicle would be attached to the booster; then the booster, pallet and sled assembly, and support equipment would be loaded onto the aircraft.

Air Launch Targets would be launched from specifically configured U.S. Air Force cargo aircraft. Various target missile configurations could be used depending on the range needed for the particular test. The integrated target/pallet assembly would be loaded into

the aircraft and flown to a predetermined drop point. The target/pallet assembly would be pulled from the aircraft by parachute and dropped to a level between approximately 6,096 and 7,620 meters (20,000 and 25,000 feet) above mean sea level (MSL). The target would separate from the pallet and then descend via parachutes to approximately 4,100 meters (13,450 feet) above MSL. At this altitude, the parachutes would release the target, and motor ignition would occur during free-fall. After firing, the boosters would drop into predetermined areas in the ocean. The target would then follow its flight path to interception or to splash down within a designated ocean impact area. The target would be fitted with an FTS to terminate the flight if unsafe conditions develop.

Sea Launch Targets

Sea launches of target missiles would be conducted using specially configured missiles and any one of a number of sea-based platforms. The Sea Launch Target missile would consist of solid or liquid propellant boosters. The liquid propellant boosters can be either pre-fueled or non-pre-fueled. Target missiles and support equipment would be transported from U.S. Government storage depots or contractor facilities in accordance with Department of Transportation (DOT) regulations. They would be placed in secure storage until assembly and launch preparation. Applicable safety regulations would be followed in the transport and handling of hazardous materials. An appropriate ESQD would be established and maintained around facilities where ordnance is stored or handled.

Countermeasures

In Block 2004, the MDA would conduct activities that would contribute to the use of countermeasures in future Blocks. Dedicated flight tests of CM/CM, CM/CM-1 and CM/CM-2, would be conducted to support Block 2006/2008 system definition. During Block 2006 work would continue to improve existing countermeasure capabilities and provide new capabilities including development of payload suites for CM/CM flight tests and target risk reduction flights. The work completed during Block 2008 would represent a major step in the BMDS evolution. As target development matures, capability-based targets and payload suites (to include new and more complex countermeasures) would be developed, tested, and integrated into the BMDS testing program. The technical details for Block 2010 are less defined than near-term Block efforts however, it is expected that progression on the development and use of increasingly realistic countermeasures would be incorporated into the BMDS testing activities.

Lethality

Lethality studies include the monitoring and analysis of threat payload destruction and dispersion resulting from intercepts of test threat missiles. Although limited testing is done on actual lethal or live agents under controlled conditions (i.e., in a certified

laboratory environment), the majority of testing relies on a number of payload "simulants." Testing would require the use of existing simulants and may require the use of newly developed simulants.

The MDA divides lethality into four areas of interest. The first is target response, which analyzes the actual ballistic missile intercept of a threat. The second is the formation of the debris cloud containing both pieces of the target and any payload surviving the intercept. The third looks at the atmospheric conditions for transport and dispersion of the debris cloud. Last, the lethality program examines where and how much of the debris, especially the payload, impacts the Earth.

Lethality tests include investigating the impact of the intercept of various threat payloads at various altitudes and speeds. This involves using a mix of laboratory experiments, field tests, flight tests of opportunity, models, and hydrocode simulations and computational analysis. One critical objective of lethality testing is to calculate weapons of mass destruction intercept effects and consequences. Intercepts would occur in the boost phase of target flight or in the endo- or exoatmosphere. Therefore, the altitude and speed of intercepts may affect the effectiveness of an intercept and fate and transport of threat payloads. Because the nature of an incoming threat payload is unknown, lethality testing would assist in establishing a methodology to allow warhead typing based on impact response.

Simulant payloads would be incorporated into targets already scheduled to participate in BMDS element and system flight tests. This "piggy-back" method of data collection allows for the observation of tests of opportunity and the gathering of post-engagement lethality information. Analysis would be done to determine the damage done to submunitions (for both high explosive and chemical payloads) from interceptor missile impact. Submunitions are individual containers in the target designed to distribute a threat payload to a wider area. Multi-wavelength sensors would be used to track and characterize the resulting intercept debris cloud and its eventual impact on the ground.

Testing would also include the study of lethality enhancers, which aim to increase the kill radius of an interceptor missile. Examples of lethality enhancers could include additional explosives or tungsten pellets that explode out of the interceptor upon impact. In some cases, the additional explosives are included in the interceptor missile's FTS. Data collected from these tests would be used to continue to refine existing core lethality models. These studies are currently being conducted at federally funded research development centers, academic institutions, and DoD facilities in the U.S. and abroad. Simulated bulk chemicals can be dispersed upon impact with the interceptor and/or by using an explosive device. Using an explosive charge in the payload can enhance the dispersion of the chemicals, and thereby reduce the concentration of the simulant before it reaches ground level. In the event of a missed intercept, a termination device may be used to disperse the chemicals.

In Block 2004, the MDA would focus on resolving lethality questions and concerns for bulk chemical targets with simulants while transitioning to a greater focus on validating physical phenomena with full-scale flight-test data. This would include activities such as collecting data and analyzing various chemical agents and their simulants. Experiments would investigate the in-situ negation and breakup of simulants with a focus on boost and terminal phase intercepts. Lethality tests in future Blocks have yet to be determined but would involve similar tests based on prior block experiences and individual component and integrated testing plans.

2.3.3 Deployment of the BMDS

The U.S. would incrementally expand the functional capabilities of the BMDS by deploying components and elements as testing demonstrates that they are sufficiently capable of defending against threat ballistic missiles. Generally, a component would be deployed after it has been sufficiently developed and tested to demonstrate that it is capable of operating successfully within an integrated BMDS and the associated safety and health procedures are developed and deemed adequate.

The DoD is planning to use Missile Defense Test Bed assets to defend the U.S. when it has been determined that they provide a militarily useful defensive capability. However, the MDA could deploy individual developmental assets on an emergency basis, may field elements in limited numbers should it be determined that the prototype or test article had the potential to provide a militarily useful and sustainable capability, or the asset could be deployed if directed in support of national interests.[31] Components deployed on an emergency basis would function as partially integrated components of the BMDS until the emergency situation ends.

Deployment involves a series of actions to prepare the component or element to function in its defensive position and maintain a state of readiness to address missile threats. Deployment would involve fielding and sustainment activities as described below.

Development activities include acquiring components and planning for possible transfer to military services. As the missile defense acquisition agency, the MDA would be responsible for the purchase of developmental components and engaging the military services and Combatant Commands regarding their uses and sustainment. DoD decides that a military service will engage in component production with procurement funds. The MDA, through its development contractors, could build or assemble the component and the associated support assets needed for operation in the field. The MDA would engage the operating Combatant Command and the military service in transition planning to address roles and responsibilities regarding timing, resourcing, and other requirements.

[31]On December 17, 2002, President Bush directed the fielding of IDO capabilities by 2004, which would provide limited protection to defend the U.S. against ballistic missile attack. In October 2004, MDA achieved LDC when certain BMDS test components could also be placed on alert and used in defensive operations.

The military service and MDA would agree in writing on roles and responsibilities regarding the fielding of the components to include the preparation of the deployment site, transport of the component to the deployment site, installation and test in a field environment, and staffing the deployment sites. Preparing the deployment site includes facilities acquisition and related logistics functions that might be required to support the component in its fielded state. DoD direction to transfer the component to a service would establish the functions performed by MDA, the military service, and the Combatant Command(s). In the absence of an agreed to transition plan, or a DoD transfer decision, the MDA would operate and maintain the component.

Sustainment includes various maintenance and operating activities, including maintaining components in a ready state by conducting routine maintenance, repairing damaged or defective parts, testing the component's readiness, and resupplying the component with necessary materials. Component upgrades and service life extensions, as well as training operation personnel, also are sustainment activities.

Future deployment of BMDS components would occur at times and places where the deployed component would provide the most useful defensive capability to counter existing or emerging threats. This could include sites outside the continental U.S. The following subsections discuss potential deployment actions associated with each aspect of the deployment process (acquiring, fielding, transfer, and sustainment) that are considered in this PEIS.

2.3.3.1 Fielding BMDS Components

The MDA or a military service would obtain components for deployment by purchasing the components and their parts, and assembling the parts either on site or in an assembly facility, by transferring unused units originally planned for testing, or by ordering additional units from the manufacturer. Generally, the components would be manufactured by the same contractor and assembled in the same facilities where the units were manufactured and assembled for the testing program. However, the MDA or a military service would acquire the components from other sources if the existing contracts expire and a subsequent contract is awarded to another successful offeror. This PEIS assumes that components continue to be built by the existing development contractors at the same facilities because predictions of contract changes are speculative. All manufacturing would be conducted at facilities that are subject to Federal, state, and local environmental regulations. Construction of new facilities would be subject to all applicable requirements of NEPA, EO 12114, and other relevant Federal, state, and local environmental laws and regulations, as appropriate.

Fielding would include construction of facilities, transportation and installation of equipment, and training with the integrated components of the proposed BMDS.

Deployed components would be fielded at a number of locations to provide an integrated and evolutionary BMDS. Additional capabilities would be added to expand the BMDS as the technology develops. Components would be fielded at locations where they provide a layered defense against all phases of missile flight. Boost phase defense components would be fielded where they can operate in close proximity to potential threat missile launch sites. Midcourse defense components would be fielded at locations near potential missile flight paths. Terminal defense components would be fielded near theaters of operation, near major U.S. cities and other potential targets, and on allied territory.

The MDA or a military service would field components as directed by the DoD to provide a BMDS to counter a wider range of threats. Fielding of components requires several actions to move personnel and materials to the fielding site, prepare the site, place the component at the site, and to activate the component. Exhibit 2-23 summarizes typical fielding activities for the potential platforms.

Exhibit 2-23. Typical Fielding Activities

Platforms	Components	Typical Fielding Activities
Fixed and Mobile Land-based	Weapons, Sensors, C2BMC, Support Assets	▪ Site layout and clearing ▪ Facility construction, operation and maintenance ▪ Utility construction (electric, water, sewer, fiber optics, etc.) ▪ Material transport (truck, rail, air, ship) ▪ Waste management ▪ Human services (lodging, eating, work space)
Fixed and Mobile Sea-based	Weapons, Sensors, C2BMC, Support Assets	▪ Facility (e.g., dock, port) construction, operation and maintenance ▪ Utility construction (electric, water, sewer, fiber optics, etc.) ▪ Material transport (truck, rail, air, ship) ▪ Waste management ▪ Human services (lodging, eating, work space)
Mobile Air-based	Weapons, Sensors, C2BMC, Support Assets	▪ Airport and support facility construction, operation and maintenance (e.g., chemical plant) ▪ Utility construction (electric, water, sewer, fiber optics, etc.) ▪ Material transport (truck, rail, air, ship) ▪ Waste management

Exhibit 2-23. Typical Fielding Activities

Platforms	Components	Typical Fielding Activities
		▪ Human services (lodging, eating, work space)
Mobile Space-based	Weapons, Sensors, C2BMC, On Ground Support Assets	▪ Weapon or sensor construction ▪ Material transport (truck, rail, air, ship) ▪ Rocket launch ▪ Support facility construction, operation, and maintenance

In conjunction with combatant commanders, the MDA is planning to activate test assets (e.g., missiles, launchers, sensors, and C2 components) to provide continuous or near continuous defense of the U.S. The ongoing activities in support of the IDO at Vandenberg AFB and Fort Greely are illustrative of the site preparation activities that would be performed by the MDA when a component is fielded. The IDO fielding activities, and future fielding activities, would use existing facilities and infrastructure to the extent possible to minimize new construction. Site preparation at the two locations includes

- Construction of new or modified launch facilities and silos;
- Installation of sensors, fire control center, and C2BMC facilities;
- Development of missile assembly and launch preparation facilities;
- Development of facilities to store liquid propellants (fuel and oxidizers) and hazardous wastes;
- Installation of communication cables in existing conduits or new trenches, sensor hardstands, and antennae;
- Upgrade of electric power lines, installation of backup generators, and upgrades to water and sewer hookups as needed;
- Modification of existing or construction of new buildings to provide storage, maintenance, administrative space, security facilities, and housing;
- Upgrade of existing roadways and parking facilities, and
- Installation of security equipment.

The DoD transferred the PAC-3 program and realigned the MEADS program from MDA to the Department of the Army on February 5, 2003. As part of that transfer and realignment, MDA retained the responsibility for further research, development, test and evaluation, target development, future Block capability flight-testing, and software improvements to improve and maintain interoperability with C2BMC. This PEIS assumes that the MDA would retain similar responsibilities during future transfers to the military services.

2.3.3.2 Sustainment of BMDS Components

Sustainment of BMDS components includes operation, maintenance and repair, upgrades and service life extensions. MDA would operate deployed components until they are transferred to a service. Operation would include the consumption of fuel and power and generation of wastes. MDA and/or contractor personnel would conduct routine maintenance and repair on deployed components prior to transfer to a service. After transfer to a service, sustainment of components would be the responsibility of the appropriate service. Routine maintenance would primarily occur at the fielding location unless safety or environmental constraints necessitated a change in location.

2.3.4 Planning for Decommissioning of the BMDS

Decommissioning would involve the planning for the final demilitarization and disposal of the BMDS components and support assets no longer needed for the BMDS or its testing program. Decommissioning occurs when components reach the end of their effective service life, when technological advances render them obsolete, or when changes to the threat environment render them unnecessary at a location. Demilitarization is the act of destroying a system's offensive and defensive capabilities to prevent the equipment from being used for its intended military purpose. Demilitarization of the components would be performed in accordance with the DoD Directive 4160.21-M, *Defense Reutilization and Disposal*; DoD Directive 4160.21-M-1, *Defense Demilitarization Manual*; procedures developed by MDA or the responsible military service; and applicable Federal, state, and local regulations and procedures.

Disposal is the process of redistributing, transferring, donating, selling, abandoning, destroying, or any other disposition of the property. Disposal of components would involve establishing the availability of disposal facilities and then shipping hardware and materials to the disposal site. Disposal of materials would then conform to DoD directives, Joint Service Regulations, and comply with all applicable Federal and state laws.

Decommissioning processes will vary for weapons, sensors, C2BMC, and support assets and will be performed by the appropriate DoD agent. The following list describes the decommissioning activities that would be performed for each of the components in the proposed BMDS.

- **Weapons.** Decommisioning of weapon components would involve transferring the equipment to other uses or demilitarization in accordance with the appropriate requirements.

- **Sensors.** If sensor equipment is only needed for testing purposes and would not be used in the BMDS architecture, decommissioning would involve returning the

equipment to the responsible military service. If the equipment would be used in the BMDS architecture, decommissioning of sensors would include recycling/reuse or disposal or unused and residual materials, in accordance with the appropriate requirements. Additionally, assets can be converted to another MDA use, transferred to a military service, or sold. Space-based sensors would be decommissioned by being abandoned in orbit, parked in higher orbit, deorbited, retrieved, or reprogrammed for alternate uses.

- **C2BMC.** As technology advances and BMDS needs evolve, upgrades of C2BMC hardware and software would likely be necessary. C2BMC equipment that is replaced would be decommissioned in accordance with appropriate requirements.

- **Support Assets.** Decommissioning of equipment, infrastructure, and test assets would involve continued or adaptive use by the DoD or other government agencies, or performance of any necessary decontamination activities in the event the fixed asset will no longer be used, followed by sale. In the event of decommissioning, utilities could be left in place if the potential to use them for future DoD or other purposes existed. Mobile test or support assets would be refurbished and transferred to an alternate use, demilitarized, or dismantled and disposed. In terms of MDA BMDS Programs, aspects of particular MDA programs could be decommissioned by transferring them to another government agency, selling them, removing and using specific parts (i.e., sensors), or storing them at a government airfield. Each individual program also may have particular decommissioning activities associated with it.

Decommissioning could involve complete termination of operations and disposal of the system or its replacement with a new or upgraded system. Individual components would be removed from test ranges and test facilities at the conclusion of the testing activities. Testing facilities could also be decommissioned when they are no longer needed for the BMDS testing program.

Prior to decommissioning components, the MDA would evaluate the components for continued use by other U.S. Government agencies (e.g., U.S. Customs, U.S. Department of the Treasury) or as candidates for Foreign Military Sales. Various adaptive reuses would be analyzed and implemented if appropriate. If no adaptive reuses were identified, the units would be demilitarized and disposed as excess to the needs of the Government.

2.4 Alternatives

This PEIS considers two alternative approaches to providing the layered integrated BMDS program described in sections 2.1, 2.2, and 2.3. MDA analysis of the threat environment (potential launch locations, missile flight paths, and target locations) concludes that an effective missile defense should include weapons components based on at least the land, sea, and air. The addition of a space-based weapons platform would

provide another layer of missile defense capability. Providing only one or two weapons platforms would either leave areas unprotected or reduce the opportunities to engage threat missiles.

2.4.1 Alternative 1 – Implement Proposed BMDS with Land-, Sea-, Air-based Weapons Platforms

In Alternative 1, the MDA would develop, test, deploy, and plan to decommission land-, sea- and air-based platforms for BMDS weapons components and related architecture and assets. The BMDS envisioned in Alternative 1 would include space-based sensors, but would not include space-based weapons.

This section describes components and associated activities that would occur during each stage of the acquisition life cycle (development, testing, deployment, and decommissioning) under Alternative 1. Individual components would be developed and tested to determine the adequacy for deployment, that is, military utility and ability to function in an integrated BMDS. In addition, the BMDS C2BMC architecture would be designed and tested to meet the needs of an integrated system. Components deemed capable of integrated BMDS activities would be deployed and decommissioned as needed.

2.4.1.1 Alternative 1 - Development

Weapons subcomponents such as boosters, kill vehicles, and lasers would be derived from the existing and proposed elements. Development of the BMDS components as described in Section 2.3.1 for Alternative 1 would involve the following weapons components based on land, sea, and air operating environments

- Land – GMD GBI; THAAD; PAC-3; AWS; MEADS; KEI
- Sea – Aegis BMD; KEI
- Air – ABL

Development of BMDS sensors would build on existing sensors and infrastructure on land, sea, air and space operating environments. The development of C2BMC and support assets would be closely linked with the development of other components. The C2BMC is designed to mold components into a complementary and synergistic system-of-systems. Ongoing development of BMDS components is required to meet evolving functional capabilities. The main types of development activities include planning, budgeting, research and development, systems engineering, maintenance and sustainment, manufacture and initial testing of prototype test articles, and conduct of tabletop exercises.

New technologies are continuously being considered by the MDA's Advanced Systems program and by Systems Engineering Directorate within the MDA in concert with the National Team. The technologies and programs underway are discussed in Appendix F.

2.4.1.2 Alternative 1 - Testing

Testing activities, as discussed in Section 2.3.2, comprises the majority of activities under Alternative 1. Testing of the BMDS components and elements provides system characterization, verification, and assessment. Systems integrated tests rest on a foundation of component and element level tests, which were described in previous environmental documentation. This PEIS analyzes System Integration Tests including Modeling, Simulation and Analysis, integrated missile defense wargames, MDIEs, GTs and SIFTs. For the purposes of this analysis, all integrated tests with the exception of the SIFTs involve only ground-based components. The SIFTs could include a combination of any of the existing or planned land-, sea-, or air-based weapons components, and any land-, sea-, air- or space-based sensors and support assets. Integrated testing would determine the ability of the evolving C2BMC to integrate the BMDS components. The SIFTs will be discussed in terms of existing and reasonably foreseeable test scenarios. Existing SIFTs leverage currently scheduled element tests. Future SIFTs would be developed with increasing fidelity and complexity. SIFTs would involve the launch of at least one target missile to be negated by either an interceptor missile or a laser. Several sensor systems would acquire and track the target missile and interceptor missile (or ABL), as well as the actual intercept. For each planned test intercept, debris impact zones would be established. SIFTs could cross multiple environment types. Testing would occur within the confines of the U.S. and surrounding BOAs, as well as at some select locations abroad. As the proposed BMDS grows in capability, testing would expand to include more international sites.

2.4.1.3 Alternative 1 - Deployment

Under Alternative 1, the BMDS missile interceptors and directed energy missile defense system components, and related architecture and assets would be deployed on land-, sea- and air-based platforms. See Section 2.3.3 for a discussion of Deployment as part of the acquisition life cycle. Because the BMDS is envisioned to be an evolving system with interchangeable interoperable components, there is no final architecture defined for the system. Deployment would require fielding and sustainment of BMDS components in the U.S. and at strategic locations abroad. Components would be deployed as they are deemed capable of functioning within the BMDS. Fielding activities such as manufacturing, site preparation and construction and transport of components to deployment sites would be required. Sustainment activities include operation and maintenance of components, training, upgrades, and service life extensions where appropriate.

2.4.1.4 Alternative 1 - Planning for Decommissioning

Decommissioning would involve the planning for the final demilitarization and disposal of the BMDS components and support assets no longer needed for the BMDS or its testing program (see Section 2.3.4). Plans for decommissioning BMDS components and facilities would be incorporated into site development activities. Under Alternative 1, decommissioning of weapons would involve the removal and disposal of rocket propellant and dismantlement and disposal of residual materials such as the missile shell. Both testing as well as deployed components and facilities may be decommissioned. Thus, target missiles would undergo similar decommissioning processes.

Decommissioning of sensors would include the recycling/reuse and disposal of residual materials associated with the antennae, electronic, cooling and power units. Space-based sensors would be abandoned in orbit, parked in a higher orbit, deorbited, retrieved, or reprogrammed for alternate uses. C2BMC hardware and software would be upgraded or removed and disposed according to applicable requirements. Fixed facility support assets would be assigned new missions, returned to their owners, or transferred to new owners. Mobile support assets such as transportation vehicles, missile launchers and launch vehicles would be refurbished and transferred to an alternate use, or dismantled and disposed.

2.4.2 Alternative 2 – Implement Proposed BMDS with Land-, Sea-, Air- and Space-based Weapons Platforms

In Alternative 2, the MDA would develop, test, deploy and plan to decommission land-, sea-, air- and space-based platforms for weapons and related architecture and assets. Alternative 2 would be identical to Alternative 1, with the addition of space-based defensive weapons. A space-based test bed would be considered and evaluated to determine the feasibility of using kinetic energy to intercept threat missiles from space.

This section describes the space-based weapons components and associated acquisition life cycle activities under Alternative 2. Individual components would be tested to determine the adequacy for military utility and ability to function in an integrated BMDS. In addition, the BMDS C2BMC architecture would be designed and tested to meet the needs of an integrated system.

2.4.2.1 Alternative 2 - Development and Testing

MDA is developing an exoatmospheric kill vehicle (EKV), which, as described in Section 2.2.1, acts as the kinetic energy weapon on an interceptor. EKVs could be launched as hit-to-kill weapons from a space-based platform. Under Alternative 2, the KEI is a potential space-based defensive weapon to counter threat ballistic missiles during boost phase. The development of midcourse and terminal phase defensive

weapons may be included as well. The new interceptor would have effectiveness similar to earlier interceptors but would achieve it by decreasing the mass of the interceptor and increasing the speed at which the interceptor travels. This interceptor may use existing or new boosters; however, a new EKV would likely be designed for the interceptor. The EKV would be adaptable and could be launched from a space-based platform. Testing of a space-based weapons platform would involve ground-based testing including modeling and simulations of space-based technology, as well as multiple launches to emplace prototype technology in orbit. The prototype would then be tested in increasing realistic scenarios involving simulated and actual intercepts of targets. The Near-field Infrared Experiment (NFIRE) spacecraft could be launched on a Minotaur space launch vehicle from Wallops Flight Facility. The spacecraft bus would be shipped unfueled; however, the payload would be shipped fully fueled from the manufacturer. Spacecraft integration with the booster would also occur at Wallops Flight Facility.

2.4.2.2 Alternative 2 - Deployment

MDA would deploy EKVs and space-based launch platforms to deploy a space-based weapons component, currently envisioned as the KEI. The MDA would also obtain launch services to deploy the launch platform satellite and weapons components into their orbits. They could use Evolved Expendable Launch Vehicles launched from Vandenberg AFB and Cape Canaveral.

2.4.2.3 Alternative 2 - Planning for Decommissioning

A space-based weapons platform resembling a satellite would be decommissioned by being abandoned in orbit, parked in a higher orbit, deorbited, or retrieved. A weapons platform carrying a sensor system could have alternate uses including monitoring rocket launches and aircraft flights. MDA or the military services would make decisions on the disposition of the space-based weapons platforms based on the stability of the orbits, the costs and risks of deorbiting or retrieval, the remaining useful life of the equipment, and potential for alternate uses.

2.5 No Action Alternative

Under the No Action Alternative, the MDA would not test, develop, deploy, or plan for decommissioning activities for an integrated BMDS. Instead, the MDA would continue existing test and development of discrete missile defense systems as stand-alone defensive capabilities.

Under the No Action Alternative, individual components would continue to be tested to determine the adequacy of their stand-alone capabilities, but would not be subjected to integrated system-wide tests. In addition, the C2BMC architecture would be designed

around the needs of individual components and would not be designed or tested to meet the needs of an integrated system.

The approach and methods for deployment and decommissioning of components under the No Action Alternative would be the same as under the proposed action. However, deployment of individual components could occur earlier under the No Action Alternative because they would not undergo System Integration Testing. In addition, a greater number of units of the components may need to be deployed to provide a comparable number of opportunities to intercept threat missiles as provided by an integrated system.

Failure to deploy a fully integrated BMDS could result in the inability to respond to a ballistic missile attack on the U.S. or its deployed forces, allies and friends in a timely and successful fashion. This could result in the successful attack on one or more large population centers with chemical, biological, or nuclear weapons of mass destruction. The threat of such an attack could also jeopardize national security interests. Further, this alternative would not meet the purpose of or need for the proposed action or the specific direction of the President and the U.S. Congress.

2.6 Alternatives Considered But Not Carried Forward

2.6.1 Cancel Development of Ballistic Missile Defense Capabilities

As suggested to the MDA during the scoping process, one alternative would involve canceling the development of all ballistic missile defense capability development and testing. Such an alternative would rely upon diplomacy and military measures to deter missile threats against the U.S. However, this proposed alternative would eliminate the capability to defend the U.S., its deployed forces, allies, or assets from a ballistic missile attack should diplomacy or other deterrents fail. This alternative does not meet the purpose of or need for the proposed action as described in Sections 1.3 and 1.4, respectively; does not meet the direction of the President and the U.S. Congress; and therefore will not be analyzed further.

2.6.2 Single or Two-Platform BMDS

MDA has evaluated the threat environment (potential launch locations, missile flight paths, and target locations) and concluded that an effective missile defense should include components based on at least the land, sea, and air. Alternatives that provide only one or two platforms would reduce the capability of the BMDS to defend the U.S., its deployed forces, allies, or assets from a ballistic missile attack. This could result in the successful attack on one or more large population centers with chemical, biological, or nuclear weapons of mass destruction. The threat of such an attack could also jeopardize national security interests. Therefore, alternatives that provide a BMDS with only one or two platforms will not be carried forward for further analysis.

This page intentionally left blank.

3 AFFECTED ENVIRONMENT

Introduction

This Section discusses the biomes, ocean areas, and the atmosphere that comprise the Affected Environment in this PEIS, as well as the resource areas that could be impacted by the proposed action. This Section defines each resource area (Section 3.1) and discusses those resource areas within the context of a particular biome, ocean area or the atmosphere (Section 3.2).

The Affected Environment includes all land, air, water, and space environments where proposed activities are reasonably foreseeable. The Affected Environment considered in this PEIS includes specific locations in the U.S. and areas outside the U.S. As a result, applicable international treaties, foreign national laws and U.S. Federal, state, and local laws and regulations must be considered. The description of each resource area in Section 3.1 includes potentially relevant legal requirements and provides a roadmap of issues to consider for impacts assessment of a tiered document along with a determination of significance of the impacts. Appendix G contains additional information about laws and regulations that should be considered for subsequent impact analyses.

The Affected Environment for this PEIS examines global biomes[32] where development, testing, deployment, and planning for decommissioning activities for the proposed integrated BMDS may occur.

The biomes each cover a broad region, both geographically and ecologically. The distribution of global biomes is widely documented and accepted within the scientific community, and classification of biomes is based upon the characteristics of climate, geography, geology, vegetation, and wildlife.[33] Using biomes as affected environment designations captures the relevant differences between environments in a way that supports a useful analysis of impacts and allows future site-specific environmental documentation to tier from this PEIS. Note that there are no reasonably foreseeable BMDS activities occurring in Antarctica. For this reason, this continent does not appear on any of the biome maps in the PEIS.

---

[32] Merriam-Webster defines biome as a major ecological community type (as tropical rain forest, grassland, or desert). (Merriam-Webster Online Dictionary, 2004)

[33] *Biogeography*, 2nd ed. James H. Brown and Mark V. Lomolino. Pages 110-111. Sinauer Associates, Inc. Publishers, 1998. (stating “[E]cologists and biogeographers have almost without exception classified terrestrial [ecosystems] on the basis of the structure or [natural features] of the vegetation.”)

The Affected Environment in this PEIS is divided into nine terrestrial biomes, the BOA, and the Atmosphere as identified below.

- Arctic Tundra
- Sub-Arctic Taiga
- Deciduous Forest
- Chaparral
- Grasslands
- Desert
- Tropical
- Savanna
- Mountain
- BOA
- Atmosphere

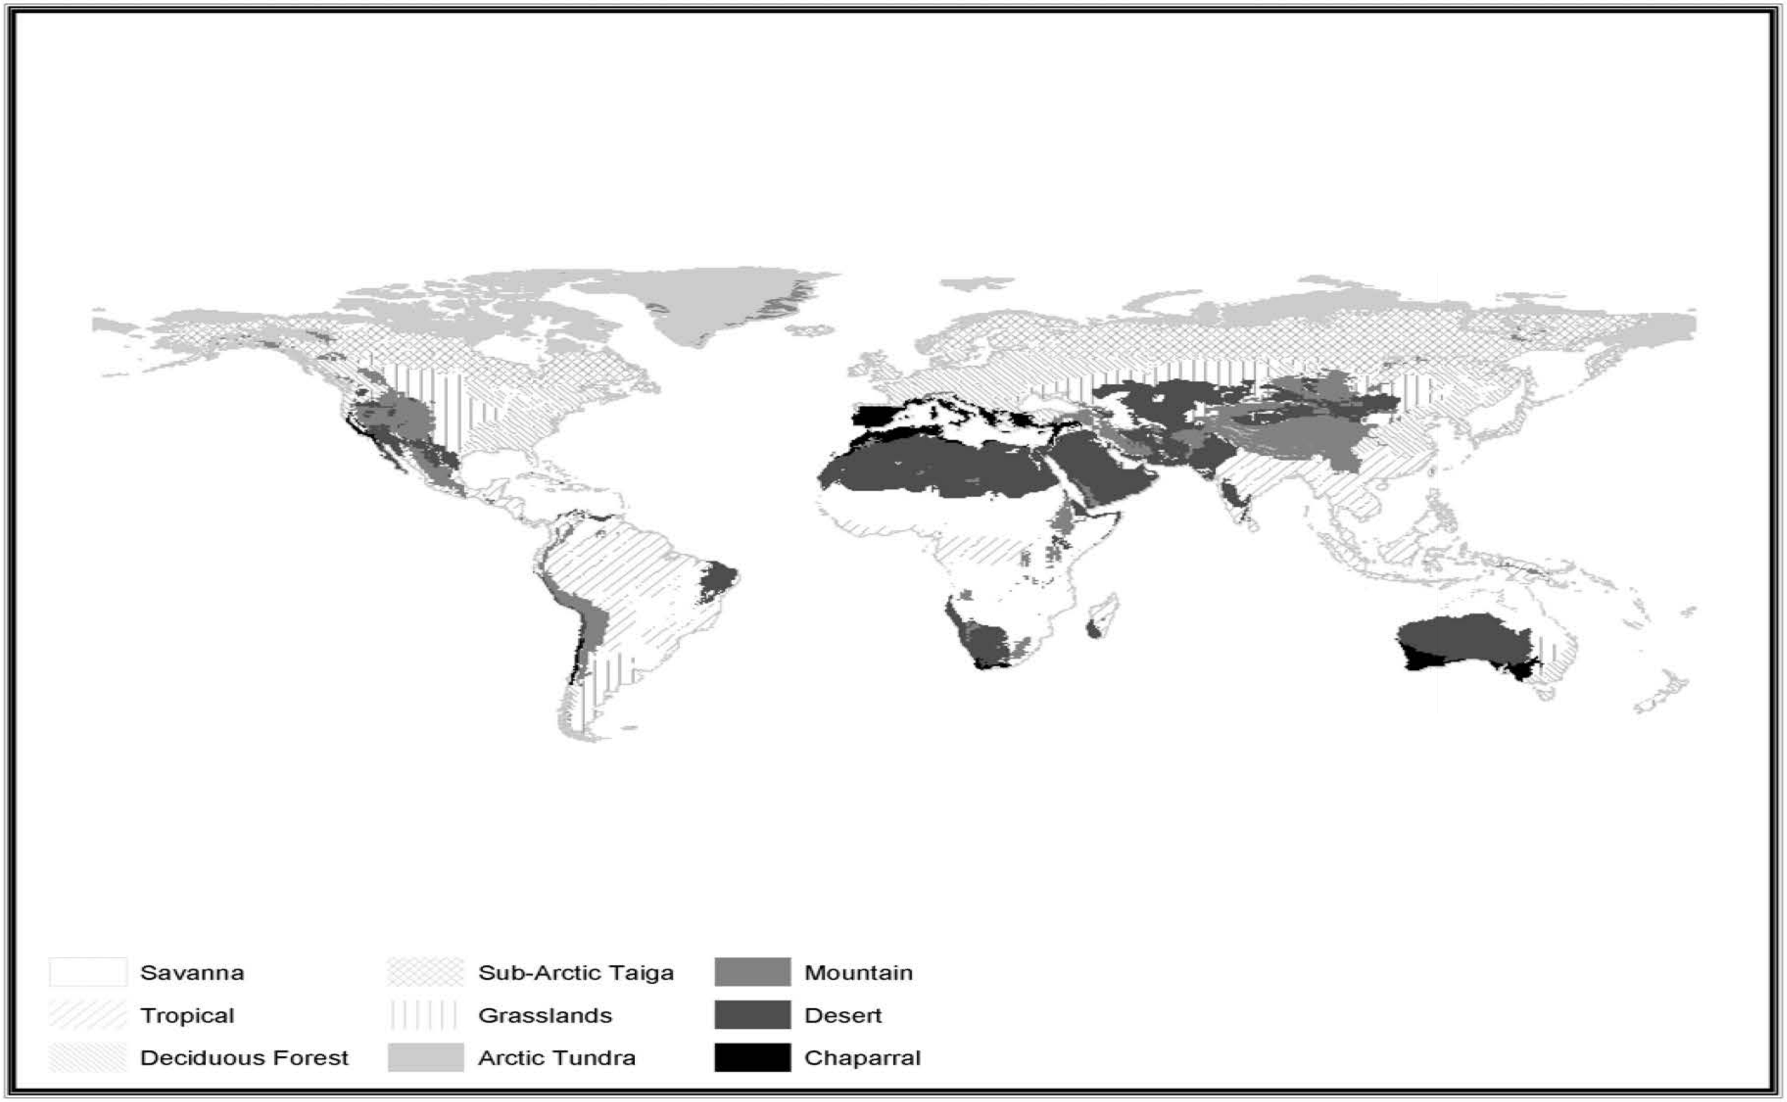
Exhibit 3-1 shows the global distribution of the various terrestrial biomes (not including the BOA and the Atmosphere). Biomes may be further subdivided based on geographic location; however, this PEIS considers nine overarching terrestrial biomes.

The characteristics (e.g., climate, geology, flora and fauna) that define a global biome are the same regardless of whether the biome area of concern is coastal or inland. However, unique features (e.g., wetlands, estuaries, wind currents, hurricanes) of coastal areas[34] may affect determination of environmental impacts. Therefore, the Affected Environment discusses these unique features within the biome descriptions. Describing coastal areas as part of the larger inland biomes minimizes repetition among the descriptions yet captures the important aspects of the coastal areas in a way suitable for impacts analysis.

Each biome description contains representative examples of past, current, or proposed locations used by the MDA within that biome. Therefore, an entity tiering from the PEIS would be able to map a particular site to its applicable biome. For example, WSMR in New Mexico is located within the Desert Biome. The description of the Desert Biome describes the particular characteristics of the biome that could affect the impacts of activities proposed at WSMR, or other locations in this biome.

[34] For the purposes of this PEIS, the coastal area includes the near shore, which is an indefinite zone extending seaward from the shoreline beyond the breaker zone, and is not coextensive with the area afforded protection under the Coastal Zone Management Act. This typically includes water depths of less than 20 meters (65 feet). The inland portion of the coastal area includes shoreline, tidal wetlands, coastal wetlands, and coastal estuaries.

Exhibit 3-1. Map of Global Biomes



Source: Modified From National Geographic, 2003b

- **Arctic Tundra Biome.** The Arctic Tundra Biome as described in Section 3.2.1 is located in areas above 60^{o} North latitude.[35] The areas of potential interest for the BMDS in the Arctic Tundra Biome include the arctic regions of North America and the arctic coastal regions that border the North Atlantic Ocean, North Pacific Ocean, and Arctic Ocean, including portions of Alaska, Canada, and Greenland (administered by Denmark).

- **Sub-Arctic Taiga Biome.** The Sub-Arctic Taiga Biome as described in Section 3.2.2 occurs between 50° to 60° North latitudes. The areas of interest in the Sub-Arctic Taiga Biome include the sub-arctic regions of North America and the sub-arctic coastal regions that border the North Pacific Ocean, including portions of Alaska.

- **Deciduous Forest Biome.** The Deciduous Forest Biome as described in Section 3.2.3 is located in the mid-latitude, which means that it is found between the Polar Regions and the tropics. The areas of interest in the Deciduous Forest Biome include the eastern and northwestern U.S. and portions of Europe.

- **Chaparral Biome.** The Chaparral Biome as described in Section 3.2.4 occurs on the west coastal regions of continents between 30° and 40° North and South of the equator. The Chaparral Biome areas of interest include a portion of the California Coast and the coastal region of the Mediterranean from the Alps to the Sahara Desert and from the Atlantic Ocean to the Caspian Sea.

- **Grasslands Biome.** The location of the Grasslands Biome as described in Section 3.2.5 is not limited to a particular latitude range. Instead, Grasslands occur in the middle of all continents, except Antarctica. The areas of interest in the Grasslands Biome include prairie regions of the Midwestern U.S.

- **Desert Biome.** The Desert Biome as described in Section 3.2.6 is located between 15° and 35° North and South of the equator. The area of interest in the Desert Biome includes the western arid environment of the southwestern U.S.

- **Mountain Biome.** The Mountain Biome as described in Section 3.2.7 occurs in areas with high elevations just below and above the snow line of a mountain. The area of interest in the Mountain Biome includes the Rocky Mountains in the western U.S. and the Alps in central Europe.

---

[35] The latitudinal designations identify the general location for each biome; however, the biomes do not have rigid edges that begin and end at these latitudes. Therefore, there may be some overlap of biomes at or near these latitudinal designations.

- **Tropical Biome.** The Tropical Biome as described in Section 3.2.8 occurs between the Tropic of Cancer (23.5° North) and the Tropic of Capricorn (23.5° South). The area of interest in the Tropical Biome includes the Hawaiian Islands.

- **Savanna Biome.** The Savanna Biome as described in Section 3.2.9 occupies latitudes between 5º and 20º North and South of the equator. The area of interest in the Savanna Biome includes northern Australia.

- **Broad Ocean Area (BOA) Environment.** For the purposes of this PEIS, the BOA Environment as described in Section 3.2.10 includes the Pacific Ocean, the Atlantic Ocean, and the Indian Ocean.

- **Atmosphere Environment.** The Atmosphere Environment as described in Section 3.2.11 includes the atmosphere that envelops all areas of the Earth and consists of four principal layers: troposphere, stratosphere, mesosphere, and ionosphere (or thermosphere).

The description of the Affected Environment must be specific enough to allow meaningful assessment of potential impacts, yet broad enough to encompass all potential locations. The information in this Section and analysis in Section 4 do not purport to address site-specific issues. Additional analyses may be required to determine site-specific impacts for a proposed action.

The Affected Environment is discussed in terms of the following resource areas: air quality; airspace; biological resources; cultural resources; environmental justice; geology and soils; hazardous materials and hazardous waste; health and safety; land use; noise; socioeconomics; transportation; utilities; visual resources; and water resources. These areas represent the resources that the proposed BMDS may impact and were identified based on review of previous environmental documentation for the MDA, the DoD, and other agencies that conduct activities similar to those proposed for the BMDS (e.g., U.S. Air Force, NASA, FAA).

Definitions and descriptions are provided below for each resource area followed by a discussion of the issues that an impact assessment should address. Some resource areas are not analyzed in Section 4 of this PEIS, because they depend upon local factors and conditions and are too dependent on local information requirements to discuss meaningfully at a programmatic level. These resource areas include: cultural resources, environmental justice, land use, socioeconomics, utilities, and aesthetics (visual resources).

3.1 Resource Areas

3.1.1 Air Quality

Definition and Description

Air quality is determined by the type and amount of pollutants emitted into the atmosphere, the size and topography of the air basin, the prevailing meteorological conditions, and the location of sensitive receptors relative to the source of the emission of air pollutants. Air pollutants of concern fall into four categories.

- **Criteria Air Pollutants**. These are a group of seven pollutants identified in the Clean Air Act for which the U.S. EPA is required to establish allowable concentrations in ambient air: sulfur dioxide (SO_2), carbon monoxide (CO), nitrogen dioxide (NO_2), ozone (including the compounds that contribute to its formation - volatile organic compounds [VOCs] and nitrogen oxides [NO_X]), particulate matter (PM) with a diameter of less than ten microns (PM_{10}), particulate matter of with a diameter of 2.5 microns or less ($PM_{2.5}$), and lead.

- **Hazardous Air Pollutants (HAPs)**. These are a group of 188 chemicals identified in the 1990 Clean Air Act Amendments (40 U.S.C. 7412(b)). Exposure to these pollutants has been determined to cause or contribute to cancer, birth defects, genetic damage, and other adverse health effects. Examples of HAPs include benzene, asbestos, and carbon tetrachloride.

- **Mobile Source Air Toxics**. These are a group of 20 HAPs plus “diesel PM and diesel exhaust organic gases,” which are complex mixtures that contain numerous HAPs.

- **Regional Haze Pollutants**. The principle air pollutants that cause regional haze are SO_2, NO_X, VOC, PM_{10}, $PM_{2.5}$, and ammonia. The fraction of PM in the $PM_{2.5}$ size range is the most active component of PM in visibility degradation. SO_2, NO_X, VOC, and ammonia all undergo chemical transformations that result in the formation of sulfate, nitrate, and organic aerosols in the fine size range.

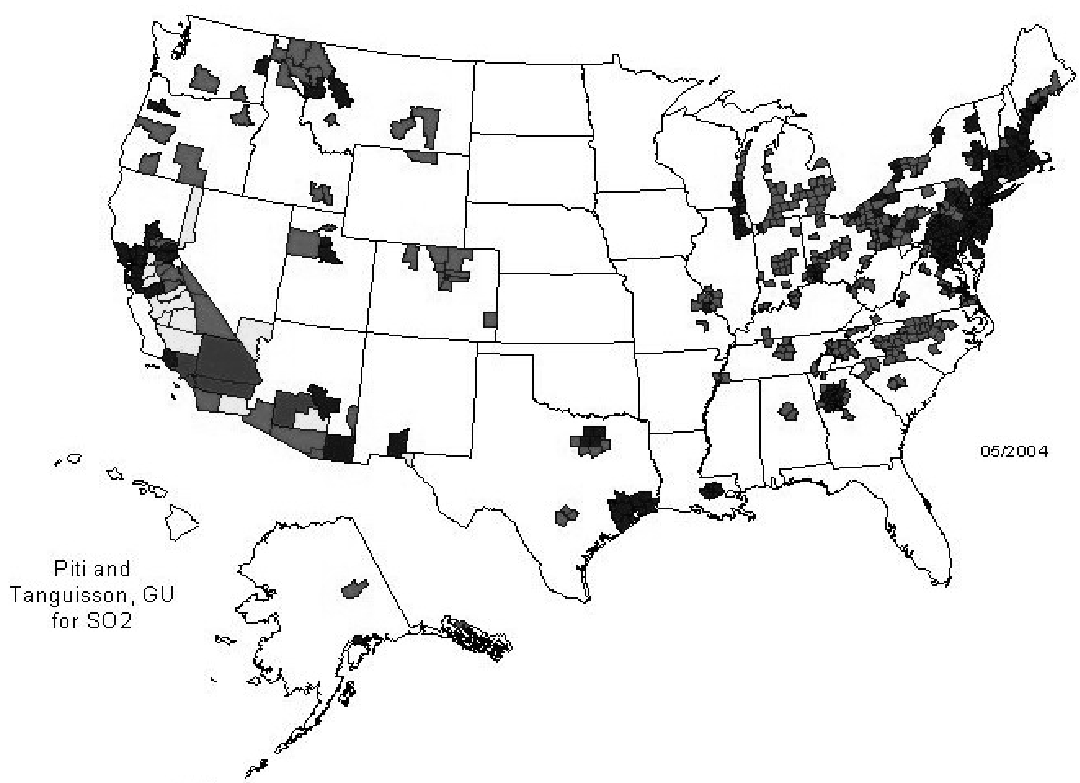
Sources of air pollutants include stationary sources (e.g., industrial facilities, refineries, power plants, launch pads), area sources (which are a collective representation of sources not specifically identified), mobile sources (e.g., motor vehicles, ships, aircraft, off-road engines, mobile platforms), and biogenic (natural) sources (e.g., forest fires, volcanoes).

The size and topography of the air basin, as well as the prevailing meteorological conditions determine how air pollutants are dispersed. Air currents carry secondary

pollution from one region to another, often increasing the background levels of air pollutants for the recipient regions. Such conditions are addressed in the Clean Air Act Section 184, which defines an Ozone Transport Region that includes Connecticut, Delaware, Maine, Maryland, Massachusetts, New Hampshire, New Jersey, New York, Pennsylvania, Rhode Island, Vermont, and Washington D.C. The emission standards are more protective in Ozone Transport Regions. An example of secondary pollution would be ozone (smog) created when NO_X and VOCs react in the presence of sunlight. The NO_X and VOCs could be released into the atmosphere a long distance from where the ozone ultimately degrades the air quality.

The Clean Air Act (42 U.S.C. 7401) requires the adoption of National Ambient Air Quality Standards (NAAQS) to protect the public health, safety, and welfare from known or anticipated effects of criteria air pollutants. According to EPA guidelines, an area with air quality better than the NAAQS is designated as being in attainment, while areas with worse air quality are classified as non-attainment areas. Pollutants in an area may be designated as unclassified when there are insufficient data for the EPA to identify attainment status. Current non-attainment areas in the U.S. are indicated in Exhibit 3-2.

Exhibit 3-2. Non-Attainment Areas for Criteria Pollutants January 2004



Note: Map is shaded by county to indicate the number of criteria pollutants for which the county is in non-attainment. However, the purpose of this exhibit is to generally illustrate the location of non-attainment areas in the U.S.

Source: EPA, 2004

The official list of non-attainment areas and a description of their boundaries can be found in the CFR at 40 CFR Part 81 and pertinent FR notices. EPA maintains an unofficial list on the Internet at http://www.epa.gov/oar/oaqps/greenbk/. As of February 2004, there were 68 non-attainment and 69 maintenance areas for ozone, 59 nonattainment and 24 maintenance areas for PM_{10}, 11 nonattainment and 65 maintenance areas for CO, 22 nonattainment and 30 maintenance areas for SO_2, and eight maintenance areas for lead.

For areas that are designated non-attainment, the Clean Air Act establishes levels and timetables for each region to achieve attainment of the NAAQS. States must prepare a State Implementation Plan (SIP), which documents how the region will reach its attainment levels by the required date. The SIP includes inventories of emissions within the area and establishes emissions budgets that are designed to bring the area into compliance with the NAAQS. In maintenance areas, the SIP documents how the state intends to maintain compliance with NAAQS.

Section 176(c) of the Clean Air Act prohibits Federal entities from taking actions in non-attainment or maintenance areas that do not "conform" to the SIP. The purpose of the conformity regulation is to ensure that Federal activities 1) do not interfere with the budgets in the SIPs; 2) do not cause or contribute to new violations of the NAAQS; and 3) do not impede the ability to attain or maintain the NAAQS. In November 1993, EPA promulgated two sets of regulations to implement CAA section 176(c):

- The Transportation Conformity Regulations, which establish the criteria and procedures for determining that transportation plans, programs, and projects funded under Title 23 U.S.C. or the Federal Transit Act conform to the SIP. The transportation conformity regulations are codified in 40 CFR 93, in Subpart A.

- The General Conformity Regulations, which ensure that other Federal actions also conform to the SIPs, and are applicable to all other Federal actions not covered under Transportation Conformity. The General Conformity regulations are codified in 40 CFR 93, Subpart B. All Federal actions are covered unless otherwise exempt (such as actions covered by transportation conformity, exempt actions listed in the rule, and cases where the action does not create emissions above the *de minimis* threshold levels specified by EPA regulations in 40 CFR 93.153(b)).

The proposed action is subject to the General Conformity Regulations, not Transportation Conformity Regulations. Under the General Conformity Regulations, MDA is required to determine whether the proposed action and alternatives would result in emissions within a non-attainment or maintenance area that would exceed established *de minimis* levels or would be regionally significant (i.e., exceed ten percent of the emission inventory). If so, MDA must make a General Conformity Determination in accordance

with EPA requirements. Exhibit 3-3 shows *de minimis* levels of pollutants for various non-attainment levels.

Exhibit 3-3. General Conformity *De Minimis* Levels

Criteria Pollutant	Area Designation	Pollutant	*De Minimis* Level, metric tons per year (tons per year)
Ozone	Extreme Non-attainment	NO_X or VOC	9 (10)
	Severe Non-attainment	NO_X or VOC	23 (25)
	Serious Non-attainment	NO_X or VOC	45 (50)
	Other Non-attainment with Transport	NO_X	91 (100)
	Other Non-attainment with Transport	VOC	45 (50)
	Other Non-attainment without Transport	NO_X or VOC	91 (100)
	Maintenance	NO_X	91 (100)
	Maintenance with Transport	VOC	45 (50)
	Maintenance without Transport	VOC	91 (100)
PM_{10}	Serious Non-attainment	PM_{10}	64 (70)

Source: 40 CFR 93.153(b)

The Clean Air Act lists 188 HAPs, which are individual chemicals or elements that have been linked to observed human health effects such as increased risk of cancer, damage to the immune system, neurological problems, damage to reproductive systems (e.g., reduced fertility) and developmental systems, respiratory damage, and other health problems. Details on precisely how each HAP affects humans can be found in EPA's Integrated Risk Information System, a database available to the public.[36] The elemental

[36] EPA, 2003c

HAPs are primarily metals and families of metallic compounds (e.g., mercury compounds, arsenic compounds). The remaining HAPs are primarily organic compounds and selected inorganic gaseous compounds. Benzene, ethyl chloride, and pentachlorophenol are examples of organic HAPs. Hydrochloric acid and hydrogen fluoride are examples of inorganic HAPs.

The Clean Air Act regulations include a regional haze rule (64 FR 35714 [July 1, 1999]) that requires states to develop SIPs to address visibility at designated mandatory Class I areas, including 156 designated national parks, wilderness areas, and wildlife refuges. General features of the regional haze rule are that all states are required to prepare an emissions inventory of all haze related pollutants from all sources in all constituent counties. Most states will develop their regional haze SIPs in conjunction with their $PM_{2.5}$ SIPs over the next several years.

Another concern with respect to air quality is greenhouse gas emissions. The primary greenhouse gas emitted by anthropogenic or human-derived activities in the U.S. is CO_2, which represented approximately 84 percent of total greenhouse gas emissions in 2001. The largest source of CO_2, and of overall greenhouse gas emissions, is fossil fuel combustion, both from stationary (power plants, industry and manufacturing processes) and mobile sources (automobiles, trucks, construction equipment, lawn mowers). Electric power generation, from utilities and non-utilities combined, accounted for the largest source of U.S. greenhouse gas emissions in 2001, closely followed by transportation sources and industrial processes. On an annual basis, the overall consumption of fossil fuels in the U.S., and therefore emissions from the combustion of those fuels, generally fluctuates in response to changes in general economic conditions, energy prices, weather (temperature extremes during winters and summers), and the availability/acceptance of non-fossil fuel alternatives.

Although CO, NO_X, VOCs, and SO_2 do not have a direct global warming effect, they are regulated because of their role in influencing the formation and destruction of tropospheric (ground-level) and stratospheric (upper atmosphere) ozone. CO is produced when carbon-containing fuels are combusted incompletely. NO_X (i.e., nitrogen oxide [NO] and NO_2) originate predominantly from fossil fuel combustion, with the majority of emissions from mobile sources, but also from stationary sources. VOCs, which include hundreds of organic compounds that participate in atmospheric chemical reactions, are emitted primarily from transportation, industrial processes, and non-industrial consumption of organic solvents. In the U.S., SO_2 is primarily emitted from coal combustion for electric power generation and from the metals industry. (EPA, 2003b)

Impact Assessment

MDA activities that would contribute to air quality impacts include actions that emit criteria pollutants, HAPs, mobile source air toxics, or regional haze pollutants, as well as

compounds that would affect climate change. MDA actions that would result in the emission of such pollutants and compounds include missile launches, operation of internal combustion and jet engines, incineration, heating and cooling of facilities and components, use of fuel storage tanks, fueling activities, and construction. Best available control technologies are applied to new emissions sources and to sources that are modified to minimize the effects that MDA activities would have on air quality. Impacts on the regulated local and regional air quality from activities related to the proposed BMDS would result from construction and operation activities at specific locations, launch related activities, and other general activities. The emission of CO_2 and ozone-depleting substances associated with the proposed BMDS has the potential to result in climate change impacts.

Construction and Operations Activities

Emissions resulting from site preparation and construction activities as well as new or increased operations activities would include PM, CO, NO_X, sulfur oxides (SO_X), and VOC. The use of construction and supply equipment may increase all types of emissions. Emissions due to new or increased site operations activities would result from

- Increase in overland shipments related to new or increased operations;
- Use of new equipment and generators or increased use of existing equipment and generators;
- Relocation of support personnel and localized increase in commuter traffic;
- Use of new fuel storage facilities or the increased use of existing fuel storage facilities;
- Use of new facilities and associated infrastructure (boilers, solvent degreasing, painting, used oil, spills, and incineration) or the increased use of existing facilities and associated infrastructure; and
- Use of earth-moving equipment during construction.

Emissions should be determined using EPA emissions factors and compared against ambient air quality standards. The emissions associated with industrial operations would be compared against historically similar operations or by methods outlined in the toxics release inventory, as necessary.

Launch Emissions

Emissions resulting from launch related activities would include CO, NO_X, PM, SO_X, VOC, and hydrogen chloride (HCl). The analysis of launch emissions impacts can be considered in two categories, above and below 914 meters (3,000 feet). The 914-meter (3,000-foot) altitude is an appropriate threshold because the EPA uses this altitude for determining contributions of emissions to ambient local and regional air quality. EPA emissions factors should be used to determine emissions fractions for each emission

source for emissions above and below 914 meters (3,000 feet). Total emissions should be estimated by multiplying emissions fractions by the total amount of propellant used.

Determination of Significance

For actions that would occur in the U.S. within a non-attainment or maintenance area, the total annual emission of each criteria pollutant would be calculated and would be compared against EPA *de minimis* levels. Annual emissions values that exceed the *de minimis* level or ten percent of the total emission budget of the non-attainment or maintenance area, or state or local ambient air quality standards would be considered significant and would require a general conformity evaluation.

The risk associated with the emissions of HAPs on sensitive receptors within the U.S. would be evaluated. (EPA, 1999) Risk factors that exceed acceptable levels established by EPA would be considered significant. Emissions within the U.S. would also be compared against the requirements and standards included in SIPs to address visibility at Class 1 areas (156 designated national parks, wilderness areas, and wildlife refuges). Emissions that exceed the regional haze standard of an SIP would be considered a significant impact. Actions proposed to occur outside of the U.S. and its territories would be reviewed in accordance with applicable international or foreign ambient air quality standards. Emissions that would occur in locations that violate applicable international or foreign laws would be considered significant.

The effects of emissions that would occur above an altitude of 914 meters (3,000 feet) would be reviewed for potential contribution to ozone depletion (particularly in the upper troposphere/stratosphere), acid rain, and global warming. To determine the significance of impacts to air quality, emission levels would be compared with studies of other similar emissions, as well as U.S. or global emissions of ozone-depleting substances, acids and greenhouse gases (e.g., CO_2). Annual emissions greater than one percent of the global emissions, annual MDA program emissions that exceed the average level of emissions associated with the program over the preceding three years by more than ten percent or single events that exceed one percent of the global emissions would be considered significant.

3.1.2 Airspace

Definition and Description

Airspace refers to the space that lies above a nation and comes under its jurisdiction. Airspace is a finite resource that can be defined vertically and horizontally, as well as temporally. Time is an important factor in airspace management and air traffic control. The FAA has established various airspace designations to protect aircraft while operating near and between airports and while operating in airspace identified for defense-related

purposes. Flight rules and air traffic control procedures govern safe operations in each type of designated airspace. Military operations follow specific procedures to maximize flight safety for both military and civil aircraft.

The types of airspace are defined by the complexity or density of aircraft movements, the nature of operations conducted within the airspace, the level of safety required, and the national and public interest in the airspace. The classes of airspace are controlled, uncontrolled, special use, and other airspace, as defined in Exhibit 3-4.

Exhibit 3-4. Definitions of Airspace Categories

Category	Definition	Examples
Controlled Airspace	Airspace used by aircraft operating under Instrument Flight Rules (IFR) that require different levels of air traffic service	Altitudes above Flight Level (FL) 180 (5,500 meters [18,000 feet] above MSL) Airport Traffic Areas Airport Terminal Control Areas Jet Routes Victor Routes
Uncontrolled Airspace	Airspace primarily used by general aviation aircraft operating under Visual Flight Rules (VFR)	As high as 4,420 meters (14,500 feet) above MSL
Special Use Airspace	Airspace within which specific activities must be confined or access limitations are placed on non-participating aircraft	Restricted Areas Military Operating Areas (MOA)
Other Airspace	Airspace not included under controlled, uncontrolled, or special use categories	Military Training Routes

Controlled Airspace

Controlled Airspace covers airspace used by aircraft operating under IFR that require different levels of air traffic service. As shown in Exhibit 3-4, examples of controlled airspace include the altitudes above FL 180 (approximately 5,500 meters (18,000 feet) above MSL, some Airport Traffic Areas, and Airport Terminal Control Areas. General controlled airspace includes the established Federal airways system, which consists of the high altitude (Jet Routes) system flown above FL 180, and the low altitude structure (Victor Routes) flown below FL 180.

Controlled airspace has numerous designations from Class A to Class G depending upon the degree of airspace control required to maintain flight safety. Airspace in North America contains “North American Coastal Routes,” which are numerically coded routes

preplanned over existing airways and route systems to and from specific coastal fixes. North American Routes consist of

- **Common Route/Portion.** That segment of a North American Route between the inland navigation facility and the coastal fix.

- **Noncommon Route/Portion.** That segment of a North American Route between the inland navigation facility and a designated North American terminal.

- **Inland Navigation Facility.** A navigation aid on a North American Route at which the common route and/or the noncommon route begins or ends.

- **Coastal Fix.** A navigation aid or intersection where an aircraft transitions between the domestic route structure and the oceanic route structure.

During peak air travel times in the U.S., there are about 5,000 airplanes in the sky every hour. This translates to approximately 50,000 aircraft operating in U.S. skies each day. The U.S. airspace is divided into 21 zones (centers), and each zone is divided into sectors. Also within each zone are portions of airspace, about 81 kilometers (50 miles) in diameter, called Terminal Radar Approach Control airspaces. Multiple airports exist within each of these airspaces and each airport has its own airspace with an eight-kilometer (five-mile) radius.

Uncontrolled Airspace

Uncontrolled Airspace is primarily used by general aviation aircraft operating under VFR and generally refers to airspace not otherwise designated and operations below 365.8 meters (1,200 feet) above ground level. Uncontrolled airspace is not subject to the strict conditions of flight required by those aircraft using controlled airspace and can extend as high as 4,420 meters (14,500 feet) above MSL.

Special Use Airspace

Special Use Airspace is airspace within which specific activities must be confined or for other reasons, access limitations are imposed upon non-participating aircraft. The types of Special Use Airspace are

- **Alert Areas.** Alert areas are airspace in which a high volume of pilot training activities or unusual aerial activity takes place. The activities within alert areas are not considered hazardous to aircraft and are conducted in accordance with FAA regulations. Both participating and transiting aircraft are responsible for collision avoidance. (FAA, 2003)

- **Restricted Areas.** Restricted areas contain airspace identified by an area on the surface of the earth within which the flight of aircraft, while not wholly prohibited, is subject to restriction. Activities within these areas are confined to permitted activities and limitations are imposed upon all other aircraft operations. Restricted areas generally are used to contain hazardous military activities. The term “hazardous” implies, but is not limited to, weapons deployment (these areas also are referred to as controlled firing areas and may be either live or inert), aircraft testing, and other activities that would be inconsistent or dangerous with the presence of non-participating aircraft.

- **MOAs.** MOAs include airspace designated for non-hazardous military activities and are established outside of controlled airspace below FL180. Typical activities that occur in MOAs include military pilot training, aerobatics, and combat tactics training. When MOAs are in use, non-participating aircraft flying under IFR clearances are directed by air traffic control to avoid the MOA. However, even when a MOA is in use, entry into the area by VFR aircraft is not prohibited, and flight by non-participating aircraft can occur on a see-and-avoid basis.

- **Prohibited Areas.** Prohibited areas include airspace where no aircraft may be operated without the permission of the using agency. This airspace is established for security and other national welfare reasons. (FAA, 2003)

- **Warning Areas.** Warning areas include airspace that may contain hazards to non-participating aircraft in international airspace. Warning areas are established beyond the 22.2-kilometer (12-nautical-mile) limit. Although the activities conducted within warning areas may be as hazardous as those in restricted areas, warning areas cannot be legally designated as restricted areas because they are over international waters. (FAA, 1996) By Presidential Proclamation No. 5928, December 27, 1988 (issued in 1989), the U.S. territorial limit was extended from 5.6 to 22.2 kilometers (three to 12 nautical miles). Special Federal Aviation Regulation 53 establishes certain regulatory warning areas within the new (5.6- to 22.2-kilometer [three to 12-nautical-mile]) territorial airspace to allow continuation of military activities while further regulatory requirements are determined.

Other Airspace

Other Airspace includes Military Training Routes. They are low altitude, high-speed routes established by the FAA as airspace for special use by the military services. Routes may be established as IFR Routes or VFR Routes. Military Training Routes are depicted on aeronautical charts and detailed descriptions are provided in the DoD Flight Information Publication AP/1B.

En route airways and jet routes are air corridors used by commercial and private aircraft. These corridors are generated based on the prevailing jet stream and their positions vary. The airways are identified by a “V” and a number designation and apply to altitudes up to 5.5 kilometers (18,000 feet). Jet routes are identified by a “J” and a number designation and apply to altitudes over 5.5 kilometers (18,000 feet). Coordination procedures used at locations where activities for the proposed BMDS may occur would prevent any potential impacts to aircraft in these routes.

Impact Assessment

Assessment of potential impacts on airspace would include a review and analysis of

- Projected volume and frequency of flights into airspace areas;
- Operating altitudes of vehicles, missiles, and targets;
- Lateral orientation of aircraft, missiles, and targets;
- Identification of airspaces that would be entered;
- Anticipated effect of the use of sensors on airspace availability;
- Effects of intercept or booster failure debris on airspace areas;
- Identification and description of the Region of Influence;
- Necessary approvals or agreements with controlling and using agencies for special use airspaces; and
- Comparison of airspace used by aircraft operating under IFR versus VFR.

Using this information, a map of the Region of Influence would be developed for the affected areas, as well as charts detailing the airspace areas and potential conflicts or approval hurdles. Specific activities may require letters of agreement to operate in certain airspace. Impacts on airspace due to activities associated with the proposed BMDS would be identified at the programmatic level and mitigated to the extent possible. Site-specific impacts on airspace would be addressed in site-specific documentation.

Determination of Significance

Actions that conflict with existing airspace use or designations where approvals or agreements with regulatory agencies cannot be obtained would be considered significant.

3.1.3 Biological Resources

Definition and Description

Native or naturalized vegetation (flora), wildlife (fauna), and the habitats they occupy are collectively referred to as biological resources. As part of the NEPA analysis, the potential impacts to all species potentially impacted by the proposed activity are

considered and evaluated. Special emphasis is placed on those species that are designated as sensitive. Plant and wildlife species may be designated as sensitive because of overall rarity, endangerment, unique habitat requirements, and restricted distribution. Generally, a combination of these factors leads to a sensitivity designation. Sensitive plant and wildlife species include those listed or proposed to be listed as threatened or endangered by the USFWS and National Oceanic and Atmospheric Administration (NOAA) National Marine Fisheries Service (NOAA Fisheries Service) under the Endangered Species Act, as well as those species listed by state wildlife resource agencies.

Federally or state listed species are afforded regulatory protection that involves a permitting process, including specific mitigation measures for any allowable (incidental) impacts to the species. Species proposed to be listed are treated similarly to listed species, but recommendations of the USFWS are advisory rather than mandatory in the case of proposed species. A federally listed endangered species is defined as any species, including subspecies that is in "in danger of extinction throughout all or a significant portion of its range." A federally listed threatened species is defined as any species "likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range." Proposed threatened or endangered species are those species for which a proposed regulation has been published in the FR, but a final rule has not been issued. In addition, the USFWS may designate critical habitat for threatened or endangered species. Critical habitat is defined as specific areas, within the geographical areas occupied by the species at the time it is listed, which contain the physical or biological features essential to conservation of the species and may require special management considerations or protection. In 2003, Congress amended the Endangered Species Act to allow the Secretary of the Interior to exempt DoD sites from critical habitat designations if adequate natural resources management plans are in place at the sites.

Federal agencies that propose to conduct activities that may impact a listed species or a species proposed to be listed are required to consult with the USFWS under Section 7 of the Endangered Species Act. Additional consultation activities with USFWS and other agencies with natural resource management responsibilities may be required under other applicable laws and regulations. A listing of relevant laws, regulations, and EOs is provided in Appendix G.

Impact Assessment

The impact analysis should include existing information on plant and animal species and habitat types in the vicinity of proposed sites, with special emphasis on the presence of any species listed as threatened or endangered by Federal or state agencies. In the U.S., proposed activities must be coordinated with the appropriate state wildlife agency to determine if threatened and endangered species or critical habitat exists within the region

of influence. If the proponent of the proposed activity determines that threatened or endangered species or critical habitat may be affected by the proposed action, the proponent would initiate either informal consultation or formal consultation under Section 7 of the Endangered Species Act. The consultation process may require the proponent of the proposed activity to conduct a biological assessment, resulting in a biological opinion from the resource agency. This opinion would include mitigation actions required of the proponent to ensure that impacts to species and habitat would be minimized.

If the proponent of the proposed action determines that marine mammals may be affected by the proposed action, the proponent should consult with NOAA Fisheries Service, Department of Interior, U. S. Fish and Wildlife Service, as appropriate, to ensure compliance with the Marine Mammal Protection Act. The Marine Mammal Protection Act established a moratorium, with certain exceptions, on the taking of marine mammals in U.S. waters and by U.S. citizens on the high seas, and on the importing of marine mammals and marine mammal products into the U.S. If the proponent of the proposed action determines that coral reefs or endangered fish habitat may be affected by the proposed action, the proponent should work with NOAA Fisheries Service to ensure all requirements are met.

If the proponent of the proposed activity determines that migratory bird species may be adversely impacted, then the proponent should consult with the USFWS's Regional Migratory Bird Program, to ensure compliance with the Migratory Bird Treaty Act and the Bald and Golden Eagle Protection Act. Under the Migratory Bird Treaty Act, the taking of migratory birds is not authorized without a permit. The project proponent should also consult with the USFWS to determine whether conservation measures may be implemented to minimize or avoid the take of migratory birds. MDA has included a technical appendix, Appendix N, considering the potential effects of radar on migratory birds.

MDA activities that could contribute to biological impacts include air emissions and noise from missiles, EMR or radio frequencies from sensors or support assets, habitat destruction through clearing activities, and construction and operations, as well as debris impacts.

Activities Resulting in Air Emissions

Air emissions from transportation vehicles, dust from clearing or construction, or launch emissions such as the ground cloud from lift-off could impact biological resources. The potential for launch emissions to impact local wildlife, vegetation, and specialized habitat, such as wetlands, should be considered.

Activities Resulting in Noise

Noise produced from missile launches and other activities related to the BMDS could affect biological resources. The potential for this noise to affect areas used by wildlife for migration, foraging, and breeding, should be considered.

Activities Resulting in EMR or Radio Frequencies

Radars and other equipment could emit EMR or radio frequencies, with the potential to impact biological resources. The analysis of EMR and radio frequency emissions should include the following metrics for review of Institute of Electrical and Electronics Engineers (IEEE) and American National Standards Institute (ANSI) standards for exposure to EM fields

- Peak and average power (modulation properties),
- Polarization of the EM field,
- Power density values for the beams over the range and azimuth of the sensor,
- Typical motion of the beams, and
- Size of the main and side beams.

Construction and Operation Activities

The impacts analysis should address construction activities and operations that could result in impacts to habitat including loss and restriction of habitat; light pollution; and leaks, spills, and other releases of contaminants. Noise impacts from operation of generators and construction equipment have the potential to impact species in the area. Other noise including sonic booms from launch and flight of missiles also should be analyzed for potential impacts on biological resources.

Debris Related Activities

Debris from booster failures or missile intercepts could impact biological resources. Debris would fall in pre-established impact zones on land or in water. The expected casualty to humans from debris produced during launches would be less than or equal to 30×10^{-6}. Debris recovery efforts, if required, would only occur on land and could result in impacts to biological resources from transportation activities. Such disturbances could include noise, emissions, fire caused by debris or unspent fuel, chemical payloads (such as tributyl phosphate), and surface disturbance impacts.

Determination of Significance

Actions that negatively affect a species or its habitat (critical habitat or essential fish habitat) protected under Federal or state law or an international treaty (e.g., Endangered

Species Act, Marine Mammal Protection Act, Magnuson-Stevens Fishery Conservation and Management Act), as well as other resources provided protection under Federal or state regulations or orders (e.g., Sikes Act, Migratory Bird Treaty Act, EO 13112 Invasive Species), where appropriate consultation or considerations have not been completed, documented, and implemented would be considered significant. In addition, it may be appropriate to consider multiple species habitat conservation planning efforts occurring in areas proximate to proposed BMDS activities.

3.1.4 Cultural Resources

Definition and Description

Cultural resources include prehistoric and historic artifacts, archaeological sites (including underwater sites), historic buildings and structures, and traditional resources (such as Native American and Native Hawaiian religious sites). Paleontological resources are fossil remains of prehistoric plant and animal species and may include bones, shells, leaves, and pollen.

Cultural resources of particular concern include properties listed or eligible for inclusion in the National Register of Historic Places (National Register). Only those cultural resources determined to be potentially significant under 36 CFR 60.4 are subject to protection from adverse impacts resulting from an undertaking. To be considered significant, cultural resources must meet one or more of the criteria established by the National Park Service that would make that resource eligible for inclusion in the National Register. The term “eligible for inclusion in the National Register” includes all properties that meet the National Register listing criteria which are specified in Department of Interior regulations at 36 CFR 60.4. Therefore, sites not yet evaluated may be considered potentially eligible for the National Register and, as such, are afforded the same regulatory consideration as nominated properties. Whether prehistoric, historic, or traditional, significant cultural resources are referred to as historic properties.

Impact Assessment

Because they possess unique qualities and characteristics, cultural and historic resources should be identified and analyzed in site-specific environmental documentation. The analysis should include consideration of the contemporary use of historic properties owned by the Federal government and intergovernmental cooperation and partnerships for the preservation and use of historic properties as required by EO 13287, Preserving America. MDA activities that could impact cultural resources primarily include construction, operation, and debris impacts.

Construction and Operation Activities

The analysis should address construction and operation activities that could result in ground disturbances, vibrations, significant air emissions, or leaks, spills, and other accidental releases of contaminants. The proponent should identify the region of influence for the activities and contact the appropriate State Historic Preservation Officer to determine whether there are any known listed or eligible sites in the vicinity and to determine whether mitigation measures are required, such as: site-specific cultural and historic surveys, records searches of the sacred lands of the Native American Heritage Commission to determine the presence of Native American cultural resources in the region of influence, contacting Native American individuals and organizations for additional information, and using a qualified archaeologist to monitor site-specific ground-disturbing activities during construction. If appropriate, construction-related personnel would be informed of the sensitivity of cultural resources and the penalties that could be incurred if sites are damaged or destroyed. If during construction, cultural items are discovered, activities should cease in the immediate area and the corresponding State or Tribal Historic Preservation Officer would be notified. Subsequent actions should follow the guidance provided.

Debris Related Activities

Debris resulting from booster failures and missile intercepts could impact cultural resources. However, prior to establishing debris impact zones, archeological, cultural and historic surveys would be conducted to determine the presence of such resources. Debris recovery efforts, if required, would only occur on land, but should not impact cultural resources outside the impact zone. Efforts would be made to mitigate any impacts of transportation, noise, emissions and surface disturbance during recovery efforts.

Determination of Significance

Actions that would destroy or alter the character of a historic property on, or eligible for inclusion on the National Register, or actions that would adversely affect a Native American or traditional cultural property, where appropriate consultation in accordance with the National Historic Preservation Act has not been completed, would be considered significant. Such consultations and mitigation measures must be approved by the appropriate State Historic Preservation Officer, Tribal Historic Preservation Officer, or the ACHP.

3.1.5 Environmental Justice

Definition and Description

Environmental Justice (EO 12898) is the fair treatment and meaningful involvement of all people regardless of race, color, national origin, or income with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies. Fair treatment means that no group of people, including a racial, ethnic, or socioeconomic group, should bear a disproportionate share of the negative environmental consequences resulting from industrial, municipal, and commercial operations or the exclusion of Federal, state, local, and tribal programs and policies. Meaningful involvement means that potentially affected community residents have an appropriate opportunity to participate in decisions about a proposed activity that would affect their environment or health; the public's contribution can influence the regulatory agency's decision; the concerns of all participants involved would be considered in the decision-making process; and the decision-makers would seek out and facilitate the involvement of those potentially affected.

Environmental Justice concerns include consideration of the race, ethnicity, and the poverty status of populations near the site of a proposed action. The CEQ defined "minority" to consist of the following groups: Black/African American, Asian, Native Hawaiian or Other Pacific Islander, American Indian or Alaska Native, and Hispanic populations (regardless of race). The Interagency Federal Working Group on Environmental Justice guidance states that a "minority population" may be present in an area if the minority population percentage in the area of interest is "meaningfully greater" than the minority population in the general population. The CEQ defined "low-income populations" as those identified with the annual statistical poverty thresholds from the Bureau of the Census. The accepted rationale in determining what constitutes a low-income population is similar to minority populations, in that when the low-income population percentage within the area of interest is "meaningfully greater" than the low-income population in the general population, the community in question is considered to be low-income.

Impact Assessment

Although each community is unique, there are several determination procedures that are common to most environmental justice assessments. One must first identify whether the geographic area under consideration qualifies as low-income or minority-based. To identify minorities or low-income populations, the Environmental Index methodology in EPA Region 6, Office of Planning and Coordination, dated 1996 would be used. Based on that guidance, environmental justice populations can be defined as meeting either of the following criteria

- Over one-half of the residents are minorities; or
- Over one-half of the households are low income.

An analysis of the most recent census data for the area provides this information. The U.S. Census Bureau maintains census data for racial classifications and income levels. The five racial classifications for which data are maintained are white, black, Hispanic, American Indian/Eskimo/Aleut, and Asian/Pacific Islander. Low-income data relates to those households that fall below the mean poverty level. Using these data, the percentages of minority and low-income populations may be determined for a particular geographic area.

After determining whether a minority or low-income population exists in the area, a determination must be made as to whether the proposed action would have a disproportionately high or adverse effect on those populations. The analysis involves first determining whether there are significant and adverse impacts and second whether those impacts disproportionately affect the minority or low-income population in the area. Where environmental justice concerns are found, the EPA recommends increased public involvement, perhaps as early as project scoping. Public participation and access to information are emphasized in EO 12898 and the Presidential Memorandum. The Presidential Memorandum instructs agencies to provide opportunities for community input throughout the NEPA process, including identifying potential effects and mitigation measures in consultation with the community and improving access to meetings, documents, and notices.

Environmental justice analyses require information about local communities, and therefore will be analyzed in site-specific environmental documentation.

Determination of Significance

Adverse environmental impacts that disproportionately affect minority or low-income populations would be considered significant.

3.1.6 Geology and Soils

Definition and Description

Geology and soils are those earth resources that may be described in terms of landforms, geology, and soil conditions. The makeup of geology and soils, including freshwater and marine sediments, could influence erosion, depletion of mineral or energy resources, seismic risk or landslide, structural design, and soil and ground water contamination resulting from proposed construction and operational activities.

Geology is the study of the composition and configuration of the Earth's surface and subsurface features. The general shape and arrangement of a land surface, including its height and the position of its natural and man-made features, is referred to as topography. The topography of the land surface can influence erosion rates and the general direction of surface water and ground water flow. Ground water is stored and transmitted underground in aquifers that supply lakes and rivers and is often used for human purposes, such as drinking water and irrigation for crops.

Geologic conditions also influence the potential for naturally occurring or human-induced hazards, which could pose risk to life or property. Such hazards could include phenomena such as landslides, flooding, ground subsidence, volcanic activity, faulting, earthquakes, and tsunamis (tidal waves). The potential for geologic hazards is described relative to each biome type's geologic setting. Exhibit 3-5 shows the geographic distribution for earthquakes in the continental U.S. Exhibit 3-6 shows landslide areas in the continental U.S.

Soils and sediments are the unconsolidated materials overlying bedrock or other parent material. Soils and sediments typically are described in terms of their composition, slope, and physical characteristics. Differences among soil and sediment types in terms of their structure, elasticity, strength, shrink-swell potential, and erosion potential affect their

Exhibit 3-5. Geographic Distribution for Earthquakes in the Continental U.S.

Source: USGS, 2002d

abilities to support certain applications or uses. In appropriate cases, soil and sediment properties must be examined for their compatibility with particular construction activities or types of land use. In a limited number of cases, the presence, distribution, quantity, and quality of mineral resources might affect or be affected by a proposed action.

Impact Assessment

Site preparation activities such as grading, vegetation removal, and reseeding, as well as construction, operation, transportation and intercept debris could cause ground disturbances, and therefore could impact geology and soils. Ground disturbances should be assessed for potential impacts such as substantial erosion, siltation, landslides or slumps, soil compaction, or impacts to permafrost areas. In addition, ground disturbances could impact valuable mineral deposits or prime or unique farmland (see Section 3.1.9, Land Use). Off-road vehicle activities for debris recovery or other activities could impact soils as well. The potential for impacts depends upon the geology and topography of the area. Seismic activity within a region of influence should be evaluated and standard measures for seismic safety implemented. For example, construction activities should consider information bearing on seismic design and construction standards, and a design engineer and geotechnical consultant should consider surface faulting potential. Some test activities could impact the stability of seismically active areas. The handling of propellants and other chemicals, as well as launch impacts, should be assessed for potential spills or ground cloud effects of contaminating soils. Best Management

Practices should be identified in the impacts analysis. For example, frequent watering of excavated material and/or use of soil additives to bond exposed surface soils would reduce potential for soil erosion. The analysis also should evaluate the potential for debris craters in impact zones, including impacts to ocean sediment. For test activities, a qualified accident response team would be available near launch locations to minimize any adverse effects from an unlikely event such as flight termination.

Determination of Significance

Actions that would result in uncontrolled soil erosion, uncontrolled contamination of soil, disruption of more than one-acre of permafrost soil, or that would increase the geologic seismic instability of an area would be considered significant.

3.1.7 Hazardous Materials and Hazardous Waste

Definition and Description

Hazardous materials and hazardous waste are defined by a number of U.S. regulatory agencies. In general, hazardous materials and hazardous waste include substances that, because of their quantity, concentration, or physical, chemical, or infectious characteristics, may present substantial danger to the public health, welfare, or the environment when released. The EPA regulates hazardous chemicals, substances, and wastes under the Resource Conservation and Recovery Act (RCRA), the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), and the Toxic Substances Control Act. In addition, the Occupational Safety and Health Administration (OSHA) has definitions and workplace safety-related requirements and thresholds for listed "hazardous and toxic substances,"[37] and the U.S. DOT has definitions and requirements for the safe transport of "hazardous materials."[38]

Hazardous Materials Management

Hazardous materials management is the responsibility of the cognizant authority operating facilities, installations or ranges. Maintenance and flight support operations at various locations may require the use of products containing hazardous materials, including paints, solvents, oils, lubricants, acids, batteries, fuels, surface coatings, and cleaning compounds. These products would be used and stored at appropriate locations throughout each site, but would be primarily associated with industrial and maintenance activities. Site-specific plans would outline the strategies and procedures for storing, handling, and transporting hazardous materials, as well as responding to on-site or off-site spills.

[37] OSHA, 2003
[38] DOT, 2003

Hazardous Waste Management

Federal and state regulations require that hazardous waste be handled, stored, transported, disposed of, or recycled in compliance with applicable regulations. Aircraft and vehicle maintenance, fuel storage and dispensing, and facility and grounds maintenance activities are MDA activity operations that could generate hazardous wastes. The sources of hazardous waste include waste fuel, chemical simulants, laser chemicals, waste oils, spent solvents, paint waste, and used batteries. Site-specific procedures and plans would outline the steps for appropriate management of hazardous wastes, such as satellite accumulation points and properly labeled DOT approved containers. Wastes may be disposed of using designated hazardous waste accumulation facilities or private hazardous waste contractors, as needed.

Impact Assessment

BMDS activities that could involve impacts from hazardous materials transport, disposal, storage, handling, and hazardous waste generation include site preparation and construction, prelaunch, launch/flight, and postlaunch activities and activation of laser weapons, sensors, and C2BMC. Site preparation activities could include exposure to previously contaminated sites. Missile build-out, fueling operations, or construction also may result in the handling of hazardous materials. The analysis should address the use of any ozone-depleting substances, such as refrigerants or foams.

Other toxic, corrosive, or flammable materials that personnel or environmental resources may be exposed to include asbestos, polychlorinated biphenyls, lead-based paint, radon gas, pesticides, petroleum and oils, chemical simulants, and propellants.

Any hazardous waste generated would be disposed of per appropriate state and Federal regulations. Federal military ranges would have established instructions to ensure proper handling and use of hazardous materials. Personnel involved in such operations would be trained in the appropriate procedures to handle hazardous materials and would wear protective clothing and receive specialized training in spill containment and cleanup. Any spills would be handled using established cleanup procedures. All tasks would be performed in accordance with standard operating procedures, and would include provisions for proper handling of hazardous materials/wastes and waste minimization.

Determination of Significance

Actions that would result in uncontrolled generation of hazardous materials or waste, actions that would require hazardous materials and do not have a closure or decommissioning plan, actions that would conflict with existing RCRA or other hazardous material or waste regulations, or actions that would expose the general public, unprotected MDA personnel, or wildlife to hazardous materials or waste that would result

in human or ecological health risk levels greater than 1 x 10^{-6} would be considered significant.

3.1.8 Health and Safety

Definition and Description

Health and safety includes consideration of any activities, occurrences, or operations that have the potential to affect the well being, safety, or health of workers or members of the general public. The primary goal is to identify and prevent accidents or impacts to on-site workers and the general public. In terms of the proposed action and alternatives, safety and health risks would occur primarily from accidents during construction, testing, operation, maintenance, or decommissioning activities. Safety and health risks may also occur from exposure to debris produced during test activities. The health and safety resource area addresses both occupational and environmental health and safety.

Occupational Health and Safety

Occupational health and safety deals with work sites and operational areas where workers would be located. (DOT, 2002) Typical potential hazards and accidents include

- Explosions of flammable liquids, solids, or compressed gases;
- Fires;
- Failures leading to fires or explosions involving boosters or other launch assets;
- Electrocution and burns from electrical equipment and currents;
- EM emissions (radars, lasers, infrared sensing devices);
- Inhalation or dermal exposure to hazardous materials or waste;
- Spills of chemicals and propellants;
- Falling debris related to construction and decommissioning;
- Confined spaces;
- Falls from structures;
- Accidents related to earth moving equipment and power tools; and
- Transportation accidents.

Hazard analyses are performed to identify and assess credible accident scenarios at work sites. The findings of a hazard analysis are used to establish health and safety procedures to prevent accident occurrences and to report and respond to any accidents that do occur.

Environmental Health and Safety

Environmental health and safety considers environmental quality both on and off the work site and operational areas that could impact the human health of the general public. Typical potential hazards and accidents include

- Explosions of flammable liquids, solids, or compressed gases;
- Fires;
- EM emissions (radars, lasers, infrared sensing devices);
- Spills of chemicals or propellants that contaminate surface or ground water;
- Inhalation of hazardous particulate and gaseous materials;
- Chronic/acute exposures to toxic/hazardous materials;
- Failures of electrical grids;
- Falling debris (e.g., from interceptor tests);
- Transportation accidents; and
- Personnel injury and equipment damage due to electrical shock.

Risk assessments are performed to identify, characterize, quantify, and evaluate risks to human health and the environment. A risk assessment considers both the likelihood or probability of occurrence and the consequences of accidents and hazardous events, including catastrophic ones. The results of a risk assessment are used to establish preventative and mitigating measures to reduce the risks to environmental quality and human health. Consideration of risk would also include debris modeling and analysis to determine the potential impact area in the event of a launch failure (including those launches requiring use of an FTS).

Impact Assessment

MDA activities with the potential to impact the health and safety of workers include construction; radar activation, laser weapon activation, missile storage, assembly, and transfer; and launch and post-launch activities. Any debris recovery and emergency operations also could impact worker health and safety. The areas of potential impacts to the health and safety of the public include prelaunch transport of missiles, launches, radar activation, laser activation, and missile flight. The potential impacts of a launch failure should be analyzed. Launch failure could involve an explosion, falling missile debris, release of toxic materials into the air or water, high noise levels, and/or fire.

Handling and assembly of missile components, which are typically accomplished within enclosed buildings, have the potential to affect worker health and safety. Range Commanders Council Standard 321-02 limits the collective risks to 1×10^{-3} for non-mission essential personnel and to 1×10^{-2} for mission essential personnel. If a launch site malfunction occurs, it could result in the scattering of the resulting missile debris anywhere within the LHA. A probabilistic risk analysis would be performed before each flight test to determine that individuals of the general public would not be exposed to a probability of fatality greater than 1 in 10 million for any single mission and 1 in 1 million on an annual basis, as per the Range Commander's Council Standard 321-02. Site-specific environmental documents would identify and, if appropriate, analyze required health and safety regulations for individual sites where activities for the

proposed BMDS may occur. Compliance with Federal, state and local regulations would be required.

Federal military ranges would have specific regulations to ensure the health and safety of members of the range as well as the public in the surrounding area. Applicable safety regulations would be followed in the transport, receipt, storage, and handling of hazardous materials. All shipping would be conducted under DOT regulations. Transportation and loading practices would meet Federal, state, and local regulatory and safety requirements.

Determination of Significance

Actions that would not fall under the existing health and safety operating procedures of the facility or range where such actions would occur, actions that would conflict with existing OSHA regulations, or actions that would result in a level of risk that exceeds the Range Commanders Council Standard 321-02 to the health and safety of the general public and MDA personnel would be considered significant.

3.1.9 Land Use

Definition and Description

Land use is described as the human use of land resources for various purposes, including economic production, natural resource protection, or institutional uses. Land uses frequently are controlled by management plans, policies, ordinances, and regulations that determine the uses that are permissible or protect specially designated or environmentally sensitive areas (e.g., prime farmlands, coastal zones, national parks, historic properties). Planning departments at the local and municipal level typically designate land uses for specific areas, which describe the permitted development activities that are acceptable for the area, such as agricultural, residential, commercial, and industrial.

Public land may be assigned specific designations for which land use and management guidelines are provided. These designations include

- Controlled use or wilderness areas;
- Limited use areas, which protect sensitive, natural, ecological, scenic, and cultural resource values;
- Low intensity regions, which carefully control multiple uses of resources and ensure sensitive values are not significantly diminished;
- Moderate use regions, which provide for a controlled balance between higher intensity uses and resource protection; and
- Intensive use regions, which provide for concentrated use of lands and resources to meet human needs.

Types of land use include agriculture, livestock grazing and production, conservation and recreation sites, military installations, and research sites managed by other agencies and organizations. A particular environment may include cities, towns, and rural communities of all sizes, throughout which are extensive communication systems; industrial complexes with factories and power plants; energy distribution systems for electricity, natural gas, liquid fuels, and nuclear, solar, hydro, and wind power; water treatment facilities; and waste management facilities. Wildlife refuges, national landmarks, and coastal zones present within an environment typically are afforded special status or protection.

A given site for proposed BMDS activities may include launch sites, impact areas, instrumentation sites, facilities, and equipment. On-site land use designations may include flight line zones, test ranges, support service areas, and explosive hazard zones. Land use categories for each site may be defined independently. Differences in terminology for land use classification among facilities where activities for the proposed BMDS may occur can be attributed to the local nature of land use classification, the unique circumstances at a particular facility, or the different interpretations of widely used terms (e.g., industrial, open space). Each land use category depends on a variety of factors, including the level of residual hazards and the risks associated with potential exposures.

The combined efforts of state, county, local, and on-site plans may regulate land use within the boundaries of a particular installation. Facilities where proposed BMDS activities may occur may use a wide range of planning documents as their land use plans, including legal settlement agreements narrowly tailored to designating land uses; comprehensive site plans incorporating all planning information, including current and future land uses, budget projections, and institutional plans; and a hierarchy of multiple planning documents. Wide variation in the level and types of coordination between site personnel and off-site communities regarding land use planning issues may occur. The variation appears to depend on the site's mission, closure schedule, proximity to local off-site development, and level of community interest. On-site land use management plans may address the security of essential mission activities from encroachment and the protection of both human and natural environments.

Impact Assessment

Numerous land use designations may characterize a given environment and the sites located within that environment. As a result, site-specific analysis will identify and, if appropriate, analyze potential impacts to particular land use designations for individual sites where activities for the proposed BMDS may occur. Compliance with Federal and state regulations and local land use plans would be required. Site-specific analysis would be coordinated with the appropriate agencies, including the Bureau of Land Management, National Park Service, U.S. Department of Agriculture Forest Service, and state agencies,

as well as county and municipal planning groups and local communities. At some facilities, it may be necessary to address the issue of encroachment to ensure that off-site development is not encroaching on the site where activities for the proposed BMDS may occur.

Determination of Significance

Actions that would require modification to an existing land use plan of an installation or range, or would preclude existing land use activities at lands adjacent to the action that are not owned by DoD or for which no easement exists between the land owner and the DoD for longer than one week, actions that would disrupt or divide established land use configurations or represent a substantial change in existing land uses, actions that would require the use of other Federal lands where an existing use agreement has not been prepared and authorized by both Federal Agencies, or conflict with existing regulations and policies governing land use (e.g., Coastal Zone Management Act) would be considered significant.

3.1.10 Noise

Definition and Description

Noise is often defined as unwanted or annoying sound that is typically associated with human activity. Most sound is not a single frequency, but rather a mixture of frequencies, with each frequency differing in sound level. The intensities of each frequency combine to generate sound, which usually is measured and expressed in decibels (dB). Decibels are measured on a logarithmic scale, which means that a doubling of sound energy or number of sources producing the same sound level will result in a three dB increase. A 3 dB increase is considered just noticeable to most people, while a 10 dB increase is considered a doubling of perceived loudness.

- **A-weighted decibels (dBA)**. Most measures of noise for community planning purposes use dBA, which are used to characterize noise as heard by the human ear.

- **Community Noise Equivalent Level**. The Community Noise Equivalent Level describes the average sound level during a 24-hour day in dBA. For noises occurring between 7:00 p.m. and 10:00 p.m., five dBA are added to the measured noise level, and for noises occurring between 10:00 p.m. and 7:00 a.m., 10 dBA are added to the measured noise level.

- **Day night average noise level (DNL)**. DNL is the energy average noise level during a 24-hour day. It is reported in dBA and is used to predict human annoyance and community reaction to unwanted sound (noise). Because humans are typically more

sensitive to noise in the evening, the DNL places a 10-dBA penalty on noise produced between the hours of 10:00 p.m. and 7:00 a.m.

- **Equivalent Noise Level (L_{eq})**. The L_{eq} is the energy average A-weighted sound level during a stated measurement period. It is used to describe the time-varying character of environmental noise.

- **Pounds per Square Foot**. Pounds per square foot is a measure of pressure. Some activities of the proposed BMDS may produce pressure waves in the form of sonic booms that can cause damage to eardrums and structures.

Examples of A-weighted noise levels for various common noise sources are shown in Exhibit 3-7.

Exhibit 3-7. Comparative A-Weighted Sound Levels

Noise Level (dBA)	Common Noise Levels	
	Indoor	**Outdoor**
100 – 110	Rock band	Jet flyover at 304 meters (997 feet)
90 – 100	Food blender at one meter (three feet)	Gas lawnmower at one meter (three feet)
80 – 90	Garbage disposal at one meter (three feet)	Diesel truck at 15 meters (49 feet) - Noisy urban daytime
70 – 80	Shouting at one meter (three feet) Vacuum cleaner at three meters (ten feet)	Gas lawnmower at 30 meters (98 feet)
60 – 70	Normal speech at one meter (three feet)	Commercial area heavy traffic at 100 meters (328 feet)
50 – 60	Large business office Dishwasher next room	
40 – 50	Small theater (background) Large conference room (background)	Quiet urban nighttime
30 – 40	Library (background)	Quiet suburban nighttime
20 – 30	Bedroom at night	Quiet rural nighttime
10 – 20	Broadcast/recording studio (background)	
0 – 10	Threshold of hearing	

Source: Modified from FAA, 2001

Noise from transportation sources, such as vehicles and aircraft, and from continuous sources, such as generators, would be assessed using the A-weighted DNL. The A-

weighted DNL significantly reduces the measured pressure level for low-frequency sounds, while slightly increasing the measured pressure level for some high-frequency sounds. Noise from small arms ranges is assessed using the A-weighted DNL. Impulse noise resulting from armor, artillery, and demolition activities is assessed in terms of the C-weighted DNL. The C-weighted DNL is often used to characterize high-energy blast noise and other low frequency sounds capable of inducing vibrations in buildings or other structures. The C-weighted scale does not significantly reduce the measured pressure level for low frequency components of a sound.

Impact Assessment

The acceptability of noise depends in part on expectations associated with land use. An urban environment is noisier than a suburban environment, and a suburban environment is noisier than a rural one. Exhibit 3-8 provides a range of DNL values by land use type.

Exhibit 3-8. Examples of Outdoor Day-Night Average Noise Levels in Various Land Use Locations

Outdoor Location	DNL in dB
Apartment next to freeway	88
¾ mile from touchdown at major airport	86
Downtown with some construction activity	79
Urban high density apartment	78
Urban row housing on major avenue	68
Old urban residential area	59
Wooded residential	51
Agricultural crop land	44
Rural residential	39
Wilderness ambient	35

Source: EPA, 1978

Exhibit 3-9 lists noise measurements that were recorded at some existing facilities where launch activities have taken place, which encompass various environmental settings.

Site-specific analysis would identify and, if appropriate, analyze potential impacts from noise levels at individual sites where activities for the proposed BMDS may occur. Noise impacts resulting from activities associated with the proposed BMDS may include but are not limited to construction activities, missile launches, and use of generators. Three types of receptors are typically analyzed: humans, wildlife, and structures. For each type of receptor, the potential impacts of noise would need to be analyzed in site-specific analyses.

Exhibit 3-9. Range of Noise Measurements

Measurement Locations		Noise Level (dBA)
Remote desert environments[39]		22-38
Interstate interchanges (non-urban)[40]		55-70
Marshall Space Flight Center (wooded area with insects dominating the higher reading)[41]		40-54
Vandenberg AFB[42]		48-67
Edwards AFB (with some areas off base at 80 dBA)[43]		65-85
WSMR[44]	Main post	55-65
	Property boundary	45-55
	Nearby San Andreas National Wildlife Refuge	45
Eastern Range[45]		60-80
KLC[46]	Approximately 1,905 meters (6,250 feet) from center of pad	95
	Distance of 9 to 24 kilometers (5.6 to 15 miles) from the launch pad	70

Source: Modified from DOT, 2001b

Launch Activity Noise

Noise during launch activities would occur due to the rocket engine. Noise generated during launch would result from the interaction of the exhaust jet with the atmosphere and the combustion of the fuel. The sound pressure from a missile is related to the engine's thrust level and other design features. Workers exposed to excessive launch noise would be required to wear hearing protection.

Sonic booms also would be generated during launches when the launch vehicle reached supersonic speed. A sonic boom is a sound that resembles rolling thunder, and is produced by a shock wave that forms at the nose of a vehicle that is traveling faster than

[39] Estimate, no other specifics given
[40] Monitoring data, no other specifics given
[41] One-hour monitoring
[42] Twenty-four hour monitoring

[44] Estimate, no other specifics given
[45] Daytime monitoring
[46] Rocket noise levels from launch of U.S. Air Force atmospheric interceptor technology test vehicles

the speed of sound. The sound heard at the Earth's surface as the "sonic boom" is the sudden onset and release of pressure after the buildup by the shock wave or "peak overpressure."

Construction Noise

In addition to operational noise, construction would result in intermittent, short-term noise effects that would be temporary, lasting for the duration of the noise generating construction activities. Noise-generating construction activities would include excavation and grading, utility construction and paving, and frame building. The specific types of equipment that would be used during construction would be identified in site-specific analyses. Excavation and grading would normally involve the use of bulldozers, scrapers, backhoes, and trucks. The construction of buildings likely would involve the use of pile drivers, concrete mixers, pumps, saws, hammers, cranes, and forklifts.

Power Generation Noise

The use of power generators should not exceed locally regulated noise levels or facility specific noise levels. The noise associated with generators would be controlled by use of standard silencing packages (mufflers) provided by the manufacturer and routine maintenance and inspection of such systems.

<u>Human Response</u>. Noise from single events can be annoying due to noise level, duration of the event, how loud the event is relative to ambient sound levels, and the frequency of occurrence. Additional annoyance can be attributable to a 'startle effect' associated with a sonic boom. Site-specific analysis will identify and, if appropriate, analyze potential impacts from noise levels at individual sites where activities for the proposed BMDS may occur. Compliance with Federal as well as state and local regulations will be required. (EPA, 1978, as referenced in DOT, 2001b)

The annoyance experienced as a result of sonic booms has been widely studied both in the field and in laboratory settings. Annoyance is generally considered to be a function of boom intensity, number of booms per time period, attitude of the population, and the activity in which people were engaged in at the time of the boom. However, there is no precise relationship between the parameters. One study was done to determine the reactions of people routinely exposed to sonic booms (eight sonic booms per day) over a six-month period. This study found that sonic boom annoyance increases as the number and or level of sonic booms increases. (DOT, 2001b) In that study, approximately 20 percent of the population reported annoyance from sonic booms with median peak overpressures of 0.5 psf. Another study suggested that prior experience with sonic booms (such as people who live on an AFB) seems to lower sensitivity to sonic booms. (DOT, 2001b) Other factors that influence the loudness and annoyance are the rise time of the sonic boom and shape of the waveform. (DOT, 2001b) In general, some public

reaction can be expected if occasional sonic booms with peak overpressures between 1.5 and 2 psf impact populated areas (NASA, 1994), but it is possible that at lower amplitudes people can express annoyance to sonic booms. The impacts assessment would include the number, frequency, location, and intensity of sonic booms, and identify affected receptors.

Structural Response. Sonic booms also may cause structural damage, which could impact prehistoric and historic resources. Vibrations from the sonic booms could disturb existing cultural and historic structures, especially those that are not structurally sound. The impacts assessment would identify and evaluate effects on existing cultural resources and historic structures.

Wildlife Response. Responses of wildlife would vary based on the type of noise and its characteristics (amplitude, rise time, duration, frequency content), the species of wildlife, hearing capability, location, habitat type, current activity of the animal, sex and age, previous experience with noise exposure, and condition of the animal. (Manci, 1988) Potential physiological impacts from noise can range from short-term mild impacts, such as an increase in heart rate or small temporary changes in hearing, to more damaging impacts, such as permanent changes in hearing, metabolism, and hormone balance, to long-term severe impacts, such as chronic distress that is harmful to the health of wildlife species and their reproductive fitness. (DOT, 2001b) Potential behavioral impacts from noise also range greatly from minor responses, including small changes in current behavior such as, a “heads up” response, to more severe responses, such as panic and escape flight responses that might result in physiological damage (falling, trampling, crashing, piling). Behavioral responses of wildlife to noise also can accompany physiological responses. The impacts assessment would identify and evaluate effects on affected wildlife, including threatened and endangered species and migratory populations.

Hearing Damage

The OSHA regulation 1910.95 establishes a maximum noise level of 90 dBA for a continuous eight-hour exposure during a working day and higher levels for shorter exposure time in the workplace. The OSHA standards allow for a 5 dBA increase in sound level for a 50 percent reduction in exposure time. Therefore, the maximum noise exposure permitted under the regulation for continuous exposure would be 115 dBA for 15 minutes. (FAA, Aviation Noise Effects, 1985) Other standards have also been recommended for exposure to continuous noise. The EPA has recommended an average L_{eq} of 70 dBA for continuous 24-hour exposure to noise to protect hearing. This level is considered conservative and is based on the probability of negligible hearing loss, defined as less than 5 dB in 100 percent of the exposed population, at the human ear’s most sensitive frequency (4,000 hertz) after a 40-year exposure. (FAA, 1985) Noise also

may be impulsive in nature. Under OSHA regulation 1910.95 exposure to impulse noise should not exceed 140 dBA.

Determination of Significance

Federal and state agencies that regulate noise handle the determination of significant noise impact differently. For example, the FAA considers the threshold of a significant impact to be a 1.5 dBA increase from 65 DNL (FAA Order 1050.1E) Federal Highway Administration (FHWA) does not employ significance thresholds for noise; rather, FHWA uses Noise Abatement Criteria (NAC) where noise abatement is considered (where reasonable and feasible) for EISs as well as EAs. The NAC vary by land use—the residential NAC is 66 dBA, 1 hour L_{eq}. FHWA considers both absolute and relative noise impacts. A relative noise impact refers to the amount of project-related noise increase above ambient noise levels.

Potential BMDS noise impacts could be associated with a wide range of noise sources and noise environments. For example, a generator produces a steady-state noise, with moderate noise levels and limited geographic effect. A missile launch could produce high noise levels for a short duration with little to no exposure in populated areas. Because NEPA requires ‘context and intensity’ in consideration of significant impact, these disparate noise situations potentially call for different definitions of significance. Therefore, the details of what would comprise a ‘significant’ noise impact for the PEIS will be developed and considered on a case-by-case basis.

3.1.11 Socioeconomics

Definition and Description

Socioeconomics is defined as the basic attributes and resources associated with the human environment, in particular population and economic activity. Socioeconomic resources consist of several primary elements including population, employment, and income. Other socioeconomic aspects that are described often may include housing and employment characteristics, and an overview of the local economy.

Impact Assessment

Potential socioeconomic impacts from MDA activities may stem from construction or operation of the BMDS. The magnitude of the impacts would depend on the duration and extent of displacement or modification of existing activities and the diversion or temporary suspension of access. Impact analyses should focus on the following broad areas of economic or social impacts: employment and income; growth inducement; potential impacts to locally significant industries such as tourism, commercial fishing, or

agriculture; displacement of populations, residences, or businesses; and housing or accommodation availability.

Employment and Income

Activities for the proposed BMDS could have a positive economic impact in local communities due to increased jobs in the defense industry. These jobs generally are technology-based and require workers with specialized skills and education. These jobs would contribute to local economies by increasing personal income, thereby increasing the tax base. In addition, an increase in workers in a particular area increases the need for services, which creates more jobs in other industries, such as retail, food services, education, and health.

Local Economies

Additional construction personnel, by spending money in the local economy, mainly via accommodation and procurement of goods and services, would represent both a potential increase in local service-based employment opportunities and a small but positive temporary economic impact to the local community. Site-specific documentation would be required for comprehensive analysis of impacts to local economies.

Displacement Impacts

Some missile defense activities could result in a negative economic impact from displacement of populations, residences or businesses; housing or accommodation availability. For example, health care facilities, housing, and other infrastructure may be insufficient in some areas to support an influx of workers during construction. Testing and operation activities also may require an influx of additional personnel into the area. Proposed activities also could cause displacement of populations during test events and potential impacts to local industries such as tourism, or agriculture due to the closure of these areas during test events. Proposed activities could cause a loss in property value due to adjacent test activities. Site-specific analyses would be required to determine the magnitude of the potential for impact.

Determination of Significance

Significant economic or social impacts do not require preparation of an EIS unless those impacts are combined with significant impacts from other resource categories (see 40 CFR 1504.14). Actions that would disrupt local or regional economies or would displace or introduce a new population that would substantially alter the socioeconomic setting, or actions that would cause a ten percent increase in the risk of crime or other undesirable social factors would be considered significant.

3.1.12 Transportation

Definition and Description

The transportation section addresses ground, air, and marine transport systems.

According to the most recently available data, the U.S. has over four million miles of highways, railroads, and waterways that connect all parts of the country. It also has 19,000 public and private airports and approximately 1.6 trillion miles of oil and gas distribution pipelines. This extensive transportation network supported about 4.9 trillion passenger-miles of travel in 2001 and 3.8 trillion ton-miles of commercial freight shipments in 2001. The U.S. transportation system, one of the world's largest, serves 284 million residents and seven million business establishments. (DOT Bureau of Transportation Statistics [BTS], 2003)

Metropolitan areas are characterized by urban transit, a complex mix of heavy, light, and commuter rail; buses and demand responsive vehicles; ferries; and other less prevalent types such as inclined planes, trolley buses, and automated guide ways. More than one-third of America's population lives outside of urbanized areas, which typically do not have extensive transit systems.

Paved roadways constituted about 65 percent of all highway mileage in 2001. Nearly all of the public roads in U.S. urban areas are paved, however, about half of the miles of rural public roads are unpaved. In 2001, 71 percent of U.S. roads were classified as being in good or very good condition and 14 percent as mediocre or poor. The remaining 15 percent were classified as fair. The generally poorer condition of urban roads, as compared with rural roads, can be attributed to the higher levels of traffic they carry. (DOT BTS, 2003) Urban roads handled about 60 percent of all traffic in 2000 with far fewer miles of road. (DOT BTS, 2001)

The most heavily populated states, California, Texas, Florida, and New York, are the most heavily traveled. However, Wyoming, the least populated state, had the highest vehicle-miles of travel per capita in 2000 at 16,400, followed by Georgia, Alabama, Oklahoma, and New Mexico at over 12,500. The District of Columbia and New York had the lowest vehicle-miles of travel per capita at less than 7,000. (DOT BTS, 2001) Landside access to water ports comprises a system of intermodal rail and truck services. Landside congestion, caused by inadequate control of truck traffic into and out of port terminals combined with the lack of adequate on-dock or near-dock rail access, affects the productivity of U.S. ports and the flow of U.S. international trade. Changes in vessel design impact access to both landside and waterside services. For example, container vessels have increased in size and capacity, which, in turn, drives a need for adequate trans-shipment hub and feeder ports.

Ground Transportation

Ground transportation and traffic circulation refer to the movement of vehicles from origins to destinations through a road and rail network. Roadway operating conditions and the adequacy of the existing and future roadway system to accommodate these vehicular movements usually are described in terms of the volume-to-capacity ratio, which is a comparison of the average daily traffic volume on the roadway to the roadway capacity. The volume-to-capacity ratio corresponds to a Level of Service (LOS) rating, ranging from free-flowing traffic conditions (LOS A) for a volume-to-capacity of usually less than 30 percent of the roadway capacity to forced-flow, congested conditions (LOS F) for a volume-to-capacity of 100 percent of the roadway capacity. LOS A, B, and C are considered good operating conditions where motorists experience minor delays. LOS D represents below average conditions, and LOS E corresponds to the maximum capacity of the roadway. LOS F indicates a congested roadway.

Railway operating conditions and safety standards in the U.S. are regulated by the U.S. DOT, Federal Railroad Administration. The Federal Railroad Administration has established standards for nine types of track (Class 1 through 9); each class has unique construction, maintenance, and inspection standards, as well as operational requirements. Class 1 track is the minimum acceptable standard for general use and has a 16 kilometer per hour (ten mile per hour) speed limit for freight and a 24 kilometer per hour (15 mile per hour) speed limit for passengers. Class 9 track has the most stringent track standards and allows both freight and passenger trains to travel up to 322 kilometers per hour (200 miles per hour). Local regulations, e.g., city speed limits, may reduce speeds regardless of track quality. (DOT, FRA 2002)

Air Transportation

Air transportation refers to the movement of aircraft through airspace. The control of airspace used by air traffic varies from very highly controlled to uncontrolled areas. Examples of highly controlled air traffic situations are flight in the vicinity of airports, where aircraft are in critical phases of flight (take-off and landing), flight under IFR, and flight on the high or low altitude route structure (airways). Less controlled situations include flight VFR or flight outside of U.S. controlled airspace (e.g., flight over international waters off the coast of California, Hawaii, or Alaska).

Marine Transportation

Marine traffic is the transportation of commercial, private, or military vessels at sea, including submarines. Marine traffic flow in congested waters, especially near coastlines, is controlled by the use of directional shipping lanes for large vessels (cargo, container ships, and tankers). Traffic flow controls also are implemented to ensure that harbors and ports-of-entry do not become congested. There is less control on ocean

traffic involving recreational boating, sport fishing, commercial fishing, and activity by naval vessels. However, U.S. Navy vessels follow military procedures and orders (e.g., Fleet Forces Command) as well as Federal, state, and local marine regulations. In most cases, the factors that govern shipping or boating traffic include adequate depth of water, weather conditions (primarily affecting recreational vessels), the availability of fish of recreational or commercial value, and water temperature (higher water temperatures will increase recreational boat traffic and diving activities).

Impact Assessment

General transportation impacts can be assessed by determining the existing traffic flow and LOS. MDA activities that could cause impacts to the LOS include the increased delivery of construction equipment, propellants, or test event equipment, and the influx of construction workers or test operation personnel. In addition, roads, ports, or waterways within the LHA may be closed during test events. Roads also may be closed during the arrival of missile payloads and/or boosters to ensure that roadways near a Range would be vacated.

The region of influence in determining impacts would depend on local traffic volume and transportation infrastructure. At the programmatic level, analysis shows that construction events and associated increases in transport of equipment and personnel are typically short-lived. However, site-specific analyses should be completed to determine local conditions.

Determination of Significance

Actions that are not included as categorical exclusions in DoD's NEPA implementing regulations, or actions that would require the movement of an extremely hazardous, toxic or radiological substance, would generate traffic levels that would require construction of new roadways or expansion of existing roadways, alteration of circulation patterns, or would result in inadequate parking, transportation actions that would result in multi-day disruptions (more than two days) of marine or air traffic shipping lanes would be considered significant. In addition, actions that would result in road closures for more than two days or closures of major highways for more than one hour during peak traffic hours would be considered significant.

3.1.13 Utilities

Definition and Description

The purpose of the utilities section is to address the existing rate of consumption, generation, and distribution of utilities, which include energy, water, wastewater, and solid waste and construction debris. This section address those facilities and systems that

provide power, water, wastewater treatment, the collection and disposal of solid waste, and other utility services.

- **Energy**. Energy refers to the power that is produced by a central electrical power plant or, in some cases, by individual power generators. The power would be utilized for both construction and operational activities on different sites.

- **Water**. Water refers to the system that produces water, the treatment system that purifies the water, and the network that distributes that water. This water system usually is controlled, managed, and distributed by an entity such as a utility purveyor. In the absence of a water system, individualized water wells or a series of wells meet the demand for water. The water system is identified by potable, or drinkable, freshwater and nonpotable water used for other activities such as construction, operations, and irrigation. In some cases the non-potable system is saltwater. The water system is composed of a source that produces the water and the treatment systems that cleanse and purify it, making it available for use. Water made available to the public must meet EPA standards as described in Section 3.1.15.

- **Wastewater**. There are different methods of treating wastewater that is produced by a site. Wastewater can be collected in a central system and then directed to a treatment plant where it can be treated and then discharged. In many instances, the wastewater is further treated and reclaimed for use as nonpotable water. In the absence of a central system, septic systems collect and treat water either individually (individual households) or collectively (within a community).

- **Solid Waste**. Solid waste disposal includes the collection, handling, and disposal of waste. Designated landfills within an area or region are the final destinations where solid waste and construction debris is transported for processing. Solid waste usually is processed to separate out recyclable products first. Solid waste disposal also includes practices such as open burning, septage disposal, and burial in open or excavated trenches, where allowed by law.

Impact Assessment

A site-specific impact assessment should consider whether there is adequate wastewater treatment capacity or capability and if the proposed action would exceed wastewater treatment requirements and alter the existing rate of consumption, generation, and distribution of utilities. An impact analysis should include an evaluation of waste disposal facilities and landfills and waste discharge requirements. MDA activities require consistent power sources, and depletion of an existing power supply from a central electric power plant or individual power generators should be considered. Assessment of potential impacts on utilities would include a review and analysis of

- Wastewater treatment requirements of the applicable Regional Water Quality Control Board or other governing authority;
- Availability of sufficient water supplies to serve the proposed action, or need for new or expanded entitlements;
- Availability of waste disposal facilities and landfills with sufficient permitted capacity to accommodate solid waste disposal needs;
- International treaties and Federal, state, and local statutes and regulations related to solid waste; and
- Capacity of the existing power supply providers and wastewater treatment providers to determine whether they could adequately serve the projected demand of the proposed action, in addition to the provider's existing commitments.

Determination of impacts on utilities also would include consideration of whether the proposed action would require or result in the construction of new water or wastewater treatment facilities, new storm water drainage facilities, or energy sources beyond permitted levels. Construction of new facilities or expansion of existing facilities has the potential to cause significant environmental impacts. It would be necessary to obtain appropriate permits for activities that may impact utility systems and facilities and to ensure compliance with local laws and regulations.

Site-specific analysis would be required to identify and, if appropriate, analyze potential impacts to a local utility system for individual activities for the proposed BMDS. For this reason, this PEIS will not include an analysis of the proposed BMDS activities' impacts on utilities.

Determination of Significance

Actions that would result in exceeding the existing capacity of the regional utility service providers (water supply, wastewater disposal, electricity, natural gas, solid waste disposal) and would require the identification or development of new utilities, supplies (water, electricity, natural gas), or disposal facilities (wastewater treatment facilities or solid waste disposal facilities) and their associated utility transmission corridors would be considered significant.

3.1.14 Visual Resources

Definition and Description

Visual resources are defined as the natural and man-made features that constitute the aesthetic qualities of an area. Landforms, surface water, vegetation, and man-made features are the fundamental characteristics of an area that define the visual environment and form the overall impression that an observer receives of an area. The importance of visual resources and any changes in the visual character of an area is influenced by social

considerations, including the public value placed on the area, public awareness of the area, and community concern for the visual resources in the area.

The visual resources of an area and any proposed changes to these resources can be evaluated in terms of "visual dominance" and "visual sensitivity." Visual dominance describes the level of noticeability that occurs as the result of a visual change in an area. The levels of visual dominance vary from "not noticeable" to a significant change that demands attention and cannot be disregarded. Visual sensitivity depends on the setting of an area. Areas such as coastlines, national parks, and recreation or wilderness areas usually are considered to have high visual sensitivity, whereas heavily industrialized urban areas tend to have the lowest visual sensitivity.

The significance of visual effects is very subjective and depends upon the degree of alteration, the scenic quality of the area disturbed, and the sensitivity of the viewers. The degree of alteration refers to the height and depth of maximum cut and fill areas and the introduction of urban elements into an existing natural environment or a substantial increase of structural elements into an already urban environment, while acknowledging any unique topographical formation or natural landmark. Sensitive viewers are those who utilize the outdoor environment or value a scenic viewpoint to enhance their daily activity and are typically residents or recreation users. Changes in the existing landscape where there are no identified scenic values or sensitive viewers are considered less than significant. Also, it is possible to acknowledge a visual change as possibly adverse but not significant, because either viewers are not sensitive or the surrounding scenic quality is not high. Visual impacts also would occur if proposed development is inconsistent with existing goals and policies of jurisdictions in which the project is located.

Many environments are likely to include regions of rich aesthetic and visual resources as well as designated and undesignated natural areas of great beauty and scenic diversity. Visual resources may fall under several different designations including national forest; national monument; national, state, and county parkland; national wildlife refuges; wilderness areas; wild and scenic rivers; national trails; and privately owned land. Various roads also may be designated scenic byways due to their scenic, historic, and cultural qualities. Visually sensitive recreational areas or scenic highways may be located in close vicinity of a site where activities for the proposed BMDS may occur.

Installations where MDA activities for the proposed BMDS may occur are typically dominated by developed, high technology buildings and support facilities. Some existing military sites are relatively unobtrusive when viewed from surrounding areas; however, it is possible that a variety of visual and aesthetic resources may be located near sites where activities for the proposed BMDS may occur.

Impact Assessment

MDA activities could have aesthetic impacts associated with changes in either the built or natural environment. An impacts analysis should include the length of visual disturbance (short- or long-term).

Assessment of potential impacts on visual resources should include a review and analysis of

- Short-term visual impacts such as the presence of heavy machinery during construction of a project (large trucks, cranes, and other construction equipment would be visible within the construction zone and in surrounding areas only during the construction phase.);
- Long-term visual changes such as those associated with altering the existing visual environment by constructing buildings, including those with high vertical profiles;
- Existing scenic resource, including but not limited to trees, rock outcroppings, and historic buildings within a state scenic highway;
- Existing visual character or quality of a site and its surroundings;
- New sources of substantial light or glare, which could adversely affect day or nighttime views in the area (for example, nighttime lighting, particularly during construction can cause impacts to visual resources);
- Viewer concern, or the level of scenic importance based on expressed human concern for the scenic quality of land;
- Distance an area can be seen by observers and the degree of visible detail within that area; and
- Extent of modification that would occur as a result of the proposed action.

Numerous visual and aesthetic resources may be identified in a given environment and at or near BMDS installations located within that environment. As a result, site-specific environmental documentation will identify and, if appropriate, analyze potential impacts to visual and aesthetic resources located in the vicinity of sites where activities for the proposed BMDS may occur. For this reason, this PEIS will not include an analysis of the proposed BMDS activities' impacts on visual resources.

Determination of Significance

Actions that would be considered significant include those that involve structures or land alterations that are visually incompatible with or obtrusive to the existing visual setting and landscape, noticeably increase visual contrast and reduce the scenic quality rating, permanently block or disrupt existing views or reduce public opportunities to view scenic resources, or conflict with existing regulations and policies governing aesthetics and visual resources (e.g., National Historic Preservation Act).

3.1.15 Water Resources

Definition and Description

Water resources include surface water, ground water, and floodplains. Surface water resources consist of lakes, rivers, and streams. Surface water is important for its contributions to the economic, ecological, recreational, and human health of a community or locale. Storm water flows, which may be exacerbated by high proportions of impervious surfaces (e.g., buildings, roads, and parking lots), are important to the management of surface water. Storm water also is important to surface water quality because of its potential to introduce sediments and other contaminants into lakes, rivers, and streams.

Ground water consists of the subsurface hydrologic resources. It is an essential resource often used for potable water consumption, agricultural irrigation, and industrial applications. Ground water typically may be described in terms of its depth from the surface, aquifer or well capacity, water quality, surrounding geologic composition, and recharge rate.

Floodplains are areas of low-lying ground along a river or stream channel. Such lands may be subject to periodic or infrequent inundation due to rain or melting snow. Risk of flooding depends on topography, the frequency of precipitation events, and the size of the watershed above the floodplain. Often development in floodplains is limited to passive uses, such as recreational and preservation activities, to reduce the risks to human health and safety.

The National Water Quality Inventory summarizes the water quality assessments performed by state, local and Tribal governments. (EPA, 2000) Water quality standards consist of three elements: (1) designated uses assigned to water body (e.g., drinking, swimming, and fishing); (2) criteria to protect the designated use (e.g., chemical specific threshold limits); and (3) anti-degradation policy to prevent deterioration of current water quality. The status of the U.S. water quality in 2000 is described in Exhibit 3-10.

Exhibit 3-10. Summary of Quality of Assessed Rivers, Lakes, and Estuaries

Water Body Type	Total Size, approximate	Amount Assessed* (Percent of Total)	Good (Percent of Assessed)	Good but Threatened (Percent of Assessed)	Polluted (Percent of Assessed)
Rivers, kilometers [miles]	5.94 million (3.7 million)	19 percent	52 percent	98 percent	38 percent
Lakes, hectares [acres]	16.4 million (40.6 million)	43 percent	46 percent	8 percent	44 percent
Estuaries, square kilometers [square miles]	22,630 (87,370)	36 percent	45 percent	<43 percent	50 percent

Source: EPA, 2002
*Includes water bodies assessed as not attainable for one or more uses
Note: percentages may not add up to 100 percent due to rounding

The leading causes of impairment of rivers and streams include pathogens (bacteria), siltation (sedimentation), and habitat alterations, and the leading sources for these include agriculture, hydraulic modifications, and habitat modifications. The leading causes of impairment of lakes, ponds and reservoirs include nutrients, metals (primarily mercury), and siltation (sedimentation), and the leading sources for these include agriculture, hydraulic modifications, and urban runoff/storm sewers. The leading causes of impairment of estuaries include metals (primarily mercury), pesticides, and oxygen-depleting substances, and the leading sources for these include municipal point sources, urban runoff/storm sewers, and industrial discharges. (EPA, 2002)

Impact Assessment

MDA activities that could impact water resources include those that either alter the flow of surface water, supply of ground water, or in some way contribute foreign bodies (pollution, sediment) to these water resources.

Assessment of potential impacts on water quantity would include a review and analysis of activities that

- Increase the number of impervious surfaces in an environment such as construction of new roads, buildings, parking lots, launch pads or runways (these surfaces can impact storm water runoff and recharge of ground water sources); and

- Consume ground water or surface water for a particular facility (the availability of water resources varies between locations).

Assessment of potential impacts on water quality would also include a review and analysis of activities that result in emissions or discharge of pollutants to water resources such as

- Construction or operation activities that could contribute to the sedimentation of water bodies; and
- Causes of point and non-point source pollution such as transportation emissions and ground clouds from launch, runoff of deluge or wash down water, thermal discharges, debris impacts, and any plans for open burning/open detonation.

Individual construction projects and associated water demands cannot be considered at the programmatic level, but must be analyzed in site-specific environmental documentation that can assess the impacts of such activities. This PEIS addresses the general impacts of BMDS activities resulting in sedimentation and pollution on water resources.

Determination of Significance

Actions that would fill in jurisdictional wetlands at levels that exceed the criteria for a Nationwide Permit and would require consultation with the U.S. Army Corps of Engineers and the development and implementation of a mitigation plan would be considered significant. Actions that would violate or exceed existing National Discharge Elimination System or Total Maximum Daily Load standards or would degrade the Total Maximum Daily Load classification of a water body, or would violate existing international, Federal, or state water discharge treaties or regulations would be considered significant. Actions that occur within and do not comply with a state wellhead protection area and its management practices, a state coastal zone management program, or any new ground water or surface water extraction system that would affect the water table or flow rates that has not been coordinated with the appropriate regulatory agency would be considered significant.

3.2 Affected Environment

The Affected Environment discussion describes the particular characteristics of each resource area[47] within nine terrestrial biomes, the BOA, and the Atmosphere, which represent the land, air (atmosphere), water, and space environments where proposed BMDS activities are reasonably foreseeable. Each contains distinct plant and animal groups and political boundaries.

---

[47] Cultural resources, environmental justice, land use, socioeconomics, utilities and visual resources are not discussed in the biome descriptions because they are local in nature and are not analyzed in Chapter 4.

A biome is a large geographical area of distinctive plant and animal groups. The climate and geography of an area determine what type of biome can exist in that area. Major terrestrial biomes include deserts, forests, grasslands, mountains, tundra and associated surface water bodies. Major marine systems include intertidal zones (which include sandy beaches, rocks, estuaries, mangrove swamps and coral reefs), neritic zones (the relatively shallow ocean that extends to the edge of the continental shelf, where primary productivity depends on planktonic algae growing as deep as the light can reach), oceanic zones, and abyssal plains.

Detailed descriptions of the nine terrestrial biomes, the BOA, and the Atmosphere as addressed in this PEIS are found in Appendix H Biome Descriptions.

3.2.1 Arctic Tundra Biome

The Arctic Tundra Biome[48] discussion encompasses the arctic coastal regions that border the North Atlantic Ocean and Arctic Ocean. This biome includes coastal portions of the state of Alaska in the U.S., Canada, and Greenland (administered by Denmark). The global distribution of this biome is depicted in Exhibit 3-11.

The majority of the Arctic Tundra Biome is located north of the latitudinal tree line and consists of the northern continental fringes of North America from approximately the Arctic Circle northward. For example, Thule AFB, Greenland, which is located approximately 1,100 kilometers (700 miles) north of the Arctic Circle, is the northernmost installation where MDA activities for the proposed BMDS may occur. The Arctic Tundra Biome includes other coastal locations that may be situated south of the Arctic Circle but have a climate and ecosystem similar to that of inland Arctic Tundra. These sites are located on the islands of the Aleutian chain and include Eareckson Air Station, Shemya Island, Alaska, and Port of Adak, Adak, Alaska.

[48] Exhibit 3-11 shows the global location of the Arctic Tundra ecosystem. However, based on reasonably foreseeable locations for activities for the proposed BMDS to occur, the Affected Environment focuses on the coastal portions of this ecosystem.

Exhibit 3-11. Global Distribution of the Arctic Tundra Biome

Source: Modified from National Geographic, 2003a

3.2.1.1 Air Quality

The climate of the Arctic Tundra Biome is characterized as polar maritime with persistent overcast skies, high winds, frequent and often violent storms, and a narrow range of temperature fluctuation throughout the year. The average annual temperature is -28°Celsius (^{o}C) (-18°Fahrenheit [^{o}F]). Parts of the Arctic Tundra may be classified as desert due to low precipitation. Annual precipitation is light, often less than 200 millimeters (eight inches). Most precipitation falls as snow in October through November. However, because potential evaporation also is very low, the climate tends to be humid. The Arctic Tundra also is characterized by high winds, which can blow between 48 to 97 kilometers (30 to 60 miles) per hour.

Air quality in the Arctic Tundra Biome is considered good, however, some areas in and around urban centers are in non-attainment for CO.

3.2.1.2 Airspace

Airspace above U.S. military airfields in the Arctic Tundra Biome includes controlled airspace and operates under IFR. The Arctic Tundra Biome also includes regions that are located in international airspace and therefore, the procedures of the International Civil Aviation Organization (ICAO) are followed. Much of Alaska's aviation activity takes

place within existing MOAs, through a shared-use agreement, with information provided by the Special Use Airspace Information Service, which is a system operated by the U.S. Air Force under agreement with the FAA Alaskan Region to assist pilots with flight planning and situational awareness while operating in or around MOAs or Restricted Areas in interior Alaska. In Canada, the Air Navigation Services and Airspace Services of Transport Canada are responsible for issues involved with airspace utilization and classification, levels of service for Air Navigation Service facilities, and services, including weather, navigation, radar, and communication services. In Greenland, the Danish Civil Aviation Administration issues Notices to Airmen (NOTAMs) regarding restricted airspace.

Civilian, military, and private airports exist in the Arctic Tundra Biome. Civilian aircrafts generally fly along established flight corridors that operate under VFR.

3.2.1.3 Biological Resources

Tundra environments are characterized by treeless areas, which consist of dwarfed shrubs and miniature wildflowers adapted to a short growing season. Species resident in arctic tundra have evolved adaptations peculiar to high latitudes. Examples of land mammals found on the Arctic Tundra include shrews, hares, rodents, wolves, foxes, bears and deer. Several lakes in the Arctic Tundra region support a small, unique assemblage of freshwater fishes.

Wetlands are typical of the Arctic Tundra. Ecological reserves and wildlife refuges are found throughout the Arctic Tundra region. Disturbance caused by boats or aircraft usually is controlled by distance or altitude regulations in protected areas and advisory restrictions elsewhere. Sometimes boat activities, such as the use of horns, are restricted. Exhibit 3-12 gives distance/altitude restrictions currently in place in Arctic countries. Canada, Finland, Greenland, Russia, and the U.S. restrict the distance boats can approach breeding seabirds, but restrictions apply only to specific protected areas. Distance restrictions range from 15 meters (49 feet) for unmotorized boats in some reserves within Newfoundland, Canada, to 1,600 meters (5,250 feet) in reserves in the U.S.

Arctic countries restrict the altitude below which aircraft cannot fly over a seabird colony. In general, minimum altitudes are in the range of 300-500 meters (984 to 1,640 feet) but are higher over some reserves in the U.S. (700 meters [2,300 feet]). Canadian flight manuals advise a minimum altitude of over 600 meters (1,970 feet) when flying over bird concentrations. In Greenland, advisory rules are in place restricting disturbance to wildlife caused by mineral resource exploration and extraction (directed mainly at helicopters).

Exhibit 3-12. Regulated Activities Near Seabird Colonies in Arctic Regions

Country	Boat Distance (closest approach)	Boat Speed (maximum)	Aircraft Altitude (minimum)	Use of Boat Siren
Canada	20 meters (66 feet) – motorized[1] 15 meters (49 feet) – non-motorized 100 meters (328 feet) or 50 meters (164 feet) off murre colonies	--	300 meters (984 feet) April 1 – September 1 in Newfoundland province reserves, most large colonies are marked on aeronautical charts	Not explicitly restricted but not allowed if disturbance to colony occurs
Greenland	500 meters (1,640 feet) for some protected colonies	18 kilometers per hour (11 miles per hour)[2]	500 meters (1,640 feet)	--
U.S.	100 – 1,600 meters (328 – 5,250 feet)	--	500 – 700 meters (1,640 – 2,300 feet)	--

Source: Modified from Chardine and Mendenhall, 2003
[1]Provincial regulation; Gull Island, Witless Bay- mixed Atlantic Puffin, Black-legged Kittiwake, Common Murre colony. Boat tour operators presently exempt.
[2]Restriction in place for mineral exploration activities only

3.2.1.4 Geology and Soils

Under a protective layer of sod, water in the soil melts in summer to produce a thick mud that sometimes flows downslope to create bulges, terraces, and lobes on hillsides. The freeze and thaw of water in the soil sorts out coarse particles, giving rise to such patterns in the ground as rings, polygons, and stripes made of stones. The coastal plains have numerous lakes of thermokarst origin, formed by melting ground water.

Soil particles in the Arctic Tundra derive almost entirely from mechanical breakup of rock, with little or no chemical alteration. Continual freezing and thawing of the soil have disintegrated its particles. In the Arctic Tundra, the soil is very low in nutrients and minerals, except where animal droppings fertilize the soil. (Bailey, 1995) Below the soil is the tundra's permafrost, a permanently frozen layer of earth. The majority of the Arctic Tundra Biome resides on a layer of permafrost.

Geologic hazards in the Arctic Tundra Biome include earthquakes, volcanic activity, and avalanches.

3.2.1.5 Hazardous Materials and Hazardous Waste

Installations where MDA activities for the proposed BMDS may occur may store and use large quantities of hazardous materials, including a variety of flammable and combustible liquids. Procedures that comply with applicable laws and regulations for managing hazardous materials are developed to establish standard operating procedures for the correct management and storage of hazardous materials at installations. Due to the extreme climate, special measures may be necessary for storage and handling of hazardous materials in arctic areas.

Wastes generated by facilities that may be used for the proposed BMDS include oils, fuels, antifreeze, paint, paint thinner and remover, photo chemicals, pesticides, aerosol canisters, batteries, used acetone, sulfuric acid, and sewage sludge. Procedures that comply with applicable laws and regulations are developed for managing hazardous wastes at sites where activities for the proposed BMDS may occur.

3.2.1.6 Health and Safety

All activities associated with the proposed BMDS would comply with Federal, state, and local laws and regulations applicable to worker and environmental health and safety. The MDA would take every reasonable precaution during the planning and execution of the operations, training exercises, and test and development activities to prevent injury to human life or property. Health and safety procedures should be included in site-specific operating documents.

3.2.1.7 Noise

The principal sources of noise from missile defense operations are vehicular traffic and military activities, including aircraft operations, rocket testing, and rocket launches. Frequency and duration of noise from military activities vary as a factor of the irregular training schedules, and noise levels vary with the type of activities at these facilities. Sonic booms may be produced as a result of BMDS activities. Other sources of noise would result from construction activities. Measurements of ambient sound levels should be analyzed in site-specific environmental documents.

3.2.1.8 Transportation

Roadway travel in the Arctic Tundra Biome is generally limited due to the lack of roads in the vast, undeveloped terrain. The summer months experience the highest amount of traffic, due to tourism and good weather. The Arctic Tundra Biome includes railway systems that provide freight, passenger, and intermodal transportation across North America, as well as regional and local service railways. Given the vast area of the Arctic Tundra Biome and the limited road network, aircraft provide an alternate means of

transportation. Marine travel tends to be limited in the Arctic Tundra Biome due to glacial patches found throughout many waterways.

3.2.1.9 Water Resources

In the Arctic Tundra, alluvial deposits are the principal aquifers for ground water, which is greatly restricted by permafrost. During the summer when snow melts, the water percolates through the active layer but is unable to penetrate the permafrost. Pools of water form on the surface, and the active layer becomes saturated. Surface waters in the Arctic Tundra tend to be acidic and rich in organic material.

Surface water and ground water quality is generally good in the Arctic Tundra Biome except in isolated areas of known contamination. Although soils in the Arctic Tundra Biome are strongly acidic, pH of regional surface waters in North America is around 7, ranging from 6.8 to 7.5 in streams and 7.1 to 7.3 in lakes. The relatively high pH and capacity of streams and lakes to buffer acid inputs from natural and man-made sources are presumed to be the result of ions (e.g., calcium and magnesium) that have been carried into the atmosphere with sea spray and subsequently returned in rainfall. This is a common occurrence in coastal maritime regions. (Wetzel 1975, as referenced in FAA, 1996)

3.2.2 Sub-Arctic Taiga Biome

The Sub-Arctic Taiga Biome discussion focuses on the sub-arctic regions of North America, including portions of the state of Alaska. This biome is generally located between latitudes 50 and 60 degrees north (see Exhibit 3-13). The sub-arctic climate zone coincides with a great belt of needleleaf forest, often referred to as boreal forest, and with the open lichen woodland known as taiga. Existing inland sites found in Alaska in the Sub-Arctic Taiga Biome include Fort Greely (which includes Delta Junction), Clear Air Force Station, Eielson AFB, and Poker Flat Research Range.

Exhibit 3-13. Global Distribution of the Sub-Arctic Taiga Biome

Source: Modified From National Geographic, 2003b

Coastal sites also are located in the Sub-Arctic Taiga Biome, including portions of southwestern and western Alaska. Coastal sites are influenced by the cool climate generated by the cold waters of the North Atlantic Ocean and share maritime characteristics. Existing coastal sites where proposed BMDS activities may occur are found in Alaska in the Sub-Arctic Taiga Biome and include the KLC and the Port of Valdez.

3.2.2.1 Air Quality

The average temperature is below freezing for six months out of the year. Winter is the dominant season and the temperature range is -54^{o}C to -1°C (-65°F to 30°F). Summers are mostly rainy, and humid, and temperatures range from –7°C to 21°C (20°F to 70°F). The total precipitation in a year is 30 to 85 centimeters (12 to 33 inches), which may fall as rain or snow or accumulate as dew. Surface winds along the coast are much stronger and more persistent than at inland areas.

Air quality in the Sub-Arctic Taiga Biome generally is considered favorable; however, some areas in and around urban centers, such as Anchorage and Fairbanks are in non-attainment for CO concentrations. These urban centers typically exceed CO NAAQS only during the winter (October through March).

Emissions from activities for the proposed BMDS include CO, NO_X, SO_X, VOCs, HAPs, and PM. In coastal areas, wind-blown volcanic dust is the primary air contaminant.

3.2.2.2 Airspace

Airspace above U.S. military airfields in the Sub-Arctic Taiga Biome generally includes controlled airspace and operates under IFR.

Much of Alaska's aviation activity takes place within existing MOAs, through a shared-use agreement, with information provided by the Special Use Airspace Information Service, which is a system operated by the U.S. Air Force under agreement with the FAA Alaskan Region to assist pilots with flight planning and situational awareness while operating in or around MOAs or Restricted Areas in interior Alaska.

There are approximately 600 civilian, military, and private airports and more than 3,000 airstrips in the state of Alaska. Existing military airfields, with runways that are paved and in good condition, would be used to support activities for the proposed BMDS.

Civilian aircraft generally fly along established flight corridors that operate under VFR.

3.2.2.3 Biological Resources

The vegetation of the Sub-Arctic Taiga Biome is primarily boreal forest, which is a complex array of plant communities shaped by fire, soil temperature, drainage, and exposure.

The interior areas of the Sub-Arctic Taiga Biome are populated with many animals that have evolved to meet conditions found at higher latitudes. All estuarine and marine areas out to the exclusive economic zone (322 kilometers [200 miles] from the coast) of the U.S. used by Alaskan Pacific salmon are designated as Essential Fish Habitat for salmon fisheries. Essential Fish Habitat also has been designated for scallops and Gulf of Alaska ground fish in the Port of Valdez. (U.S. Army Space and Missile Defense Command, 2003)

Most wetlands in the Sub-Arctic Taiga generally are classified as palustrine (non-flowing) or riverine, which occur alongside rivers and streams. On most wetlands in the sub-arctic region, wet soils result from a variety of sources, including the late melt of snow over either impervious subsoil layers such as glacial silts or discontinuous permafrost.

3.2.2.4 Geology and Soils

High mountains, broad lowlands, diverse streams and lakes, and complex rock formations characterize the geology of the Sub-Arctic Taiga Biome.

The boreal forest grows on poorly developed soils with pockets of wet, organic histosols. These light gray soils are wet, strongly leached, and acidic; they form a highly distinct layer beneath a topsoil layer of organic matter. Soils in the coastal areas are typically rocky, organic, or volcanic. The maritime taiga is characterized by poor drainage of surface water.

Geologic hazards in the Sub-Arctic Taiga Biome include earthquakes, volcanic activity, and avalanches.

3.2.2.5 Hazardous Materials and Hazardous Waste

Hazardous materials and hazardous waste in the Sub-Arctic Taiga Biome are similar to those found in the Arctic Tundra Biome described in Section 3.2.1.5.

3.2.2.6 Health and Safety

Health and Safety attributes of the Sub-Arctic Taiga Biome are similar to those discussed in Section 3.2.1.6.

3.2.2.7 Noise

The Sub-Arctic Taiga Biome generally is sparsely populated and most of the region is expected to have a background noise level of DNL less than or equal to 55 dBA.

3.2.2.8 Transportation

Transportation attributes of the Sub-Arctic Taiga Biome are similar to those discussed in Section 3.2.1.8.

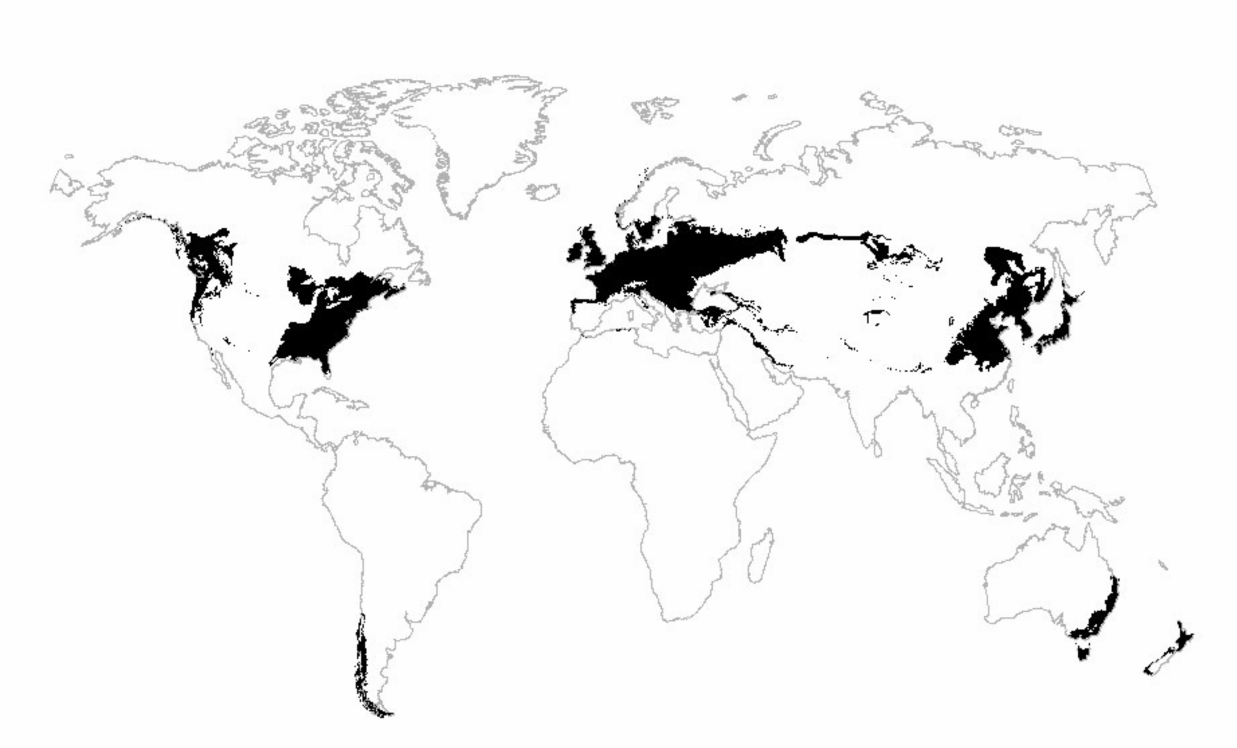
3.2.2.9 Water Resources

Ground water is supplied by rivers, precipitation, and melt water in the Sub-Arctic Taiga Biome. Characteristic of the taiga are innumerable water bodies, including bogs, fens, marshes, shallow lakes, rivers and wetlands, which are intermixed among the forest and hold vast amounts of water. In coastal areas, ground water is found primarily in river basins and recharged by infiltration of melt water from precipitation and glaciers. Water quality is subject to seasonal variations, but remains within established EPA drinking water standards.

3.2.3 Deciduous Forest Biome

As shown in Exhibit 3-14, the Deciduous Forest Biome includes the deciduous forest regions of North America, which include most of the eastern portion of the U.S. and parts of central Europe and East Asia. The description in this section of the U.S. deciduous forest is representative of this biome throughout the world.

Exhibit 3-14. Global Distribution of the Deciduous Forest Biome



Source: Modified From National Geographic, 2003b

Existing inland sites in the Deciduous Forest Biome include Redstone Arsenal, Alabama; Fort Devens, Massachusetts; and Aberdeen Proving Ground, Maryland.

Coastal sites also are located in the Deciduous Forest Biome. These sites share maritime characteristics. Existing coastal sites include Naval Air Station Patuxent River, Maryland; Wallops Island, Virginia; Cape Canaveral Air Force Station, Florida; Cape Cod Air Force Station, Massachusetts; and Eglin AFB, Florida.

3.2.3.1 Air Quality

The average annual temperature in a deciduous forest is 10°C (50°F). The average rainfall is 76 to 152 centimeters (30 to 60 inches) a year, with nearly 36 centimeters (14 inches) of rain in the winter and more than 46 centimeters (18 inches) of rain in the

summer. Humidity in these forests is high, ranging from 60 to 80 percent. Because of its location, air masses from both the cold polar region and the warm tropical region contribute to the climate changes in this biome.

Many metropolitan regions on the U.S. Atlantic Coast are in non-attainment for EPA's NAAQS for ozone, the primary constituent of urban smog. The southern Atlantic coast from Virginia through Florida is in attainment for all criteria air pollutants. However, the entire coastal area from northern Virginia through Maine is in non-attainment for ozone (ranging from moderate to severe), and small areas in Connecticut are in moderate non-attainment for PM_{10}.

Emissions from activities for the proposed BMDS include CO, NO_X, SO_X, VOCs, HAPs, and PM. Existing emissions sources in the coastal areas of the Deciduous Forest Biome are primarily the same as for those in the inland areas.

3.2.3.2 Airspace

The Deciduous Forest Biome in the U.S. contains all FAA classifications for airspace, as described in Section 3.1.2.

3.2.3.3 Biological Resources

On numerous sites where activities for the proposed BMDS may occur, native vegetation has been removed, and the land is landscaped and maintained by mowing and brush control measures. Isolated pockets of vegetation may remain on sites where activities for the proposed BMDS may occur, however, vegetation on off-site areas is widespread and may be undisturbed.

The Deciduous Forest Biome provides habitat for a wide variety of animals. State and federally endangered and threatened species in the biome include but are not limited to red-cockaded woodpeckers and the northeastern tiger beetle.

The Florida Keys have been designated a National Marine Sanctuary, Outstanding Florida Waters, and an Area of Critical State Concern. In addition, the Deciduous Forest Biome includes critical habitat. For example, critical habitat for the Northern Right whale (*Eubalaena glacialis*) is designated for portions of Cape Cod Bay and Stellwagen Bank, the Great South Channel (each off the coast of Massachusetts) and waters adjacent to the coasts of Georgia and the east coast of Florida.

3.2.3.4 Geology and Soils

The geology of the Deciduous Forest inland is varied and consists of low mountains and plateaus. The Coastal Plain is predominantly flat and is covered with terrestrial sediments.

There are two types of soil found in deciduous forests in the U.S. Fertile soils with high organic content are rich in nutrients and have well-developed layers of clay. The second type, the “red clay” soils are found in humid temperate and tropical areas of the world, typically on older, stable landscapes. In coastal areas of this biome, soils are predominantly deep and adequately drained.

Because limited seismic activity occurs along the Atlantic continental shelf, the risk of an earthquake in the Deciduous Forest Biome is low. Volcanic activity generally is not observed along the U.S. Atlantic and Gulf Coasts, however, cracks present in the Eastern Seaboard have the potential to cause the seabed to crumble and create a tsunami that would push huge masses of sea water toward the coast. Landslides are a significant geologic hazard throughout the Deciduous Forest Biome.

3.2.3.5 Hazardous Materials and Hazardous Waste

Hazardous materials and hazardous waste attributes of the Deciduous Forest Biome are similar to those discussed in Section 3.2.1.5. Except the moderate climate characteristic of the Deciduous Forest Biome does not require special consideration as is necessary in the extreme temperatures of the Arctic Tundra Biome.

3.2.3.6 Health and Safety

Health and Safety attributes of the Deciduous Forest Biome are similar to those discussed in Section 3.2.1.6.

3.2.3.7 Noise

The Eastern Range is a representative example of noise levels for sites where activities for the proposed BMDS may occur in the Deciduous Forest Biome. Ambient noise levels based on daytime monitoring, range from 60 dBA to 80 dBA. (DOT, 2001) Noise sources associated with the proposed BMDS are similar to those described in Section 3.2.1.7.

3.2.3.8 Transportation

The Deciduous Forest Biome includes both coastal and inland regions that sustain widespread infrastructure, including marine ports and docks that are supported by traffic

circulation systems such as highways and byways, unpaved roads, non-maintained roads, trails, railroad lines, municipal, private, and military airports and any other system involved in mass transportation.

On-site roadways provide access to launch complexes, support facilities, and industrial areas. Railways transport both cargo and passengers in the region.

There are numerous commercial, private, and military airports within the Deciduous Forest Biome. They vary in size from major international airports such as Hartsfield-Jackson Atlanta International Airport in Georgia that supports 80 million passengers each year to small, rural airstrips that support single engine planes.

The top ports in U.S. foreign trade are deep draft (drafts of at least 12 meters [40 feet]). Twenty-five U.S. ports, located within the Deciduous Forest Coastal Biome, received 73 percent of total vessel calls. (DOT BTS, 2001)

3.2.3.9 Water Resources

Ground water provides about 40 percent of the U.S. public water supply. Where water demand is great, sophisticated reservoir, pipeline, and purification systems are needed to meet demands. Ground water resources along the coast are vulnerable to saltwater intrusion and nutrient contamination. (USGS, 2000)

Water quality in the Deciduous Forest Biome varies depending on pressures from human activity (e.g., industrial effluents and agricultural run-off). Pollution of coastal waters often results from runoff laden with particulates and other pollutants; sewage treatment plants; combined sewer overflows; and storm drains that discharge liquid waste directly into the ocean through pipelines, dumping of materials dredged from the bottoms of rivers and harbors, and waste from fish processing plants, legal and illegal dumping of wastes from ships and ground water from coastal areas.

3.2.4 Chaparral Biome

The Chaparral Biome includes regions corresponding to those shown in Exhibit 3-15, but focuses on a portion of the California Coast and the coastal region of the Mediterranean from the Alps to the Sahara Desert and from the Atlantic Ocean to the Caspian Sea. Representative sites where activities for the proposed BMDS may occur are part of the Western Range, including Vandenberg AFB and the Point Mugu Sea Range.

Exhibit 3-15. Global Distribution of the Chaparral Biome

Source: Modified From National Geographic, 2003b

3.2.4.1 Air Quality

The Chaparral climate consists of hot summer drought and winter rain in the mid-latitudes, north of the subtropical climate zone. The climate in this area is unique with the wet season occurring in winter and annual rainfall of only 38 to 102 centimeters (15 to 40 inches). Cold ocean currents and fog affect temperatures, which limit the growing season. The high-pressure belts of the subtropics drift northwards in the Northern Hemisphere from May to August and they coincide with substantially higher temperatures and little rainfall. During the winter, weather becomes dominated by the rain-bearing low-pressure depressions. While usually mild, such areas can experience cold snaps when exposed to the icy winds of the large continental interiors, where temperatures can drop to -40°C (-40^{o}F) in the extreme continental climates. (Atmosphere, Climate and Environment Programme, 2003)

The primary sources of air pollutants in coastal areas include stationary sources, area sources, mobile sources, and biogenic sources such as forest fires. VOCs react with sunlight in the atmosphere to produce ozone (i.e., smog). In some areas, background levels of air pollutants are relatively high due to air currents depositing pollution from sources outside of the coastal area.

There is a large area along the Pacific coast, particularly in southern California that is in non-attainment for ozone (ranging from severe to extreme). A large area in southern California is in severe non-attainment for PM_{10}. (EPA, 2003f) The EPA has designated the near shore areas of southern California as unclassified/attainment areas. Due to the lack of major emissions sources in the area and the presence of strong northeast winds, the likelihood of pollutants remaining in the ambient air is low.

Heavy industrial activities, high automobile traffic, and energy generation are the main sources of air pollutants along the southern Pacific coast.

The European Union eight-hour air quality standard for ozone (53 nmol/mol) is exceeded throughout the summer in the entire Mediterranean region.

3.2.4.2 Airspace

Airspace in coastal regions of North America contains "North American Coastal Routes," which are numerically coded routes preplanned over existing airways and route systems to and from specific coastal fixes. See Section 3.1.2 for a description of North American Routes.

Portions of the Chaparral Biome are located in international airspace. Therefore, the procedures of the ICAO (outlined in ICAO Document 444, Rules of the Air and Air Traffic Services) are followed.

There are numerous restricted areas in the near shore environment associated with the Western Range. The procedures for scheduling each portion of airspace are performed in accordance with letters of agreement with the controlling FAA facility, Los Angeles Air Route Traffic Control Center (ARTCC).

Numerous airports and airfields exist within the Chaparral Biome. Numerous jet routes that cross the Pacific pass through the U.S. Chaparral Biome, including A331, A332, A450, R463, R465, R584, Corridor V506 and Corridor G10.

3.2.4.3 Biological Resources

The vegetation of the Chaparral is characterized by the presence of hard, tough, evergreen leaves and low, shrubby appearance.

Birds of the Chaparral include the endangered California gnatcatcher (*Polioptila californica*), California thrasher (*Toxostoma redivivum*), western scrub jay (*Aphelocoma californica*), and cactus wren (*Campylorhynchus brunneicapillus*).

The near shore and coastal environment of the Chaparral Biome support numerous threatened or endangered species.

The Chaparral Biomes around the world support 20 percent of all plants, but these areas are all relatively small and many are threatened. Essential Fish Habitat includes those waters and sediment that are necessary to complete the life cycle for fish from spawning to maturity. There are two Essential Fish Habitat zones in this region, coastal pelagic and groundfish.

3.2.4.4 Geology and Soils

The California Coastal Chaparral area consists of narrow ranges with wide plains in between, as well as alluviated lowlands and coastal terraces.

The soils of the Chaparral Biome may be classified into four categories, coastal beach sands, tidal flats, loamy sands, and silty clay. The erosion hazard of these soils depends on slope and vegetation cover.

The California Chaparral Coastal area is noted for its intense seismic activity due to the right lateral motion of the Pacific and North Atlantic Plate boundary.

3.2.4.5 Hazardous Materials and Hazardous Waste

Hazardous materials and hazardous waste attributes of the Chaparral Biome are similar to those discussed in Section 3.2.1.5. Except the moderate climate characteristic of the Chaparral Biome does not require special consideration as is necessary in the extreme temperatures of the Arctic Tundra Biome.

3.2.4.6 Health and Safety

Health and Safety attributes of the Chaparral Biome are similar to those discussed in Section 3.2.1.6.

3.2.4.7 Noise

Vandenberg AFB is a representative example of noise levels for sites where activities for the proposed BMDS may occur in the Chaparral Biome. Ambient noise levels at Vandenberg AFB range from 48 dBA to 67 dBA. (DOT, 2001) Noise sources associated with the proposed BMDS are described in Section 3.2.1.7.

3.2.4.8 Transportation

Transportation attributes of the Chaparral Biome are similar to those discussed in Section 3.2.3.8.

3.2.4.9 Water Resources

Very few perennial streams occur in the Southern California coastal area. There is relative scarcity, on a per capita basis, of freshwater supplies in Mediterranean regions, where agriculture competes for freshwater with growing tourism and industrial use. (UNEP Plan Bleu, 2000)

Water quality attributes of the Chaparral Biome are similar to those described in Section 3.2.3.9.

3.2.5 Grasslands Biome

As shown in Exhibit 3-16, the Grasslands Biome includes the grasslands of North and South America, Eurasia, and Australia. The description in this section is representative of this biome throughout the world. Currently there are no active sites in the Grassland Biome where activities for the BMDS are proposed to occur. However, past military installations within this biome make it reasonable foreseeable that future activity proposed for the BMDS could occur there. There are no reasonably foreseeable coastal sites located in the Grasslands Biome.

Exhibit 3-16. Global Distribution of the Grasslands Biome

Source: Modified From National Geographic, 2003b

3.2.5.1 Air Quality

In the Grasslands Biome, approximately 25 to 76 centimeters (10 to 30 inches) of precipitation falls annually. The temperature varies due to the vast latitudinal span of the grasslands, with annual temperatures ranging from -20ºC to 43°C (-4ºF to 104°F). The average annual temperature across the Grasslands Biome is 24°C (43°F). The low humidity of the Grasslands Biome arises because mountain barriers block warm, moist air from oceans.

Air pollution issues of special concern to the Grasslands Biome are emissions from open burning and fugitive dust.

Due to the low population density of most grassland areas, biogenic (naturally occurring) activities are the predominant sources of air pollution emissions in this biome.

3.2.5.2 Airspace

The U.S. Grassland Biome contains all FAA airspace classifications, as described in Section 3.1.2.

3.2.5.3 Biological Resources

Short grasses, which are predominant throughout the Grasslands Biome, have adapted physiological responses to widespread drought and fire.

Naturally occurring grasslands are becoming harder to find due to human encroachment that can be attributed to increasing population pressures, desire for farmland, and oil exploration, among others. Biological resources of particular concern in the biome are migrating waterfowl and ephemeral prairie potholes.

3.2.5.4 Geology and Soils

The predominant soil type found throughout the Grasslands Biome is characterized by a thick, dark surface horizon resulting from the long-term addition of organic matter derived from plant roots.

There are no significant geological hazards within the Grasslands Biome.

3.2.5.5 Hazardous Materials and Hazardous Waste

Hazardous materials and hazardous waste attributes of the Grasslands Biome are similar to those discussed in Section 3.2.1.5, except that the moderate climate characteristic of

the Grassland Biome does not require special consideration as is necessary in the extreme temperatures of the Arctic Tundra Biome.

3.2.5.6 Health and Safety

Health and Safety attributes of the Grasslands Biome are similar to those discussed in Section 3.2.1.6.

3.2.5.7 Noise

Noise sources associated with the proposed BMDS are similar to those described in Section 3.2.1.7.

3.2.5.8 Transportation

Railroads and motor carriage (i.e., trucking) are the backbone of the freight transportation system in the Grasslands region. The highway system in the prairies consists largely of rural roads, many of which are local roads that are maintained by county and township governments.

3.2.5.9 Water Resources

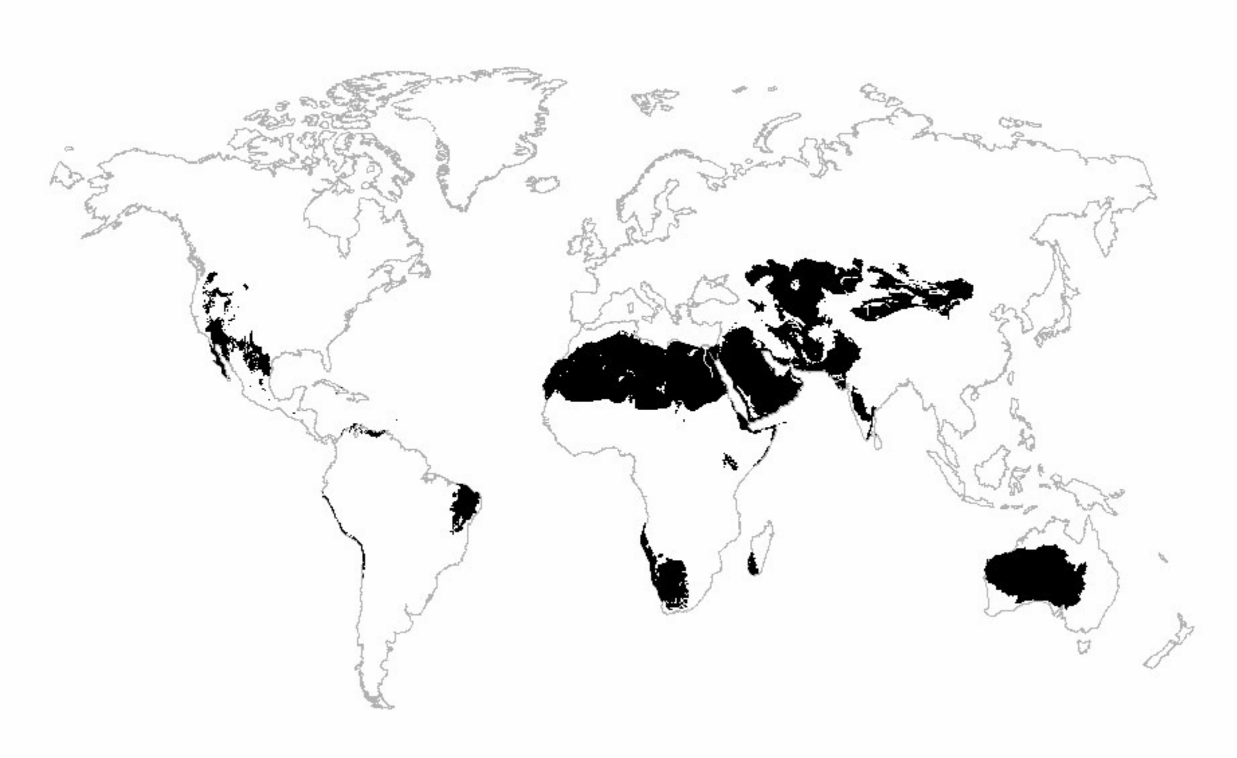
Sources of water in the Grasslands Biome include precipitation, ground water in aquifers, and surface water in rivers, streams, lakes, and wetlands. Due to the heavy dependence on underground water systems for irrigation of the plains' extensive farmland (and to a lesser extent for municipal water systems and industrial development), the depletion of the Grassland Biome's aquifers is of special concern.

The quality of water in the High Plains aquifer generally is suitable for irrigation use, but in many places, the water does not meet EPA drinking water standards with respect to several dissolved constituents: dissolved solids/salinity, fluoride, chloride, and sulfate. (USGS, 2003)

3.2.6 Desert Biome

The Desert Biome includes the desert regions of North America, which include the western arid environment of the southwestern U.S. (See Exhibit 3-17) The description in this section of the U.S. desert is representative of this biome throughout the world. Existing inland sites in the Desert Biome include WSMR, New Mexico; Fort Bliss, Texas; Edwards AFB, California; and the Nevada Test Site, Nevada.

Exhibit 3-17. Global Distribution of the Desert Biome



Source: Modified From National Geographic, 2003b

3.2.6.1 Air Quality

In cold desert regions, temperatures range from 2ºC to 4ºC (36ºF to 39ºF) in the winter and from 21ºC to 26ºC (70ºF to 79ºF) in the summer. Total annual precipitation averages 15 to 26 centimeters (six to ten inches). In contrast, hot desert regions have average monthly temperatures above 18ºC (64ºF), with typical temperatures ranging from 20^{o}C to 25ºC (68^{o}F to 77ºF). Hot desert regions usually have very little precipitation annually and/or concentrated precipitation in short periods, totaling less than 15 centimeters (six inches) per year.

A unique pollutant of concern in desert regions is dust, i.e., PM, which contributes to desertification, the process of creating deserts. Activities that expose and disrupt topsoil, such as grazing and agricultural cultivation common throughout the western U.S., can increase the amount of dust released into the air.

The predominant source of air pollution in the Desert Biome is agriculture, which disturbs the surface layer soil and emits dust into the air.

3.2.6.2 Airspace

The U.S. Desert Biome contains all FAA classifications for airspace, as described in Section 3.1.2.

3.2.6.3 Biological Resources

The Desert Biome encompasses three major vegetation types: semi-desert grassland, plains-mesa sand scrub, and desert scrub.

Desert animals include small nocturnal carnivores, insects, arachnids, reptiles, and birds.

3.2.6.4 Geology and Soils

Nearly 50 percent of desert surfaces are plains where the removal of fine-grained material by wind has exposed loose gravels consisting predominantly of pebbles and occasional cobbles, forming "desert pavement." The remaining surfaces of the Desert Biome are composed of exposed bedrock outcrops, desert soils, and fluvial deposits, including alluvial fans (a cone-shaped deposit of sediments), playas (dry lake beds), desert lakes, and oases. Bedrock outcrops commonly occur as small mountains surrounded by extensive erosional plains.

Desert soils are predominately mineral soils with low organic content. Poorly drained areas may develop saline soils and dry lakebeds may be covered with salt deposits. Geologic hazards within the Desert Biome include earthquakes and landslides.

3.2.6.5 Hazardous Materials and Hazardous Waste

Hazardous materials and hazardous waste attributes of the Desert Biome are similar to those discussed in Section 3.2.1.5.

3.2.6.6 Health and Safety

Health and Safety attributes of the Desert Biome are similar to those discussed in Section 3.2.1.6.

3.2.6.7 Noise

Ambient noise levels for remote desert environments range from 22 to 38 dBA. Ambient noise levels at a representative site where activities for the proposed BMDS may occur within the Desert Biome range from 65 dBA to 85 dBA at Edwards AFB and from 45 dBA to 65 dBA at WSMR. (DOT, 2001) Noise sources associated with the proposed BMDS are described in Section 3.2.1.7.

3.2.6.8 Transportation

Because the population density is so low and dispersed throughout most of the region, transportation infrastructure is concentrated near metropolitan centers.

3.2.6.9 Water Resources

In the Desert Biome, droughts and aquifer supply issues are of particular concern. The leading causes of impairment of rivers and streams include pathogens (bacteria), siltation (sedimentation), and habitat alterations, and the leading sources for these include agriculture, hydraulic modifications, and habitat modifications.

3.2.7 Tropical Biome

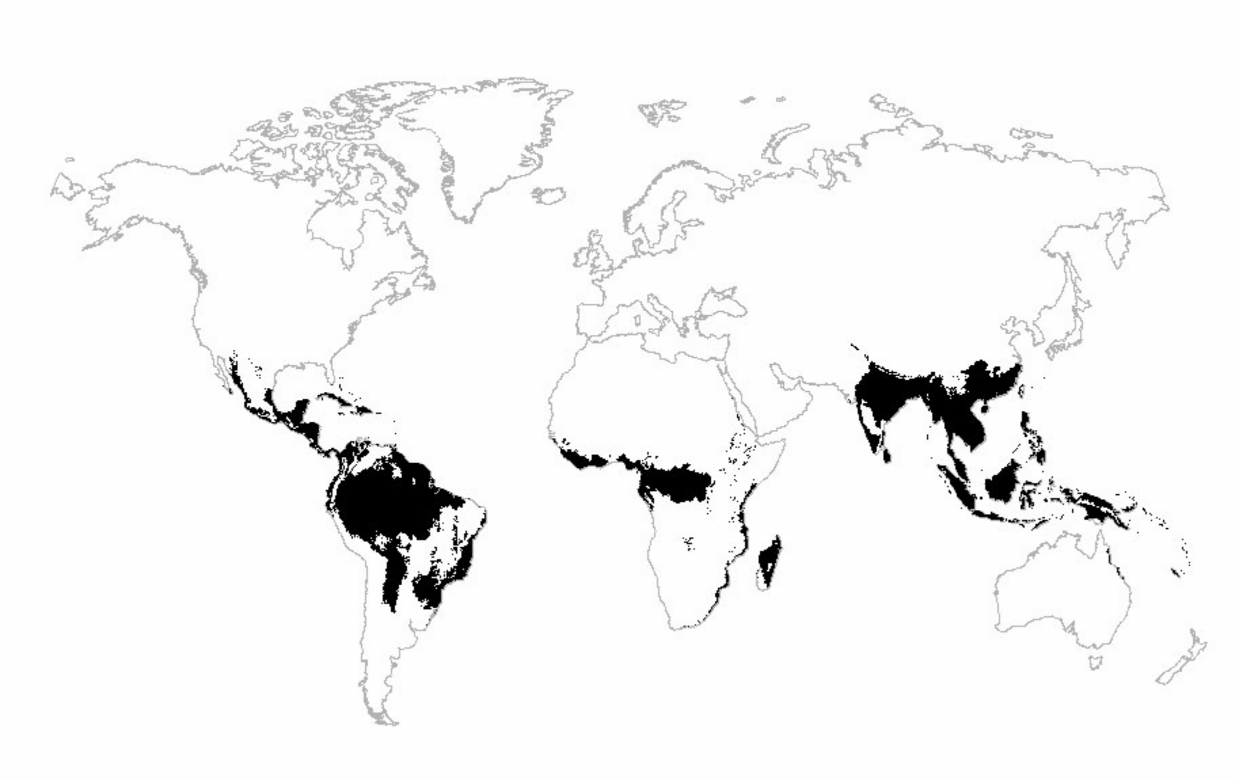
The Tropical Biome[49] encompasses areas within the Pacific and Atlantic Oceans. (See Exhibit 3-18) The coastal zone stretches 1,000 meters (3,281 feet) inland of the coastal shoreline, tidal wetlands, coastal wetlands, and coastal estuaries. (Coastal Planning Coalition of Australia, 2003) Because many of the islands within the Pacific and Atlantic Oceans are relatively small, the entire island may be considered within this Affected Environment section.

The Pacific Tropical Biome would include islands found within the equatorial region. The Pacific contains approximately 25,000 islands, the majority of which are found south of the equator. (Wikipedia, 2003) Current Ranges within this biome where activities of the proposed BMDS may occur include PMRF, U.S. Army Kwajalein Atoll (USAKA), Wake Island, and Midway.

The majority of islands in the Atlantic Tropical Biome are in the Caribbean between the Caribbean Sea and the North Atlantic Ocean.

[49] Exhibit 3-18 shows the global location of the Tropical ecosystem. However, based on reasonably foreseeable locations for activities for the proposed BMDS to occur, the affected environment focuses on the coastal portions of this ecosystem.

Exhibit 3-18. Global Distribution of the Tropical Biome



Source: Modified From National Geographic, 2003b

3.2.7.1 Air Quality

The climate for the Tropical Biome is tropical marine to semi-tropical marine, characterized by relatively high annual rainfall and warm to hot, humid weather throughout the year. Steadily blowing trade winds allow for relatively constant temperatures of 21°C to 27°C (70°F to 81°F) throughout the year. The annual rainfall in the Tropical Biome is approximately 127 to 1,016 centimeters (50 to 400 inches).

Ambient air quality monitoring data are not readily available for islands in the Pacific. In the Caribbean, and Latin America generally, increasing urbanization and rampant forest destruction have led to considerable air quality degradation.

Because of the relatively small numbers and types of air pollution sources, dispersion caused by trade winds, and lack of topographic features at most locations, air quality in the equatorial region is considered good (i.e., well below the maximum pollution levels established for air quality in the U.S.). (U.S. Army Space and Missile Defense Command, 2003)

3.2.7.2 Airspace

The majority of islands in the Pacific Tropical Coastal region are located in international airspace and therefore, the procedures of the ICAO are followed. The Atlantic Pacific Coastal region consists of both U.S. and international airspace.

The procedures for scheduling each portion of airspace are performed in accordance with letters of agreement with the controlling FAA facility.

There are numerous Range-affiliated airport and airfields located within the Pacific Tropical Coastal Affected Environment, including Wake Island, USAKA, PMRF, and Midway. Many of these airfields are engaged in activities similar to those of the proposed activities. Future test events would act in accordance with existing activities at the airfields. The majority of local airports within the Atlantic Tropical Coastal region handle smaller, private aircraft, which are uncontrolled.

High-altitude overseas jet routes cross the Pacific Tropical Coastal region via nine Control Area Extension corridors off the California coast.

3.2.7.3 Biological Resources

Vegetation and wildlife in the Tropical Biome is among the most biologically diverse in the world.

There are numerous environmentally sensitive habitats within the Tropical Biome, including barrier reefs, whale sanctuaries, and fisheries.

3.2.7.4 Geology and Soils

Islands within the Pacific Tropical Biome range from atolls with small, low inlets and extensive lagoons, to raised limestone islands, to volcanic high islands with substantial topographic and internal climatic diversity. Coral reefs have developed upon the eroded platforms around some of the islands.

Islands within the Atlantic Tropical Biome are composed of two distinctive chains of islands, the Lesser and Greater Antilles. The islands are characterized by a range of geological formations, from volcanic and sedimentary strata to coral limestone and alluvium.

The soils on smaller atolls in the Pacific Ocean have low fertility due to alkalinity. The soils are permeable, and infiltration is rapid. Wind erosion is severe when vegetation has been removed.

The islands within the Atlantic Tropical Biome include a wide range of soils, which may be derived from limestone, serpentine, dolomite, basalt, granite, diorite, gabbro, sandstone, or slate.

Volcanic islands within the Pacific Ocean have been built of successive lava flows. Volcano eruptions occur relatively frequently on the islands. (NOAA, 2003b)

In the Atlantic region, many earthquakes and tsunamis have occurred in the northeastern Caribbean, where the movements of the Earth's surface plates are rapid and complicated. (USGS, 2001) Volcanoes erupt on the eastern and western sides of the Caribbean plate.

3.2.7.5 Hazardous Materials and Hazardous Waste

Hazardous materials and hazardous waste attributes of the Tropical Biome are similar to those discussed in Section 3.2.1.5. However, the moderate climate characteristic of the Desert Biome does not require consideration as is necessary in the extreme temperature of the Arctic Tundra Biome.

3.2.7.6 Health and Safety

Health and Safety attributes of the Tropical Biome are similar to those discussed in Section 3.2.1.6.

3.2.7.7 Noise

Natural background sound levels in the Tropical Biome are relatively high due to wind and surf. Sources of noise in the Tropical Biome are similar to principle sources of noise associated with sites where activities for the proposed BMDS may occur, as described in the Section 3.2.1.7.

3.2.7.8 Transportation

The smaller islands may require marine transport vessels to transport passengers and supplies between islands. The isolated locations of the equatorial environments make transportation vital to many of the locations. Ground transportation facilities consist of roadways and pathways used by motor vehicles, bicycles, and pedestrians. Ships and smaller craft carry ocean cargo and fuel to the Equatorial Islands and deliver workers and cargo, including fuel, between islands.

3.2.7.9 Water Resources

Seasonal rainfall is the primary source of freshwater for most small islands. Catchments are used to capture rainfall for potable use. Raw water is stored in aboveground storage

tanks. Coastal areas of the Caribbean near major watersheds often contain large lagoons of fresh or brackish water.

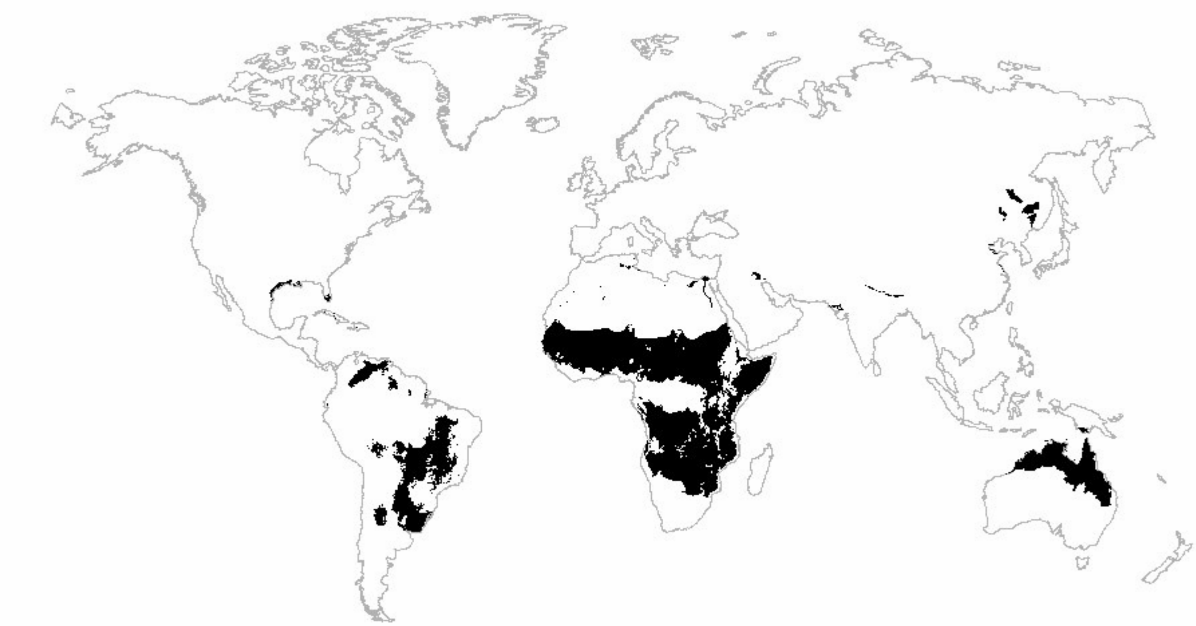
Of the land-based sources of pollution, eutrophication, or nutrient enrichment, from human sewage disposal is a growing problem in the Caribbean, particularly in the vicinity of large coastal cities and harbors.

Pacific Island water quality is generally of very high, with high dissolved oxygen and pH at levels typical of mid-oceanic conditions.

3.2.8 Savanna Biome

The Savanna Biome includes the transitional zone between the tropical forest and the semi-desert scrub vegetation types and typically occupies latitudes between 5º and 20º North and South of the equator (see Exhibit 3-19). Savannas cover extensive areas in the tropics and subtropics of Central and South America, Central and South Africa, and northern Australia in both inland and coastal environments. Currently there are not sites in the Savanna Biome where activities are proposed for the BMDS; however, it is reasonably foreseeable that future activity for the BMDS could occur here. The description in this section is representative of this biome throughout the world.

Exhibit 3-19. Global Distribution of the Savanna Biome



Source: Modified From National Geographic, 2003b

3.2.8.1 Air Quality

Towards the equator, annual rainfall is typically higher relative to the more poleward edges of the Savanna belt, and total annual precipitation may be as high as 250 centimeters (98 inches). On the Savanna edges nearest the tropics (towards the poles), annual rainfall totals may be as little as 50 centimeters (20 inches). In Australian savanna environments, coastal areas receive twice as much rainfall as inland savannas.

Annual temperatures in the Savanna Biome are relatively constant, averaging roughly 24ºC to 27ºC (75ºF to 80ºF).

The Savanna Biome faces similar air quality concerns as those found in the Grassland Biome, namely emissions from open burning, natural drought-driven fires, and other fugitive dust.

Fire is a predominant emission source, while anthropogenic activities, such as agriculture and mining also contribute.

3.2.8.2 Airspace

The Savanna Biome is located in international airspace; and therefore, the procedures of the ICAO are followed.

3.2.8.3 Biological Resources

Savannas are characterized by a continuous cover of perennial grasses, often one to two meters (three to six feet) tall at maturity. They also may have an open canopy of drought- or fire-resistant trees or an open shrub layer.

National parks and reserves have been established to preserve and protect threatened vegetative and wildlife species in the Savanna Biome. However, the parks are vastly under funded and often poorly managed.

3.2.8.4 Geology and Soils

Savannas typically have porous (often sandy) soil, with only a thin covering of nutrient-rich humus and an overall low concentration of nutrients.

Savannas are similar to grasslands in geologic and topographic features, predominantly characterized by flat terrain and may be marked with escarpments and other plateau-like features of sandstone or limestone composition. There are no significant geological hazards throughout the Savanna Biome.

3.2.8.5 Hazardous Materials and Hazardous Waste

There are no existing facilities proposed for use in the BMDS in the Savanna Biome. However, future sites would use hazardous materials similar to those in use at existing sites discussed in this chapter and would produce similar hazardous wastes.

Any future facilities that may be used as part of the proposed BMDS would adhere to all applicable legal requirements for hazardous materials and hazardous waste management as described in Section 3.1.7.

3.2.8.6 Health and Safety

Health and safety attributes of the Savanna Biome are similar to those discussed in Section 3.2.1.6.

3.2.8.7 Noise

Noise sources associated with the proposed BMDS in the Savanna Biome are similar to those described in Section 3.2.1.7.

3.2.8.8 Transportation

Transportation in the Savanna Biome is typically limited due to the frequently remote and rural nature of savannas. Highways, if present, are typically unpaved and may not be regularly maintained due to the low volume of traffic carried and remote locations. Railways are not a dominant form of transportation in the Savanna Biome.

Airports with paved runaways are scarce in the Savanna Biome.

Navigable waterways are present in some wetter savannas and may be used to transport goods to ports along coastal savannas.

3.2.8.9 Water Resources

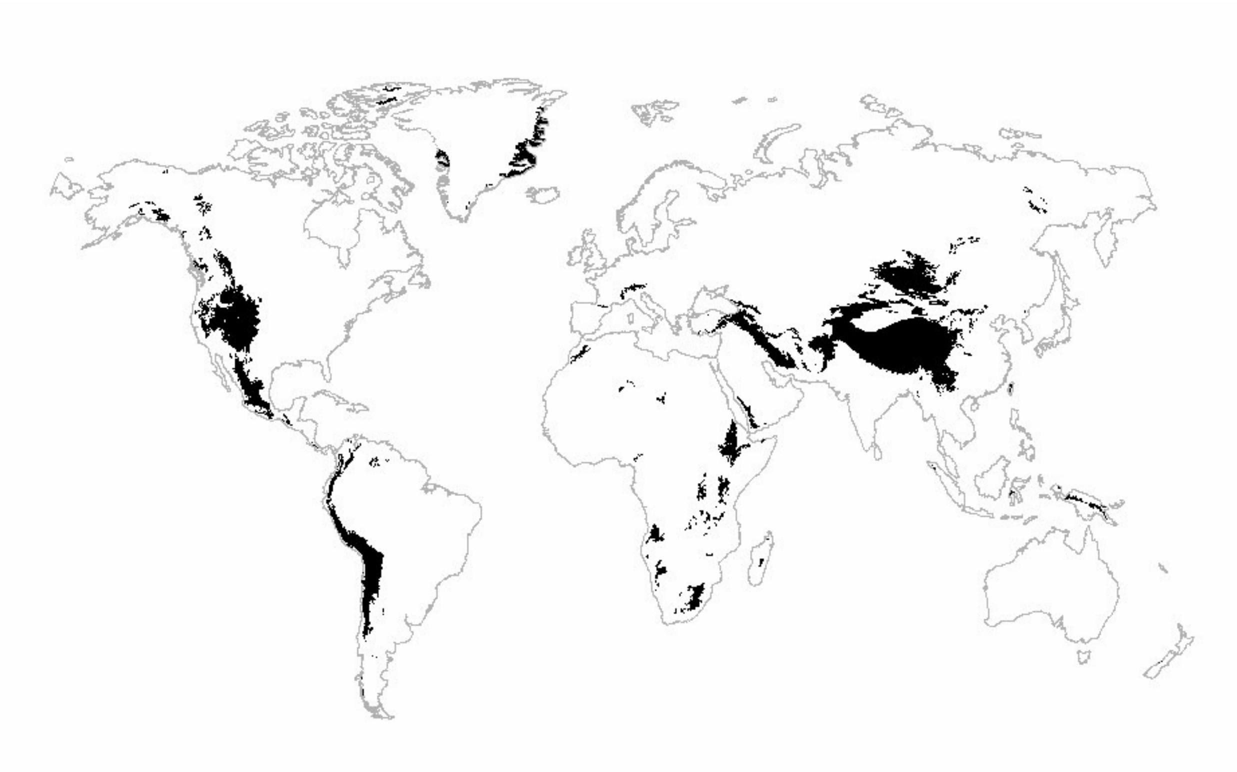
Savanna water resources are highly vulnerable to the effects of weed invasion, feral animals, overgrazing, and fire. Water resources are further strained by heavy water use in riparian areas for agriculture and tourism. (Douglas and Lukacs, 2004)

Water quality problems most commonly are caused by livestock and feral animals during the dry season.

3.2.9 Mountain Biome

As shown in Exhibit 3-20, the Mountain Biome includes the mountainous regions of North America and Europe, which include the Rocky Mountains in the western U.S. and the Alps in central Europe. The description in this section is representative of this biome throughout the world. Mountain Biomes are found at high altitudes and lie just below and above the snow line of a mountain. Existing inland sites in the Mountain Biome include Buckley AFB, Cheyenne Mountain AFB and Fort Carson Military Reserve, Colorado; and F.E. Warren AFB, Wyoming.

Exhibit 3-20. Global Distribution of the Mountain Biome



Source: Modified From National Geographic, 2003b

3.2.9.1 Air Quality

Given its high altitude, the Mountain Biome is characteristically cold with heavy snowfall and frequently bitter winds. Temperatures remain below freezing for at least seven months of the year, and in the summer, average temperatures range from 10°C to 15°C (50°F to 59°F). The average precipitation across mountain environments is 30 centimeters (12 inches) a year.

Mountain Biomes exhibit particular sensitivity to air pollution via deposition of both wet and dry pollutants, principally in snowpacks, which can in turn result in reduced surface water quality. Regional air pollutants of concern to mountainous areas include visibility-reducing PM, deposition of nitrogen and sulfur compounds, ozone, greenhouse gases that contribute to localized warming, and air toxics such as mercury and persistent organic pollutants.

Typical sources of air pollutants in the Mountain Biome include population centers, energy development and power plants, and agricultural activities.

3.2.9.2 Airspace

The U.S. Mountain Biome contains all FAA classifications for airspace, as described in Section 3.1.2.

3.2.9.3 Biological Resources

The high elevations of the mountain environments have harsh climatic conditions that support about 200 species of mountain plants.

Mountain animals have to tolerate cold temperatures and intense ultraviolet radiation. Because of the year-round cold, only warm-blooded animals can survive in the Mountain Biome, although insects also exist.

Some mammals within the Mountain Biome are considered sensitive species and may warrant special conservation measures, including critical habitat designation. Because food chains may be shorter in this biome than in more temperate biomes, food chains are more sensitive to environmental changes.

3.2.9.4 Geology and Soils

Much of the Mountain Biome appears as barren rock or a cover of thin soils. Soils in the biome are relatively fragile and are subject to erosion when disturbed.

The Mountain Biome is a complex network of mountain ranges characterized by extreme physiographic variability. Wide differences in elevation, slope steepness, and exposure exist locally and between major mountain masses.

Mountain Biomes are subject to numerous geological hazards, including earthquakes, landslides, and volcanoes.

3.2.9.5 Hazardous Materials and Hazardous Waste

Hazardous materials and hazardous waste attributes of the Mountain Biome are similar to those discussed in Section 3.2.1.5.

3.2.9.6 Health and Safety

Health and Safety attributes of the Mountain Biome are similar to those discussed in Section 3.2.1.6.

3.2.9.7 Noise

Sources of noise in the Mountain Biome are similar to principle sources of noise associated with sites where activities for the proposed BMDS may occur, as described in Section 3.2.1.7.

3.2.9.8 Transportation

The Mountain Biome sustains widespread infrastructure, including traffic circulation systems such as highways and byways, unpaved roads, non-maintained roads, trails, railroad lines, municipal, private, and military airports and any other system involved in mass transportation.

Due to the extreme cold and heavy snowfall characteristic of the Mountain Biome, airports within this region require the ability to provide landing access under zero visibility conditions such as blizzards and de-icing capability.

3.2.9.9 Water Resources

Surface water resources in the Mountain Biome include glacial lakes, streams, and rivers fed by rainfall and melting snow and those that originate from ground water sources. Mountain lakes are particularly sensitive to the effects of acidification because they have soft water, which does not neutralize acid readily.

In the Mountain Biome, elevated levels of contaminants accumulate in snowpacks, negatively impacting local flora and fauna. Upon melting, the concentrated pollutants are dispersed throughout the area watershed, deteriorating the quality of downstream surface and ground water systems. (USGS, 2003)

3.2.10 Broad Ocean Area

For purposes of this PEIS, the BOA encompasses the Pacific Ocean, the Atlantic Ocean, and the Indian Ocean.

Proposed activities in the BOA would take place at a distance of several hundred kilometers from any land mass. The BOA is subject to EO 12114, *Environmental Effects Abroad of Major Federal Actions,* which requires consideration of Federal actions abroad with the potential for impacts to the environment.

The Pacific Ocean is comprised of approximately 156 million square kilometers (60 million square miles) and includes the Bali Sea, Bering Sea, Bering Strait, Coral Sea, East China Sea, Flores Sea, Gulf of Alaska, Gulf of Tonkin, Java Sea, Philippine Sea, Savu Sea, Sea of Japan, Sea of Okhotsk, South China Sea, Tasman Sea, Timor Sea, and other tributary water bodies. Its maximum length is 14,500 kilometers (9,000 miles) and its greatest width is 17,700 kilometers (11,000 miles), which lies between the Isthmus of Panama and the Malay Peninsula. (Encyclopedia.com, 2003)

The Atlantic Ocean is comprised of approximately 76.8 million square kilometers (29.6 million square miles) and includes the Baltic Sea, Black Sea, Caribbean Sea, Davis Strait, Denmark Strait, part of the Drake Passage, Gulf of Mexico, Mediterranean Sea, North Sea, Norwegian Sea, almost all of the Scotia Sea, and other tributary water bodies. The Atlantic Ocean extends from the North Pole southward for about 16,100 kilometers (10,000 miles) to the Antarctic continent, and covers 106 million square kilometers (41 million square miles). The width of the Atlantic varies from approximately 2,850 kilometers (1,770 miles) between Brazil and Liberia to 4,830 kilometers (3,000 miles) between Norfolk, VA, and Gibraltar. The average depth is about 3,660 meters (12,000 feet) and the greatest depth is 8,650 meters (28,400 feet) in the Puerto Rico Trench. (Oceans of the World, 2003)

The Indian Ocean is comprised of about 68 million square kilometers (26 million square miles) and includes the Andaman Sea, Arabian Sea, Bay of Bengal, Great Australian Bight, Gulf of Aden, Gulf of Oman, Mozambique Channel, Persian Gulf, Red Sea, Strait of Malacca, Timor Sea, and other tributary water bodies. (CIA, 2003) It is triangular and bordered by Africa, Asia, Australia, and the Southern Ocean. Its maximum width is about 10,000 kilometers (6,200 miles) between the southernmost portions of Africa and Australia, and its average depth is approximately 4,000 meters (13,120 feet). The greatest depth occurs in the Java Trench at approximately 7,300 meters (24,000 feet) below sea level. (Oceans of the World, 2003)

3.2.10.1 Air Quality

No sources of ambient air quality monitoring data are known to exist for the BOA. There are no known existing emission sources in the Pacific Ocean. Air quality over the Pacific Ocean is expected to be good because there are no major sources of air pollution, and the nearly constant trade winds in the area serve to disperse any pollutants from transient sources, such as passing seagoing vessels or low-flying aircraft.

In the Atlantic Ocean, there is potential for large, thick plumes of aerosols blowing eastward over the North Atlantic. The aerosol plume is the regional haze produced by the industrial northeastern U.S. and typically occurs during the summer months. The haze is composed of sulfates and organics that originate from power plants and automotive sources. (NASA, 2003a) Ozone and other pollutants found in the Atlantic Ocean are primarily the result of anthropogenic sources.

A monitoring station in the Maldives Islands records air quality in the Indian Ocean. (Environmental News Network, 1999) The aerosol cloud covering much of the northern Indian Ocean originates primarily (at least 85 percent) from anthropogenic sources (Max Planck Society, 2001), namely agricultural and other biomass burning, the use of biofuels, and fossil fuel combustion in South and Southeast Asia. (Lelieveld et al., 2001) Model calculations indicate that, in contrast to European and North American pollution, anthropogenic emissions from South and East Asia reduce the concentration of hydroxyl (OH) radicals. Because OH is a powerful oxidant and acts as an atmospheric cleansing agent, the Asian pollution decreases the oxidizing power of the atmosphere, contributing to greater pollution problems over the Indian Ocean. (Max Planck Society, 2001)

Air quality over the Indian Ocean is seasonally poor due to anthropogenic emissions from growing South and Southeast Asian countries, particularly India. During the dry monsoon season (northern hemisphere winter), air pollutants in South and Southeast Asia are transported long distances to the Indian Ocean by persistent northeasterly monsoon winds. A dense, brown haze covers an area greater than 10 million square kilometers (3,900 million square miles) over most of the northern Indian Ocean (Max Planck Society, 2001), including the Arabian Sea, much of the Bay of Bengal, and part of the equatorial Indian Ocean to about five degrees south of the equator. (Environmental News Network, 1999) The haze extends from the ocean surface up to three kilometers (two miles). Comprised primarily of soot, sulfates, nitrates, organic particles, fly ash, and mineral dust, the airborne particles can reduce visibility over the BOA to less that 10 kilometers (6.2 miles) and reduce the solar heating of the ocean by about 15 percent. The haze also contains relatively high concentration of gases, including CO, SO_2, and other organic compounds. (Environmental News Network, 1999)

3.2.10.2 Airspace

Because the airspace in the BOA is beyond the territorial limit and is in international airspace, the procedures of the ICAO, outlined in ICAO Document 444, *Rules of the Air and Air Traffic Services* are followed. The FAA acts as the U.S. agent for aeronautical information to the ICAO.

Domestic Warning Areas are established in international airspace to contain activity that may be hazardous and to alert pilots of nonparticipating aircraft to the potential danger.

There are no airports or airfields located in the BOA.

High-altitude overseas jet routes cross the Pacific BOA via nine Control Area Extension corridors off the California coast.

3.2.10.3 Biological Resources

Marine biology of the open ocean consists of the animal and plant life that lives in and just above the surface waters of the sea and its fringes.

3.2.10.4 Geology and Soils

The Pacific Ocean floor of the central Pacific basin is relatively uniform, with a mean depth of about 4,270 meters (14,000 feet). (Oceans of the World, 2003) The Pacific Ocean is surrounded by a zone of violent volcanic and earthquake activity sometimes referred to as the "Pacific Ring of Fire." Icebergs are common in the Davis Strait, Denmark Strait, and the northwestern Atlantic Ocean from February to August and have been spotted as far south as Bermuda and the Madeira Islands. (Oceans of the World, 2003)

The principal feature of the bottom topography of the Atlantic BOA is a great submarine mountain range called the Mid-Atlantic Ridge. It extends from Iceland in the north to approximately 58 degrees south latitude, reaching a maximum width of about 1,600 kilometers (1,000 miles).

The Mid-Ocean Ridge dominates the terrain of the Indian Ocean floor. The Indian Ocean is subdivided by the Southeast Indian Ocean Ridge, Southwest Indian Ocean Ridge, and the Ninetyeast Ridge. (CIA, 2003)

Ocean sediments are composed of terrestrial, pelagic (open sea), and authigenic (grows in place with a rock) material. Terrestrial deposits consist of sand, mud, and rock particles formed by erosion, weathering, and volcanic activity on land and then washed to sea. (Wikipedia, 2003) Occasional icebergs occur in the southern reaches of the Indian Ocean. (CIA, 2003)

3.2.10.5 Hazardous Materials and Hazardous Waste

For test events using sea-based platforms, hazardous materials would be handled and used in accordance with all applicable state and Federal regulations as well as range-specific and U.S. Navy standard operating procedures.

The Clean Water Act prohibits the discharge of hazardous substances into or upon U.S. waters out to 370 kilometers (200 nautical miles). Also shipboard waste handling

procedures for commercial and U.S. Navy vessels govern the discharge of hazardous wastes as well as non-hazardous waste streams. These categories include "blackwater" (sewage); "greywater" (leftover cleaning water); oily wastes; garbage (plastics, non-plastics, and food-contaminated waste); hazardous wastes; and medical wastes. (U.S. Department of the Navy, 2002b)

The Uniform National Discharge Standards provisions of the Clean Water Act provide for the evaluation of the 39 discharges from U.S. Navy Vessels. Section 312(n)(2)(B) of the Clean Water Act identifies seven factors for consideration when determining if a discharge requires a marine pollution control device: the nature of the discharge; the environmental effects of the discharge; the effect that installing or using the marine pollution control device has on operations or the operational capability of the vessel; applicable Federal and state regulations; applicable international standards; and the economic costs of installing and using the marine pollution control device.

Under the regulations implementing the Act to Prevent Pollution from Ships, as amended, and the Marine Plastics Pollution Research and Control Act, the discharge of plastics, including synthetic ropes, fishing nets, plastic bags, and biodegradable plastics, into the water is prohibited. A slurry of sea water, paper, cardboard, or food waste that is capable of passing through a screen with opening no larger than 12 millimeters (0.4 inch) in diameter may not be discharged within 5.6 kilometers (three nautical miles) of land. Discharge of floating dunnage, lining, and packing materials is prohibited in navigable waters and in areas offshore less than 46.3 kilometers (25 nautical miles) from the nearest land.

Test event sponsors would be responsible for tracking hazardous wastes; for proper hazardous waste identification, storage, transportation, and disposal; and for implementing strategies to reduce the volume and toxicity of the hazardous waste generated. For test events using a sea-based platform, hazardous materials and hazardous waste would be managed in accordance with all applicable state and Federal regulations as well as Range-specific and U.S. Navy standard operating procedures.

The transport, receipt, storage, and handling of hazardous materials would comply with Army TM 38-410, Navy NAVSUP PUB 505, Air Force AFR 69-9, Marine Corps MCO 4450-12 or Defense Logistics Agency DLAM 4145.11, Storage and Handling and Implementing Regulations Governing Storage and Handling of Hazardous Materials.

3.2.10.6 Health and Safety

The region of influence for health and safety in the BOA would be limited to work crews located on sea-based platforms. The WorldWide Navigational Warning Service is a worldwide radio and satellite broadcast system for the dissemination of Maritime Safety Information to U.S. Navy and merchant ships. The WorldWide Navigational Warning

Service provides timely and accurate long range and coastal warning messages promoting the safety of life and property at sea and Special Warnings that inform mariners of potential political or military hazards that may affect safety of U.S. shipping.

3.2.10.7 Noise

Studies of ambient noise of the ocean have found that the sea surface is the predominant source of noise above the water, and that the source is associated with the breaking of waves. (Knudsen, et al., 1948, as referenced in FAA, 2001a) The primary human-made noise source within the BOA is associated with ship and vessel traffic, including transiting commercial tankers and container ships, commercial fishing boats, and military surface vessels and aircraft. Noise sources above the water would also include launch or other activities from sea-based platforms.

Noise also occurs under the ocean surface. The dominant sources of ambient underwater noise and their corresponding frequency ranges are seismic activity, turbulent-pressure fluctuations, and second order pressure effects due to surface gravity waves (1to 100 Hz); ship traffic and industrial activity (10 Hz to 10 kHz); biologics (10 Hz to 100 kHz); sea ice activity (10 Hz to 10kHz); breaking waves, bubbles, and spray (100 Hz to 20 kHz); precipitation (100 Hz to 30 kHz); and thermal effects (30 to 100 kHz). Noise from sources above the water may be magnified underwater. For example, a tug and barge produces sound that measures 171 dB in water and 110 dB in air. (Gisiner, 1998)

3.2.10.8 Transportation

The Transportation in the BOA consists predominantly of marine shipping. Marine shipping refers to the conveyance of freight, commodities, and passengers via mercantile vessels.

3.2.10.9 Water Resources

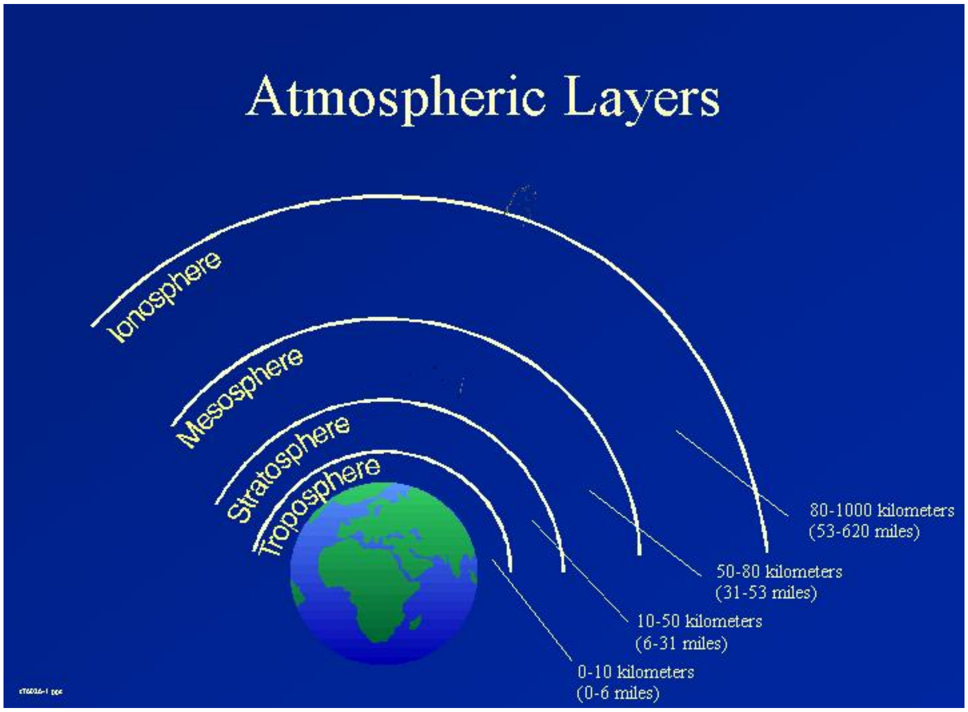
The two main factors that define ocean water are the temperature and the salinity of the water. (UCAR, 2001b) Water quality in the open ocean is considered excellent, with high water clarity, low concentrations of suspended matter, dissolved oxygen concentrations at or near saturation, and low concentrations of contaminants such as trace metals and hydrocarbons

3.2.11 Atmosphere

The Atmosphere Environment refers to the Atmosphere that envelops all areas of the Earth and consists of the four principal layers of the Earth’s atmosphere: troposphere,

stratosphere, mesosphere, and ionosphere or thermosphere.[50] These layers are characterized by altitude, temperature, structure, density, composition, and degree of ionization – the positive or negative electric charge associated with each layer. Altitude ranges for atmospheric layers are described in Exhibit 3-21.

Exhibit 3-21. Altitude Range for Atmospheric Layers



Source: ICF Kaiser for Beal Aerospace, 1998

3.2.11.1 Air Quality

During the past 150 years, combustion of fossil fuels has resulted in increasing concentrations of atmospheric gases that are believed to influence global climate. The temperature of the Earth's atmosphere is determined by three factors: the sunlight it receives, the sunlight it reflects, and the infrared radiation absorbed by the atmosphere. The principal absorbers include CO_2, water vapor, nitrous oxide, chlorofluorocarbons (CFCs), and methane.

3.2.11.2 Airspace

Exhibit 3-22 illustrates the relationship between airspace classifications and atmospheric layers.

---

[50] Most resource areas do not apply to the Atmosphere. Therefore, the Affected Environment discussion includes only Air Quality, Airspace, and Biological Resources, and consideration of Orbital Debris.

Exhibit 3-22. Relationship Between Airspace Classifications and Atmospheric Layers

Type of Airspace	Altitude (from MSL)	Atmospheric Layer(s)
Controlled	> 5.5 kilometers (3.4 miles)	Troposphere, Stratosphere
Uncontrolled	< 4.4 kilometers (2.7 miles)	Troposphere

3.2.11.3 Biological Resources

While the atmosphere generally is not considered to contain biological resources, atmospheric conditions have a direct impact on climate, which affects the location and health of biological resources.

3.2.11.4 Orbital Debris

Although there is no absolute definition of space, it can generally be defined at an altitude approximately 100 kilometers (62 miles) from the Earth's surface, where the aerodynamic forces of the thinning atmosphere become so small that the various control surfaces of an aircraft (e.g., rudder, aileron, and elevator) cease to function effectively. Space is not generally considered to be part of the human environment, as defined by NEPA and therefore, the discussion of impacts to space for this PEIS will be limited to the impacts from orbital debris. Orbital debris is man-made material introduced by spacecraft. The debris can be as large as spent rocket motors and as small as dust particles released during motor firings. Orbital debris that remains on orbit could create hazards to orbiting spacecraft, to astronauts or cosmonauts engaged in extra-vehicular space activities and it could have impacts upon reentry if the debris reaches the Earth's surface in large pieces or contains hazardous components. The effects of orbital debris on other spacecraft depend on the altitude, orbit, velocity, angle of impact, and mass of the debris. Eventually this orbiting debris loses energy and drops into consecutively lower orbits until it reenters Earth's atmosphere. Orbital debris has no impact on the human environment unless and until the debris enters the Earth's atmosphere. De-orbiting debris (i.e., debris reentering the atmosphere from orbit) is a potential concern as a course of deposition of small particles into the stratosphere, and a possible contributor to stratospheric ozone depletion.

4 ENVIRONMENTAL CONSEQUENCES

Introduction

This Section of the PEIS describes the potential environmental consequences of implementing the proposed action via Alternatives 1 and 2 in various worldwide biomes, the BOA or the atmosphere. This Section also identifies potential cumulative impacts associated with those alternatives. It is intended to address the impacts in the context of worldwide biomes based on similar ecological characteristics rather than political boundaries. Only BMDS Programs and activities that are considered reasonably foreseeable are analyzed in this PEIS. Programs that are still conceptual in nature are not analyzed in this document.

This PEIS provides a comprehensive, global analytical framework that can support subsequent analysis of specific actions at specific locations, as appropriate. A description of the analytical framework follows in the next section. The manner and extent to which future actions tier from the PEIS is left to the discretion of the preparer. The framework established in this document is intended to serve as a guide for preparing future site-specific documents and does not dictate their preparation.

This PEIS also contemplates BMDS activities outside the jurisdictional limits of the U.S. and therefore beyond the scope of NEPA and other Federal U.S. laws. The DoD addresses these issues primarily in DoD Directive 6050.7 and DoD Instruction 4715.5. See Appendix G for a description of the framework to be used for this process.

Cumulative impacts of Alternatives 1 and 2 are also considered. The CEQ NEPA regulations define cumulative impacts as the impacts on the environment that result from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions (40 CFR § 1508.7).

Cumulative impacts can result from individually minor, but collectively significant, actions taking place over a period of time. For this PEIS, potential cumulative impacts are addressed for activities that would occur on a scale similar to the proposed BMDS. Thus, activities were considered that are national or international in scope. Future activities were identified based on review of worldwide rocket launches and commercial and government space programs.

As a result of the public comment process, additional areas of analysis – orbital debris, perchlorate, and radar impacts on wildlife – have been addressed in more technical detail in Appendices L, M, and N, respectively.

Analysis Process

Because of the extensive nature of this project, this PEIS analyzes the BMDS as described in the following four steps.

- **Step 1 – Identify and Characterize Activities** for each BMDS component.
- **Step 2 – Identify Activities with No Potential for Impact** and dismiss those for which prior NEPA analysis determined insignificant impacts or those that are categorically excluded.
- **Step 3 – Identify Similar Activities across Life Cycle Phases** for activities that are determined to have similar environmental impacts.
- **Step 4 – Conduct Environmental Analyses** for the remaining life cycle activities for each component.

Step 1 – Identify and Characterize Activities

The BMDS is organized by component (i.e., weapons; sensors; C2BMC; and support assets). Each component has life cycle activities associated with developing, testing, deploying, and decommissioning those components within the BMDS. These activities produce environmental impacts which are examined in this PEIS.

To consider impacts of the BMDS, the emissions/stressors from the component life cycle activities were identified and characterized. Exhibit 1-3 displays the typical activities within each life cycle phase for each component.

Step 2 – Identify Activities with No Potential for Impact

Actions for which previous NEPA analyses indicated no significant impacts[51] or actions that are normally categorically excluded[52] were not analyzed in detail in this PEIS. Exhibit 4-1 identifies activities for which categorical exclusions are generally available. These activities are not further analyzed in this PEIS.

---

[51]After scrutinizing NEPA documents for programs and elements (see Appendix D), it was determined that there was no significant impact from several BMDS life cycle activities because these activities have been previously analyzed and were shown to have no impact.

[52] In accordance with CEQ regulations for implementing NEPA (40 CFR 1507.3(b)), the DoD and military services have developed regulations that provide for the establishment of categorical exclusions (40 CFR 1507.3(b)) for those actions, which do not individually or cumulatively have a significant impact on the human environment. Where appropriate, DoD and military services have established categorical exclusions for such activities. For example, infrequent, temporary (less than 30 days) increases in air operations up to 50 percent of the typical installation aircraft operation rate are categorically excluded. See Appendix G, Exhibit G-1 for citations of DoD NEPA implementing regulations categorical exclusions.

Exhibit 4-1. Life Cycle Activities Determined to Have No Significant Environmental Impact

Life Cycle Phase	Activities
Development	Planning/Budgeting
	Research and Development
	Systems Engineering
	Tabletop Exercises
Deployment	Training

Some activities such as transportation of components, maintenance and sustainment, and manufacturing were determined to need no further analysis in this PEIS either because they have been categorically excluded or addressed in previous NEPA analyses and found to have no significant impacts. The rationale for these conclusions is presented in Sections 4.1.1.8, 4.1.1.9, and 4.1.1.10, respectively, of this PEIS.

Step 3 – Identify Similar Activities across Life Cycle Phases

The remaining activities with the potential for environmental impacts were then examined to determine which had similar environmental impacts. For example, impacts associated with site preparation and construction in the development phase would be similar to or the same as impacts from site preparation and construction activities in the testing and deployment phases of the life cycle. Accordingly many activities were addressed together to eliminate redundancy.

Many activities in the various life cycle phases have been combined in the analysis of Support Assets. This was done because activities associated with support assets whether infrastructure, equipment or test assets (including countermeasures and simulants), were considered similar in terms of impacts created. Some activities require the use of operating platforms, such as aircraft for air-based components or ships for sea-based components; these specific platforms are considered support assets. Impacts from the use of operating platforms are discussed as part of Support Assets. Details of the life cycle phase analysis are provided below (Life Cycle Phase Activities). Exhibits 4-2 through 4-5 illustrate by life cycle phase, the activities that are analyzed in this PEIS and the corresponding section in which the analysis can be found.

Step 4 – Conduct Environmental Analyses

The significance of an impact that an activity has on the environment is a function of the nature of the receiving environment. For example, a booster launch has different emissions than those from activating a chemical laser. Whether those emissions create

impacts and the degree of significance of these impacts depends upon the environment in which they are released.

In this analysis, the PEIS considers the emissions/stressors from each component's activity in the context of each resource area (e.g., air, water, etc.). Impacts were distinguished based on the different operating environments (land, sea and air for Alternative 1 and land, sea, air and space for Alternative 2) in which the activity would occur. These impacts were further distinguished based on the worldwide biomes in which the activity would occur.

As a result, the PEIS is organized by component; the analysis examines each resource area and distinguishes between operating environments in the context of a particular biome. The analysis also describes where the impacts differ based on the operating environment or biome.

Life Cycle Phase Activities

Development Phase Activities

Exhibit 4-2 shows the activities in the development life cycle phase that were considered to produce environmental impacts and where in the analysis each activity is addressed. Planning and budgeting; research and development; systems engineering; and tabletop exercises are activities for which categorical exclusions are generally available; therefore these activities are not further analyzed in this PEIS. Manufacturing of prototypes and maintenance and sustainment are routine activities that have been considered in previous NEPA analyses and determined to have no significant impact or are categorically excluded and are not considered further in this PEIS. Site preparation and construction and testing are part of other life cycle phases for the proposed BMDS. To eliminate redundancy these activities are addressed together. Testing of component prototypes has been assumed to cause the same or similar impacts as testing of component as described for the test life cycle phase.

Exhibit 4-2. Analysis of Impacts of Development Phase Activities

Activity	Source of Impact	Impacts Analysis
Planning/Budgeting	None	Routine activity categorically excluded; not further analyzed
Research and Development	None	Routine activity categorically excluded; not further analyzed
Systems Engineering	None	Routine activity categorically excluded; not further analyzed

Exhibit 4-2. Analysis of Impacts of Development Phase Activities

Activity	Source of Impact	Impacts Analysis
Site Preparation and Construction	Construction or modifications necessary to support component prototype development	Section 4.1.1.9 Support Assets - Infrastructure
Maintenance or Sustainment	Activities related to hardware or software upgrades or maintenance of component prototypes	Routine activity categorically excluded or analyzed in previous NEPA documents and found to have no significant impact. Rationale presented in Section 4.1.1.9 Support Assets - Infrastructure
Manufacturing of Prototypes	Manufacturing of component prototypes	Routine activity categorically excluded or analyzed in previous NEPA documents and found to have no significant impact. Rationale presented in Section 4.1.1.10 Support Assets - Test Assets
Testing of Component Prototypes	Activities related to activation or use of the component prototypes	Sections 4.1.1.1 Weapons - Lasers, 4.1.1.2 Weapons - Interceptors, 4.1.1.3 Sensors - Radar, 4.1.1.4 Sensors - Infrared and Optical, 4.1.1.5 Sensors - Laser, 4.1.1.6 C2BMC - Computer Terminals and Antennas, 4.1.1.7 C2BMC - Underground Cable, 4.1.1.8 Support Assets - Equipment, 4.1.1.9 Support Assets - Infrastructure, 4.1.1.10 Support Assets - Test Assets
Tabletop Exercises	None	Routine activity categorically excluded; activity not further analyzed

Test Phase Activities

Test life cycle phase activities were considered in two distinct analyses; one focused on the components and their individual test activities, and the other focused on System Integration Testing which could include multiple components with one or more attempted intercepts to test system capability and effectiveness in increasingly robust and realistic test scenarios.

BMDS *component testing activities* assumed to have potential impacts on the environment were considered for each component as shown in Exhibit 4-3. Some of the activities that comprise the test life cycle phase are unique to individual components. For example launch/flight is relevant for interceptors and targets but not for C2BMC. Test life cycle phase activities are specific to each component. Therefore, Exhibit 4-3 is presented by component and shows those specific activities that were determined to have the potential for impact. Other activities such as site preparation and construction are not unique to individual components and are therefore considered collectively in Support Assets. The impacts associated with a target intercept involving either laser or interceptor weapons are addressed as part of Test Integration.

Exhibit 4-3. Analysis of Impacts of Test Life Cycle Phase Activities

Component	Activity	Source of Impact	Impacts Analysis
Weapons-Laser	Manufacturing of Test Articles	Manufacturing/assembly of laser components and chemicals	Routine activity categorically excluded or analyzed in previous NEPA documents and found to have no significant impact. Rationale presented in Section 4.1.1.10 Support Assets - Test Assets
	Site Preparation and Construction	Construction or modifications necessary to support laser use/firing	Section 4.1.1.9 Support Assets - Infrastructure

Exhibit 4-3. Analysis of Impacts of Test Life Cycle Phase Activities

Component	Activity	Source of Impact	Impacts Analysis
	Transportation	Transport of the laser and chemicals to appropriate location	Routine activity categorically excluded or analyzed in previous NEPA documents and found to have no significant impact. Rationale presented in Section 4.1.1.8 Support Assets - Equipment
	Activation	Firing the laser	Section 4.1.1.1 Weapons - Lasers
Weapons-Interceptor	Manufacturing of Test Articles	Manufacturing interceptor components and propellants	Routine activity categorically excluded or analyzed in previous NEPA documents and found to have no significant impact. Rationale presented in Section 4.1.1.10 Support Assets - Test Assets
	Site Preparation and Construction	Construction or modifications necessary to support launch	Section 4.1.1.9 Support Assets - Infrastructure
	Transportation	Transport of the booster, kill vehicle, and propellants to the launch location	Routine activity categorically excluded or analyzed in previous NEPA documents and found to have no significant impact. Rationale presented in Section 4.1.1.8 Support Assets - Equipment
	Prelaunch	Assembly and fueling of the booster or kill vehicle, as appropriate	Section 4.1.1.2 Weapons - Interceptors

Exhibit 4-3. Analysis of Impacts of Test Life Cycle Phase Activities

Component	Activity	Source of Impact	Impacts Analysis
	Launch/Flight	Ignition of rocket motors and flight of boosters or separation of kill vehicle and subsequent flight along its trajectory	Section 4.1.1.2 Weapons - Interceptors
	Postlaunch	Clean up or debris recovery, if required	Section 4.1.1.2 Weapons - Interceptors
Sensors	Manufacturing	Manufacturing/assembly of the sensor hardware and software	Routine activity categorically excluded or analyzed in previous NEPA documents and found to have no significant impact. Rationale presented in Section 4.1.1.10 Support Assets - Test Assets
	Site Preparation and Construction	Construction or modifications necessary to support sensor use	Section 4.1.1.9 Support Assets - Infrastructure
	Transportation	Transport of the sensor to appropriate location	Routine activity categorically excluded or analyzed in previous NEPA documents and found to have no significant impact. Rationale presented in Section 4.1.1.8 Support Assets - Equipment
	Activation	Use of the sensor	Sections 4.1.1.3 Sensors - Radar, 4.1.1.4 Sensors - Infrared and Optical, and 4.1.1.5 Sensors - Laser

Exhibit 4-3. Analysis of Impacts of Test Life Cycle Phase Activities

Component	Activity	Source of Impact	Impacts Analysis
C2BMC	Manufacturing	Assembly of associated hardware and software	Routine activity categorically excluded or analyzed in previous NEPA documents and found to have no significant impact. Rationale presented in Section 4.1.1.10 Support Assets - Test Assets
	Site Preparation and Construction	Construction or modification for computer terminals, antennas, and underground cable trenching	Section 4.1.1.9 Support Assets - Infrastructure
	Transportation	Transport of C2BMC to appropriate location	Routine activity categorically excluded or analyzed in previous NEPA documents and found to have no significant impact. Rationale presented in Section 4.1.1.8 Support Assets - Equipment
	Activation	Use of computer terminals, antennas, and underground cable	Sections 4.1.1.6 C2BMC - Computer Terminal and Antennas, 4.1.1.7 C2BMC - Underground Cable

Exhibit 4-3. Analysis of Impacts of Test Life Cycle Phase Activities

Component	Activity	Source of Impact	Impacts Analysis
Support Assets-Support Equipment	Manufacturing	New or major modification of existing support equipment	Routine activity categorically excluded or analyzed in previous NEPA documents and found to have no significant impact. Rationale presented in Section 4.1.1.10 Support Assets - Test Assets
	Operational Changes	Implementation of new operating parameters of existing support equipment	Section 4.1.1.8 Support Assets - Equipment
	Site Preparation and Construction	New construction or major modification of existing infrastructure	Section 4.1.1.9 Support Assets - Infrastructure
	Transportation	Transport of support equipment	Routine activity categorically excluded or analyzed in previous NEPA documents and found to have no significant impact. Rationale presented in Section 4.1.1.8 Support Assets - Equipment
Support Assets-Infrastructure	Site Preparation and Construction	Construction or modification of infrastructure	Section 4.1.1.9 Support Assets - Infrastructure

Exhibit 4-3. Analysis of Impacts of Test Life Cycle Phase Activities

Component	Activity	Source of Impact	Impacts Analysis
Support Assets- Test Assets	Manufacturing	Assembly of hardware/software associated with the test sensor	Routine activity categorically excluded or analyzed in previous NEPA documents and found to have no significant impact. Rationale presented in Section 4.1.1.10 Support Assets - Test Assets
	Site Preparation and Construction	Construction or modifications necessary to support the test sensor or launch	Section 4.1.1.9 Support Assets - Infrastructure
	Transportation	Transport of the sensor, booster and propellants to the test location	Routine activity categorically excluded or analyzed in previous NEPA documents and found to have no significant impact. Rationale presented in Section 4.1.1.8 Support Assets - Equipment
	Activation	Use of the test sensor in a test event	Section 4.1.1.3 Sensors - Radar, 4.1.1.4 Sensors - Infrared and Optical, and 4.1.1.5 Sensors - Laser
	Prelaunch	Assembly and fueling of the booster as appropriate	Section 4.1.1.2 Weapons - Interceptors

Exhibit 4-3. Analysis of Impacts of Test Life Cycle Phase Activities

Component	Activity	Source of Impact	Impacts Analysis
	Launch/Flight	Ignition of rocket motors, separation from launch platform, and flight of the boosters or separation of the target object and subsequent flight along its trajectory	Section 4.1.1.2 Weapons - Interceptors
	Use of Countermeasures, Simulants or Drones	Use and deployment of various countermeasures, simulants or drones to support testing	Section 4.1.1.10 Support Assets - Test Assets
	Postlaunch	Clean up or debris recovery to include launch platform, countermeasures, and simulants, if required	Section 4.1.1.2 Weapons - Interceptors

The operating environments in which test activities occur (i.e., land, sea, air, and space) were determined to influence the environmental impacts only for laser activation, launch/flight activities, sensor activation, and activation of C2BMC. Therefore, these activities were also considered by operating environment in analyzing their environmental effects. Individual component tests are needed to demonstrate the functionality of BMDS technology. Potential environmental consequences of component tests are discussed in previous NEPA documentation and in their respective sections in this PEIS.

BMDS *System Integration Testing activities* would occur at the system level. System Integration Tests evaluate the ability of various component configurations to work together. System Integration Testing would be used to assess the ability of BMDS components to work interoperably and to meet the required functional capabilities of the BMDS as a system and to demonstrate performance.

System Integration Tests would integrate existing and planned components such as sensors, weapons, and C2BMC. This PEIS assesses the potential for environmental impacts of integrated BMDS testing activities under Alternatives 1 and 2. Test integration activities would involve land-, sea-, and air-based operating environments for weapons; and land-, sea-, air- and space-based operating environments for sensors, C2BMC, and support assets for Alternative 1. Assessment of Alternative 2 considers

only the additional impacts of proposed space-based operating environment for interceptors.

System level tests would include modeling, simulation, and analysis; integrated missile defense wargames; MDIE; integrated GTs; and SIFTs. A description of each type of test is provided in Exhibit 2-22.

The analysis of intercept impacts includes discussion of the impact of debris from an intercept. Depending on the location used for testing or deployment of weapons, debris may impact either inland or in marine environments. Therefore, impacts from postlaunch activities involving intercepts have been subcategorized based on where intercept debris would be likely to impact. For purposes of this PEIS, it was assumed that the debris impacts from any single intercept would occur within a single receiving environment, either on land or in water.

Deployment Phase Activities

Deployment phase activities with the potential for impacts on the environment would include manufacturing (production) of components, site preparation and construction, use of human services, transportation of components to the deployment site, testing (prelaunch, launch/flight, activation, postlaunch), training, and maintenance or sustainment of the components (operation and maintenance, upgrades, and service life extension). The environmental impacts associated with maintenance including hardware and software upgrades and service life extension are routine activities that are generally categorically excluded and are not analyzed in this PEIS. The environmental impacts associated with manufacturing, site preparation and construction, and transportation, and human services are routine activities that are generally categorically excluded or are analyzed in previous NEPA documents and found to have no significant impact. The rationale for why they are not analyzed in this PEIS is provided in Support Assets. The environmental impacts associated with training would be similar to the use of the component as described under the testing life cycle activity.

Future deployment of BMDS components would occur at times and places where the deployed component would provide the most useful defensive capability to counter existing or emerging threats. This could include sites outside the continental U.S. The environmental impacts of deployment at specific locations would need to be considered in subsequent site-specific NEPA analyses tiered from this PEIS. The activities and associated impacts from deployment phase activities are presented in Exhibit 4-4.

Exhibit 4-4. Analysis of Impacts of Deployment Phase Life Cycle Activities

Activity	Source of Impact	Impacts Analysis
Manufacturing	Manufacturing (production) of the component	Routine activity categorically excluded or analyzed in previous NEPA documents and found to have no significant impact. Rationale presented in Section 4.1.1.10 Support Assets - Test Assets
Site Preparation and Construction	Construction or modifications necessary to support component deployment	Section 4.1.1.9 Support - Infrastructure
Transportation	Transporting component to deployment location	Routine activity categorically excluded or analyzed in previous NEPA documents and found to have no significant impact. Rationale presented in Section 4.1.1.8 Support Assets – Equipment
Testing	Activities related to prelaunch, launch/flight, postlaunch, or activation of the component	Testing of components would be the same as or similar to the use of the component as described under the testing lifecycle activity
Maintenance or Sustainment	Activities related to hardware or software upgrades	Activities related to prelaunch, launch/flight, postlaunch, or activation of the component
Upgrades	No source of impact	Routine activity categorically excluded; activity not further analyzed
Training	Activities related to prelaunch, launch/flight, postlaunch, or activation of the component	Testing of components would be the same as or similar to the use of the component as described under the testing life cycle activity
Use of Human Services	Activities related to increasing the presence of staff at deployment sites	The use of human services is more appropriately addressed in site specific documentation. Rationale presented in Section 4.1.1.9 Support Assets - Infrastructure

Exhibit 4-4. Analysis of Impacts of Deployment Phase Life Cycle Activities

Activity	Source of Impact	Impacts Analysis
Service Life Extension	No source of impact	Routine activity categorically excluded; activity not further analyzed

Decommissioning Phase Activities

Typical decommissioning phase activities would include demilitarization and disposal or replacement of the component. Activities associated with decommissioning may include recycling and disposal of hazardous materials. The activities associated with decommissioning are presented in Exhibit 4-5. The environmental impacts associated with decommissioning of specific components would be more appropriately addressed in subsequent tiered environmental analyses.

Exhibit 4-5. Analysis of Impacts of Decommissioning Phase Life Cycle Activities

Activity	Source of Impact	Impacts Analysis
Demilitarization	Destruction of offensive or defensive systems capability which may include disposal or detonation of hazardous materials (propellants, batteries, etc)	A roadmap for considering decommissioning impacts is provided; an analysis would be more appropriately addressed in subsequent tiered environmental analyses.
Disposal	Materials to be disposed may include hazardous materials and hazardous waste (propellants, coolants, batteries, etc.)	A roadmap for considering decommissioning impacts is provided; an analysis would be more appropriately addressed in subsequent tiered environmental analyses.

A roadmap for considering impacts of decommissioning for each component has been developed and is provided below. A Government depot or contractor may accomplish demilitarization and disposal of the components. The military service responsible for managing each piece of equipment would initiate the demilitarization and disposal process. Normally, each individual piece of equipment would have disposition instructions that have been prepared by its development contractor or project office in the case of MDA. These instructions identify the hazardous materials contained in the equipment item. A copy of the disposition instructions would be provided to the depot or contractor performing the demilitarization and disposal. It would be the responsibility of the depot or contractor to identify, remove, segregate, package, and document all hazardous materials in the item. In the case of a depot, disposal of hazardous materials

would be through Government channels as described below. When a contractor is utilized, hazardous materials disposal would be processed through commercial channels in compliance with all applicable Federal, state, and local laws.

When a depot performs the demilitarization and disposal functions, disposal of hazardous and nonhazardous materials would be through a Defense Reutilization and Marketing Office (DRMO). The DRMO would physically accept and process all property that falls within the DRMO area of responsibility. The DRMO would be responsible for disposing of hazardous materials in accordance with applicable Federal, state, and local laws, utilizing best management practices.

Components would be transported to demilitarization and disposal locations by the method appropriate to their location and military sensitivity. Transportation to contiguous land areas could be by ground (truck or rail) in accordance with DOT, state and local transportation and safety regulations and procedures. Transportation from, or to, island locations would be by aircraft in accordance with DOT and U.S. Air Force regulations and procedures, or by U.S. Navy, U.S. Army, or commercial ships in accordance with U.S. Coast Guard and Maritime Administration requirements and any other applicable regulations and procedures.

Potential decommissioning activities for weapons, sensors, C2BMC, and support assets are discussed below.

Decommissioning of ***weapons*** components would involve transferring the equipment to other uses, as described above, or demilitarization in accordance with the requirements of DoD 4160.21-M-1, Appendix 4 "*Demilitarization Requirements for Munitions List Items*." Specific requirements are found in DoD 4160.21-M-1, Appendix 4, Category IV, "*Launch Vehicles, Guided Missiles, Ballistic Missiles, Rockets, Torpedoes, and Components*," and DoD 4160.21-M-1, Appendix 4, Category V "*Military Explosives, Solid and Liquid Propellants, Bombs, Mines, Incendiary Agents, and Their Constituents*." Because the BMDS does not include nuclear weapons, the requirements of DoD 4160.21-M-1, Appendix 4, Category XVI, "*Nuclear Weapons Design and Test Equipment*," would not apply to the decommissioning of weapons components. Examples of potential decommissioning plans for missiles (interceptors and targets) are included below.

Decommissioning of missiles would first require the removal and proper disposal of liquid, solid, or hybrid (liquid and solid combination) propellants from the booster(s). Where possible, propellants would be recovered and reused. Aging motors that contain flaws would likely be decommissioned using open detonation. Some liquid fueled missiles are fueled only before a scheduled launch; others are pre-fueled. In addition, the kill vehicle on an interceptor missile typically uses liquid hypergolic propellants and some solid propellants for its divert and attitude control system. Liquid propellants would need to be emptied before disassembly of the missile could occur. Solid rocket

propellant would be removed for reclamation or burning in a controlled environment, such as an incinerator. Where practicable, incineration or closed burning of rocket propellant would be performed. Most of the acid and particulates ejected during the burn would be collected in plume scrubber water. This water would be treated for acceptance by a publicly owned (or federally owned) water treatment works or discharged in accordance with a National Pollutant Discharge Elimination System (NPDES) permit.

Decommissioning of lasers would require the removal and proper disposal or neutralization of chemical laser fuels from the storage facilities. Where possible, these chemicals would be recovered and reused. Decommissioning of the aircraft would be conducted in accordance with DOD 4160.21-M-1, Appendix 4, Category III, "*Military Aircraft (Combat, Tactical Air Vehicles) Spacecraft and Associated Equipment*" and other applicable requirements. Decommissioning activities for other laser components would be conducted as appropriate in accordance with applicable regulations.

The MDA would develop new ***sensor*** equipment in addition to using a variety of existing equipment. Equipment intended only for testing purposes and not for use in the BMDS architecture would be returned to the responsible military service for continuation of its original duties. Any decommissioning activities for this equipment would be carried out by the responsible military service. Equipment would be demilitarized in accordance with DoD 4160.21-M-1, Appendix 4, Category XII "*Fire Control, Range Finder, Optical, and Guidance and Control Equipment.*"

The decommissioning of sensors, equipment, and facilities would include the recycling/reuse or disposal of residual materials and unused products associated with the antennae, electronic, cooling, and power units. These products would include but are not limited to lubricants, coolants, batteries, and fuels. These materials would be decommissioned in accordance with Chapter 10, Environmentally Regulated and Hazardous Property, of the (DoD) Directive 4160.21-M, *Defense Reutilization and Disposal* and any applicable Federal, state, and local regulations and requirements. Reusable materials from sensors, such as metals, would be recovered. Other materials would be shredded and recycled or disposed of, as appropriate.

Sea-based sensors such as the SBX radar use a MOSS CS50 platform to support a radar support structure and radome. The CS50 platform was designed for use in oil exploration. After the sea-based radar system is removed, the platform could be converted to another MDA use (launch platform, test or deployed radar platform, etc.), transferred to a military service, or sold. If another use of the platform is not feasible, DoD would dismantle the platform and dispose of the materials by recycling, reuse, or discarding it in appropriate waste management facilities. DoD could also consider sinking the platform at sea after all toxic materials are removed, to provide a foundation for marine life.

Space-based sensors would be decommissioned by being abandoned in orbit, parked in a higher orbit, deorbited, or retrieved. Space-based sensors left in orbit that have non-BMDS utility could be transferred to alternate uses if economically feasible and the alternate use would not affect national security. Potential alternate uses include monitoring rocket launches and aircraft flights. DoD would make decisions on the disposition of the space-based components based on the stability of their orbits, the costs and risks of deorbiting or retrieval, the remaining useful life of the equipment, and potential for alternate uses.

Components could be retrieved from orbit and brought back to Earth for decommissioning and demilitarization if allowing them to remain in orbit poses unacceptable risks. Components abandoned in orbit would continue to orbit until gravitational and atmospheric drag cause the component to deorbit and reenter the atmosphere where it would either burn up or fall to Earth. Potential risks include danger to populations on Earth or the loss of equipment sensitive to national security. U.S. Space Command tracks orbits of satellites and space debris, and provides reentry predictions. When the predictions indicate a risk to land areas, a controlled deorbit would be considered to ensure reentry occurs over ocean areas. Parking the component in a higher orbit would increase the time before deorbit. Demilitarization of space-based components would be conducted in accordance with DoD 4160.21-M-1, Appendix 4, Category VIII, "*Military Aircraft (Combat, Tactical Air Vehicles), Spacecraft and Associated Equipment*," Category XI, "*Military and Space Electronics,*" and Category XV, "*Spacecraft Systems and Associated Equipment.*"

The MDA would develop new ***C2BMC*** equipment as well as use a variety of existing equipment. As technology advances and the needs of the BMDS evolve, multiple upgrades of C2BMC hardware and software are likely. DoD would be responsible for decommissioning activities in accordance with appropriate requirements for the specific C2BMC equipment.

Support assets include fixed facilities and mobile equipment as well as test assets including the test bed, test sensors, and targets. This discussion of decommissioning activities focuses on fixed and mobile equipment. Components that make up the test bed, test sensors and targets are addressed previously under decommissioning weapons and sensors.

Fixed facilities may include DoD-owned buildings located on ranges, installations, or related real estate such as islands temporarily used for BMDS purposes. Government contractor facilities include such sites as the Nevada Test Site and Sandia National Laboratory in New Mexico. Privately owned facilities include those owned by companies manufacturing components for the BMDS. Exhibit 4-6 describes decommissioning activities for fixed facilities.

Exhibit 4-6. Decommissioning Activities for Fixed Facilities

<table>
<tr><th colspan="2" rowspan="3">Fixed Facilities</th><th colspan="4">Decommissioning Activities</th></tr>
<tr><th colspan="3">Left in Place</th><th>Disposed</th></tr>
<tr><th>Mission Realignment</th><th>Return to Owners/Host Facility</th><th>Transfer Title to New Owner</th><th>Transfer Land Title to New Owner</th></tr>
<tr><td rowspan="3">Buildings</td><td>DoD-owned</td><td>X</td><td></td><td>X</td><td>X</td></tr>
<tr><td>Government Contractor</td><td></td><td>X</td><td></td><td></td></tr>
<tr><td>Private</td><td></td><td>X</td><td></td><td></td></tr>
<tr><td rowspan="5">Launch Locations</td><td>DoD Launch Pads/Runways</td><td>X</td><td></td><td>X</td><td>X</td></tr>
<tr><td>Silos</td><td>X</td><td></td><td></td><td></td></tr>
<tr><td>Other Government</td><td></td><td>X</td><td></td><td></td></tr>
<tr><td>Private</td><td></td><td>X</td><td></td><td></td></tr>

<tr><td rowspan="3">Utilities</td><td>Water/Sewer Systems</td><td>X</td><td>X</td><td>X</td><td>X</td></tr>
<tr><td>Power Plants (gas and coal fired)</td><td>X</td><td>X</td><td>X</td><td>X</td></tr>
<tr><td>Fiber optic and Other Cables</td><td>X</td><td>X</td><td>X</td><td>X</td></tr>
</table>

Fixed buildings or structures could include those used for testing purposes, deployment, or both. As described above, the MDA would evaluate DoD-owned buildings for continued or adaptive use by the DoD or other U.S. Government agencies. Following the decision to decommission, any necessary decontamination activities would be performed. Buildings owned by the DoD that are not assigned new missions could be sold and the title transferred to the new owner. Any space devoted to BMDS activities in government contractor or contractor facilities would be returned to the host installation. All BMDS-related equipment would be removed according to decommissioning regulations.

Other fixed BMDS components include launch pads, in-ground missile silos, and runways. Launch pads, silos, and runways located at the various DoD installations, upon completing their BMDS mission, might be assigned new DoD missions and might not

need to be decommissioned. Other government launch facilities include those run by the NASA such as Kennedy Space Center.

Private facilities include those owned by states or private organizations such as the KLC, which is run by the Alaska Aerospace Development Corporation. Upon termination of any BMDS testing or deployment activities conducted on the grounds of these facilities, any private assets and components used by MDA to support testing or deployment would be returned to full control of the host installation or otherwise disposed per existing contractual agreement.

Utilities installed in new or existing facilities as part of the BMDS mission would include water/sewer systems and fiber optic or other cables. Depending on the decommissioning decision related to any related DoD-buildings or structures, utilities could be left in place if the potential existed to use them for future DoD or other entity purposes. They would either be passed to the existing owner or host installation if installed on contractor property. Should a related structure be transferred to a new owner, utilities likely would be left in place.

The scope of the BMDS includes some testing and potential deployment at locations abroad. Decommissioning options for international buildings, launch locations, or utilities would be the same as for domestic locations. However, it is expected that the extent of the BMDS presence in other countries would be less than in the continental U.S.

Mobile land-based components include transportation vehicles (e.g., trucks, vans and trains) and missile launchers. Equipment removed from the mobile land-based components would be refurbished and transferred to an alternate use, demilitarized, or dismantled and disposed. Upon completion of their BMDS mission, DoD-owned transportation vehicles would either be assigned another mission or be disposed or sold by DoD. Vehicles owned by government contractors or private companies would be returned to their original owners following any decontamination required. Missile launchers, such as the THAAD mobile launcher, which uses a U.S. Army Heavy Expanded Mobility Tactical Truck with Load Handling System Truck would be disassembled and disposed. Some missile launcher interiors were coated with a specialized paint containing chromium. Disposal of chromium contaminated paint dust or water used in the removal of the paint would require disposal according to applicable Federal and State regulations.

Following the decision to decommission, any necessary decontamination activities would be performed. Land areas would be restored to previous conditions or other condition compatible with planned land use of the site. Demilitarization of land-based components would be conducted in accordance with the applicable category of DoD 4160.21-M-1, Appendix 4 "*Demilitarization Requirements for Munitions List Items,*" or other applicable requirements. Disposal of land-based components would involve the removal

of BMDS equipment and assets. The components could be left in place and a new mission assigned for them. The components could be returned to the owners of the host facility (if not DoD-owned) or transferred to new owners. Transfer would occur under an interagency agreement, memorandum of understanding, lease agreement, or other agreement.

The MDA would decommission the three current airborne sensor aircraft (HALO I, HALO II, and Widebody Airborne Sensor Platform [WASP]) and future airborne sensors when they are no longer needed to support the MDA testing program. MDA would remove the sensors and other government property from the aircraft and then decommission the aircraft by transferring to another government agency, selling as excess government property, salvaging usable parts, or mothballing at a government airfield. MDA is currently purchasing the HALO aircraft.

Under the Measurements Program, countermeasures would be recycled or reused for alternate DoD missions. Simulants and submunitions used for lethality testing also would be recycled or reused, where possible, or disposed in accordance with applicable regulations.

4.1 Alternative 1 – Implement BMDS Using Land-, Sea-, and Air-Based Weapons Platforms

4.1.1 BMDS Components

The following analyses are organized by component and subcomponent. The analyses are specific to each resource area (i.e., air quality, airspace, biological resources, geology and soils, hazardous materials and hazardous waste, health and safety, noise, transportation, and water resources) based on the impacts from the life cycle activities associated with each component. Where activities that are not unique to the life cycle phase or component and have the potential to result in similar environmental impacts, they were addressed together to eliminate redundancy. Where activities that are not unique to an individual component and have the potential to result in similar environmental impacts, they were addressed together to eliminate redundancy. As previously discussed under the Description of Life Cycle Activities and Development Phase Activities, manufacturing, site preparation and construction, and transportation of components are discussed under Support Assets. Because such activities would be performed by or on support assets, the impacts from manufacturing, site preparation and construction, and transportation activities associated with each BMDS component are discussed under Support Assets.

4.1.1.1 Weapons - Lasers

As described in Exhibit 4-3, the analysis for lasers is based upon impacts from the activation of the laser.

Air Quality

Operation of a COIL would result in gaseous emissions of water vapor, CO_2, oxygen, helium, nitrogen (N_2), ammonia, chlorine, H_2, and iodine. Liquid hydrogen peroxide also would be released. Ammonia and chlorine are hazardous substances. At altitude, the gases produced by the laser are exhausted into the air. During activation from land and sea platforms (assuming that sea-based laser activation was done under the same test conditions used for ground testing), most of the gaseous emissions produced by the laser would be captured in an air pollution scrubber. The estimated quantities released and scrubbed (for laser activation from land and sea platforms) in a single lasing event are shown in Exhibit 4-7. (U.S. Department of the Air Force, 1997b)

Exhibit 4-7. Estimated In-Flight COIL Gaseous Emissions in Kilograms (Pounds)*

Chemical	Total Quantity Produced per Laser Activation Kilograms (Pounds)	Quantity of Emissions Released to Atmosphere for Air Platform Laser Activation Kilograms (Pounds)	Quantity of Emissions Captured in Solution by Scrubber for Land and Sea Platform Laser Activation Kilograms (Pounds)	Quantity of Emissions Released to Atmosphere for Land and Sea Platform Laser Activation Kilograms (Pounds)
Ammonia (recovered in closed-loop system)	N/A	N/A	N/A	N/A
Carbon dioxide	761 (1,677)	761 (1,677)	0 (0)	761 (1,677)
Chlorine	29 (63)	29 (63)	24 (53)	5 (10)
Helium/N_2	86 (190)	86 (190)	0 (0)	86 (190)
H_2	20 (43)	20 (43)	0 (0)	20 (43)
Iodine	10 (23)	10 (23)	9 (20)	1 (3)
Oxygen	219 (483)	219 (483)	0 (0)	219 (483)
Water	1,389 (3,063)	1,389 (3,063)	1,181 (2,603)	209 (460)

*Calculations subject to rounding
Source: U.S. Department of the Air Force, 1997b

Land and Sea Operating Environments

Impacts to air quality from the activation of the COIL from land or sea platforms would be minimal, given the short duration of the laser operation (less than 30 seconds [U.S. Department of the Air Force, 1997b]) and the propensity of hot gases in the emission

cloud to rise. Because a small amount of chlorine may remain after scrubbing and be released to the atmosphere, rain within two hours of laser activation could cause hydrochloric acid to form and be deposited in small quantities. (U.S. Department of the Air Force, 1997b)

Under high humidity or rainy conditions, chlorine exhaust would be removed from the atmosphere in a shorter amount of time, as the chlorine is converted to hydrochloric acid. Because of their humid climates hydrochloric acid would likely be produced as a result of laser activation in a number of biomes including Arctic Tundra Coastal, Sub-Arctic Taiga Coastal, Deciduous Forest, Deciduous Forest Coastal, and Mountain Biomes. In addition, hydrochloric acid could be produced in the Sub-Arctic Taiga, Chaparral, Grasslands, and Savanna Biomes when cool and humid conditions exist during laser activation activities. The strong winds in the BOA would support the rapid dispersion of emissions. Given the dry conditions in the Desert Biome, it is unlikely that chlorine would be converted to hydrochloric acid. The Tropical Coastal Biome is generally humid but the temperatures do not cool enough to convert any chlorine produced as a result of laser activation to hydrochloric acid.

Hydrochloric acid produced as a result of the interaction between laser emissions and moisture in the air has the potential to produce impacts on biological resources, including plants and aquatic animals, and water quality. The extent and relative significance of the impact depends on the site-specific receptors present at the location. However activation of lasers, in general, would result in a small amount of chlorine being converted to hydrochloric acid, which would be further diluted by rain water.

Air Operating Environment

Impacts to air quality from laser activation from air platforms would result in similar impacts to those discussed above for land and sea operating environments. However, the potentially harmful substances would be released at approximately 12,192 meters (40,000 feet) above the Earth’s surface and therefore, would be less likely to affect ground-level air quality. High exhaust gas temperature would result in positive buoyancy, allowing the exhaust emissions to rise quickly. The high exit velocity of the exhaust gases and the chemical composition of the exhaust would further increase the rate of dispersion and increase the altitude at which dispersion occurs. Therefore, the gases would not accumulate in any significant quantities, and no significant impact to air quality would be expected due to activation of lasers from air operating environments. (U.S. Army Space and Strategic Defense Command, 1998b)

If the COIL were operating in the upper reaches of the troposphere and in the lower stratosphere (up to 12 kilometers [7 miles]), chlorine exhaust emissions would be converted quickly to forms that dissolve in water and would be removed from the

atmosphere. (U.S. Department of the Air Force, 1997b) Chlorine may be converted to hydrochloric acid, which has the potential to increase the acidity of precipitation.

Ammonia is water-soluble and would dissolve in water and be removed from the atmosphere in approximately 20 days. (Seinfeld, 1986, as referenced in U.S. Department of the Air Force, 1997b) Emissions of chlorine and ammonia from the COIL would be insignificant compared to the amount of chlorine and ammonia released by industrial sources every year. (U.S. Department of the Air Force, 1997b) Emissions of CO_2 associated with operation of the COIL would be minimal and would not be expected to contribute significantly to global warming.

Chlorine is capable of destroying ozone, which is beneficial in the upper atmosphere for blocking harmful rays from the sun. If the emissions occur in the lower stratosphere (above the troposphere), the local concentration of chlorine would increase approximately 35 percent for a short period of time (less than 24 hours). (MDA, 2003a) The increased levels would return to background levels within several hours as atmospheric winds disperse the chlorine. Operation of the COIL in the stratosphere would be spread out over time, thereby eliminating the possibility for local, cumulative effects.

In the event that the aircraft is unable to land at the appropriate landing location, it may be necessary to jettison aircraft fuel and laser chemicals. The laser chemicals could be discarded at a minimum altitude of at least 4,572 meters (15,000 feet). Chemical dispersion modeling has shown that release of liquids used by the COIL at this altitude will not reach the ground and would be diluted in the atmosphere. (MDA, 2003a) Laser chemicals include hydrogen peroxide, ammonia, chlorine, helium, N_2, and iodine. Iodine would be carried as a solid and would not be jettisoned. If the chemicals could not be released at or above this height, the laser chemicals would remain onboard until the air operations could be grounded.

B-747 aircraft would be used for air-based lasers. B-747 fire suppression systems contain 150 kilograms (330 pounds) of Halon 1301 and 9 kilograms (20 pounds) of Halon 1211, both of which are Class I ozone-depleting substances that contribute to ozone depletion when released to the atmosphere. Use of Halon CFC fire suppression systems would take place only in emergency situations, which would be extremely rare. In the case of a fire, the amount of Halon released would be small compared to the amount of CFCs already present in the atmosphere. Fire suppression substitutes are being developed and evaluated and may be available for future operation of lasers in an air operating environment.

Airspace

Land and Sea Operating Environments

Ground testing of HELs that would occur in indoor facilities would have no effect on airspace in any biome considered in this PEIS. Outdoor activation of lasers from land or sea operating environments could impact the use of airspace. Close coordination with the FAA ARTCC and relevant military installations with responsibility for airspace management would minimize the potential for any adverse impacts on airspace use. Activation of lasers would occur in cleared airspace within designated airspace areas.

Air Operating Environment

Laser activation from air platforms would occur at an altitude of approximately 12,192 meters (40,000 feet). The laser beam would be pointed horizontally or upward. Activation of lasers would occur in cleared airspace within designated airspace use. Close coordination with the FAA ARTCC and relevant military installations with responsibility for airspace management would minimize the potential for any adverse impacts on airspace use.

Biological Resources

Land and Sea Operating Environments

Ammonia and chlorine produced from the land- and sea-based operation of the COIL could harm underlying vegetation and wildlife. Chlorine is known to injure plant leaves and affect wildlife. Direct effects could include discoloration, foliage loss, and changes in species composition. (U.S. Department of the Air Force, 1997b) Birds flying through the exhaust plume might be exposed to concentrations of hydrochloric acid, which could irritate eye and respiratory tract membranes. However, the high temperature of the emissions, the noise produced by support equipment, and visual cues of the emissions would likely cause birds to fly away from the launch area and therefore, prevent them from being exposed to the chlorine exhaust.

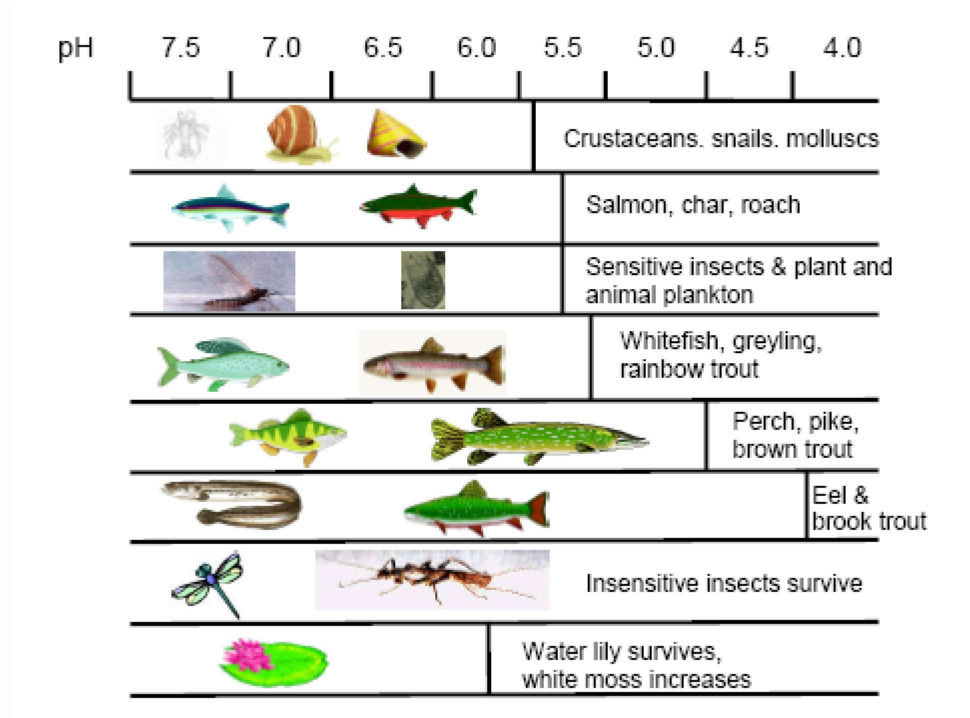
Furthermore, studies involving a variety of laser projects in New Mexico indicate that cumulative impacts to wildlife from laser propagation are negligible. (U.S. Army Corps of Engineers, 1989)

The presence of hydrochloric acid in freshwater bodies may cause temporary increases in water acidity and could alter the regular functioning of the aquatic ecosystem. However, saltwater tends to neutralize acid; therefore, significant acidification does not occur in the ocean and most estuaries, where freshwater and saltwater combine. (EPA, 2003g)

Nonetheless, deposition of HCl into the ocean may create a temporary hazard to marine wildlife. Special consideration should be given to any potential impacts to Essential Fish Habitat and efforts, such as scrubbing emissions, should be made to mitigate the impacts. Once deposited, hydrochloric acid would be diluted and dispersed by the receiving waters. Impacts would be limited to a small area surrounding the point of contact, as the waves and ocean currents would inhibit widespread deleterious effects to marine wildlife.

In environments where there are water bodies, including bogs, fens, marshes, shallow lakes, rivers, and wetlands, chlorine would be converted to an acidic form, where it could alter the pH of the water body. The activation of lasers would not be expected to cause a significant increase in water acidity; however, site-specific analyses would be needed to consider specific impacts to individual locations. In general, the Sub-Arctic Taiga Coastal, Deciduous Forest, Deciduous Forest Coastal, and Mountain Biomes are likely to have water bodies that could be affected by an increase in acidity. Much of the Deciduous Forest Biome is already affected by acidic precipitation; therefore, its regional flora and fauna may not be able to tolerate additional acidic toxicity from laser activation. The presence of hydrochloric acid in prairie potholes in the Grasslands Biome could lower the pH of the water (making it more acidic), which could have a negative effect on waterfowl, shorebirds, and waterbirds that stopover during migration and/or breed in the waters. Mountain lakes are particularly sensitive to the effects of acidification because they have soft water, which does not neutralize acid readily. Furthermore, mountain lake ecosystems quickly show the effects from an external input. As a result, some mountain lake wildlife might not be able to adapt to a lower pH level quickly enough to absorb the effects of increased water acidity without harm. (PECO/COPERNICUS, 1999) Other biomes including Arctic Tundra Coastal, Sub-Arctic Taiga, Chaparral Coastal, Desert, Tropical Coastal, BOA, and Savanna are unlikely to experience increased acidity in surface waters either because hydrochloric acid is unlikely to be produced as a result of laser activation or because surface water is uncommon in these areas. An increase in acidity could affect pH-sensitive aquatic species, as shown in Exhibit 4-8. This has the potential to adversely affect biodiversity; however, this potential affect would be limited to the areas surrounding the laser activation site. The overall increase in acidity, and therefore, the impact to biodiversity would not be expected to be significant.

Exhibit 4-8. Freshwater Species Tolerance to Acidity



Source: Atmosphere, Climate and Environment Information Programme, 2003

Species including birds, pinnipeds, and sea otters are less likely to be impacted by laser activation related noise than other noises. Given the short duration (less than 30 seconds) and proposed infrequent operation of the lasers, any startle responses in animals would be short-lived and localized to the area near the activation site. (U.S. Department of the Air Force, 1997b)

Indoor testing would be contained and would not damage vegetation or wildlife in any biome. During outdoor testing, laser beams could either be directed upwards toward air targets or horizontally towards ground targets. If the beam were directed at an upward angle, vegetation and terrestrial wildlife would not be affected. The probability of the laser beam striking a bird is very low. If the beam is directed horizontally toward ground targets, it could pose a fire hazard to vegetation or cause skin or eye damage to wildlife. Precautions would be taken to prevent harm to vegetation and wildlife.

When the light energy of the laser beam is focused, damage due to thermal heating of the retina or a photochemical change in the retina would most likely occur (in the same way that a magnifying glass can be used to focus light energy from the sun to produce a hot spot). (Swope, 1969, as referenced in U.S. Department of the Air Force, 1990) Damage to the fovea (a small part of the retina that provides acute vision) could result in a severe visual handicap. If the eye were not focused on the laser source, the light energy would not be focused to a point on the retina but would be spread out over a larger area of the

retina and would not be as likely to cause damage. Also, if the eye were pointed somewhere off to the side rather than directly at the source, any damage to the retina would be outside the fovea and would be less likely to produce severe visual handicap. (U.S. Department of the Air Force, 1990)

Ground testing of ABLs would use equipment that would simulate atmospheric conditions at the altitude where the laser would be used. The equipment would operate for a few minutes or less, and would generate noise that could affect wildlife. This noise could cause flushing in birds and temporary abandonment of nesting and other normal activities. These noises may startle animals and cause them to flee the area and abandon normal activities. However, studies indicate that birds and animals generally return to normal activities within a short time following noise disturbances. (Manci, et al., 1988) Specifically, a 1982 study by Stewart found that birds exposed to 115.6 to 145.5 dBA short intensity noise events returned to their nests within 2 to 10 minutes after the disturbance. (Stewart, 1982, as referenced in Manci, et al., 1988) In addition, a 1980 study by Jehl and Cooper used shotgun blasts and explosives to simulate short duration noise events and found that nesting birds returned within 30 seconds of the disturbance. (Jehl, J.R and C.F. Cooper, 1980, as referenced in Manci et al, 1988)

Air Operating Environment

Impacts to biological resources from laser activation from air platforms would result in similar impacts to those discussed above for land-based operations. However, the potentially harmful substances would be released at approximately 12,192 meters (40,000 feet) above the Earth’s surface and therefore, would be less likely to affect human health, wildlife, or vegetation. Emissions would be diluted and dispersed quickly in the atmosphere. Terrestrial biota would not be exposed to significant concentrations of emissions. The laser beam would be pointed upward; and therefore, the test geometry would prevent the possibility of harming terrestrial wildlife directly from contact with the beam. Because the laser is activated in the upper troposphere or above, the potential for the beam striking birds in flight would be low.

A misdirected laser beam would have virtually no potential to impact any moving or stationary individual animal, either on land, in the air, or in the sea. The light energy would be reduced (i.e., less concentrated) and would be less able to cause injury because the beam’s width would increase due to atmospheric refraction as it approached the Earth’s surface. Exposure to the beam would be extremely short due to the rapidity with which the beam would swing past the animal or would be shut off; and therefore, damage would be minimal. (U.S. Department of the Air Force, 1990)

Geology and Soils

Land Operating Environment

Only small amounts of emissions from the operation of the COIL on the ground would be released and would not be expected to affect geology and soils in any biome. Ground testing equipment would receive the laser emissions and scrub them using a vacuum device before releasing them into the atmosphere. Use of the vacuum system would reduce the amount of emissions that could affect geology and soils.

Under rainy or humid conditions, a small amount of chlorine produced from the operation of the COIL would be deposited on the soil as hydrochloric acid, which could result in a temporary increase in soil acidity that might have a short-term effect on vegetation and soil-dwelling microorganisms. The intensity of the acidic effect is a function of the amount of limestone (calcium carbonate) in the soils.

Soils that are strongly leached (removed of nutrients, including calcium) and therefore, acidic could be adversely affected by the addition of hydrochloric acid which could further increase soil acidity. This could occur in the Arctic Tundra, Sub-Arctic Taiga, Savanna, Mountain and parts of the Deciduous Forest, and Tropical Biomes.

Soils with large amounts of calcium carbonate have nearly unlimited buffering capacities and rarely show effects of acidification. (EPA, 2003g) This would be true for soils in the Grasslands, and parts of the Deciduous Forest including Florida and islands in the Pacific and Atlantic Ocean that are limestone-based. However, many soils common throughout the Deciduous Forest Biome lack calcium carbonate due to the warm, humid climate that leads to rapid weathering and subsequent leaching of minerals in soils, including calcium and therefore might be subject to impacts from increased soil acidity.

The Chaparral and Desert Biomes would be unlikely to produce hydrochloric acid as a result of laser activation and therefore soils in these biomes would not be subject to acid deposition from this source.

Accidental releases of spent laser chemicals would be contained in accordance with site-specific spill plans that minimize impacts on geology and soils. In the case of an accidental fire, liquid and solid laser chemicals would either be consumed or contained. Chemicals consumed by the fire would be released as gases and would not impact geology or soils. Remaining laser chemicals would be contained by spill control measures and would be removed and disposed in accordance with standard procedures.

Air Operating Environment

Activation of lasers from an air platform would generally occur at approximately 12,192 meters (40,000 feet). Emissions would occur above the mixing height and might occur above the troposphere. Gaseous emissions occurring at this altitude would be dispersed and diluted in the atmosphere and would not reach the ground surface. Therefore, there would be no impact to geology and soils.

Sea Operating Environment

Laser activation on sea platforms would result in similar impacts to those discussed for land platforms. The small quantities of substances released would be dispersed by atmospheric winds or the motion of the ocean currents and waves without affecting geology and soils on the ocean floor beneath the sea operating environment.

Hazardous Materials and Hazardous Wastes

Land and Sea Operating Environments

COIL chemicals include chlorine (Cl_2), iodine, and hydrogen peroxide. Effluents from the operation of the HEL are managed by use of chemical scrubbers and chemical reactions that produce non-toxic by-products. The volume of waste would depend on site-specific activities. The use and disposal of hazardous materials would be incorporated into hazardous materials and hazardous waste management documents. Hazardous materials would be stored in a centralized location and Material Safety Data Sheets would be posted at all locations where hazardous materials are stored or used. All waste would be collected and segregated as nonhazardous, hazardous, and possibly special wastes for proper disposal in accordance with Federal, state, local, and DoD requirements. Personnel would follow safety procedures to prevent exposure. All hazardous materials used and hazardous waste generated would be handled in accordance with a Hazardous Waste and Hazardous Materials Standard Operating Procedure Manual as well as applicable legal requirements. (U.S. Army Space and Missile Defense Command, 2002d) Accidental releases of hazardous materials would be contained in accordance with a site-specific spill plan.

Laser activation activities would produce the same hazardous materials and hazardous waste impacts in all of the biomes considered in this PEIS. As discussed above for impacts to geology and soils, ground testing of lasers intended for use from air operating environments would use vacuum and scrubber devices to simulate atmospheric conditions at the proposed operating altitude. Scrubbing would generate hazardous wastewater that would be contaminated and corrosive. This contaminated water would be treated and disposed in accordance with applicable regulations.

Spent laser chemicals would be neutralized and reused elsewhere in the chemical mixing facility or disposed of as waste product. This waste would be handled, treated, and disposed in accordance with standard procedures, preventing the release of contamination. In the case of an accidental fire, liquid and solid laser chemicals would either be consumed or contained. Chemicals consumed by the fire would be released as gases and would not become hazardous waste. Remaining laser chemicals would be contained by spill prevention, countermeasure, and control plans, and would be removed and disposed in accordance with applicable regulations and standard operating procedures. Laser chemical and chemical waste storage areas would operate in accordance with appropriate regulations to minimize impacts from potential spills and/or leaks.

Air Operating Environment

Emissions from laser activation from air platforms would be vented to the atmosphere while the platform is at operational altitude. Thus, emissions would not reach the Earth, and would not require treatment as hazardous waste.

In the event of an accident on the runway causing rupture of fuel bladders on the B-747, the impact on geology, soil, or water resources from the jet fuels and firefighting materials would be similar to the impact from other aircraft accidents. The liquid and solid laser fuels released in an accident on the runway would be consumed by fire or contained, and the gaseous laser fuels would either burn or vent to the atmosphere where they would not impact geology, soils, or water quality.

Health and Safety

Land and Sea Operating Environments

Laser activation activities would produce the same impacts on health and safety in all of the biomes considered in this PEIS. A Material Safety Data Sheet would be made available for each hazardous chemical in use at the facility. Storage specifications for hazardous chemicals would prevent dangerous intermixing of reactive chemicals.

Exhaust emissions from laser activation have the potential to harm human health. A safety zone would be established around the laser during operation to prevent exposure to emissions. The general public and non-operational personnel would not be permitted in the safety zone during operations; and therefore, no impact on health and safety would be expected from exhaust emissions.

Before activation activities are conducted, components would be reviewed for hazards. Personnel would be trained to handle laser chemicals and operate the laser. During ground testing of lasers, the beam would be contained in a beam containment system at

all times. During sea-based operations, a laser hazard zone would be established to prevent non-essential personnel or bystanders from crossing the direct or reflected beam path of the laser.

An accidental release of laser chemicals and chemicals used to support laser operation would have the potential to affect health and safety of workers in the vicinity of the release. The primary scenarios for an accidental release involve the transfer of the reactants from the loading truck to the ground storage tanks, transfer from the storage tank to the test apparatus, a catastrophic storage container failure, and a massive release of hazardous chemicals resulting either from the slow combustion or the detonation of compounds where reactants are stored. (BMDO, 2001) Spill control procedures would be followed on military installations, and emergency response personnel would be trained to respond to such emergencies.

Laser beams can cause serious health problems if they contact the skin or eyes. Hazard distances would be determined for each laser depending on the hazardous and adverse biological impacts it has on the eye or skin. A spherical exclusion area would be established around the laser during operation. While the intended beam direction is the most likely hazard area, the spherical shape of the exclusion area would account for laser scatter, the intensity of which can be as strong as or weaker than the original beam. HELs are dangerous at the source of the laser beam, and they become more dangerous around the focus point, where the beam has the smallest cross-sectional area. The strength of a laser beam is attenuated and scattered as it moves through the atmosphere. Lower energy lasers (such as those used in laser sensing and tracking systems) may not be dangerous at the source of the beam, but may become dangerous around the focus point.

During ground testing activities, the laser beam would be directed away from population centers. Range areas would be used during ground testing and public access to these areas would be restricted. Laser targets would be designed to keep any spectral hazard on the range or to exit at a safe altitude. Hazard zones would be blocked off to prevent exposure to personnel. Target backstops would be used in case the laser misses the target.

Air Operating Environment

The accidental release of laser chemicals onboard an aircraft during flight would be highly unlikely. The accidental release of chemicals inside the aircraft during flight would not endanger the flight crew because the aircraft would include a pressure bulkhead that separates the chemical storage areas from the flight crew area. This pressurized bulkhead would ensure that any laser emissions would not penetrate the inhabited portion of the aircraft. Chemicals could also be jettisoned to minimize the amount released inside the aircraft.

Flight test activities would be configured so that reflected lasers would be contained within range boundaries. Exposure to a reflected laser beam would likely be very short, less than 0.01 seconds in duration and would not impact health and safety. (U.S. Air Force, 1997a, as referenced in MDA, 2003a)

Noise

Land and Sea Operating Environments

Laser activation activities would produce the same noise levels in all of the biomes considered in this PEIS. The potential for impact would depend on the specific operating location. Operation of equipment to support tests of lasers on land and sea operating environments would last for less than five minutes for each test. (U.S. Department of the Air Force, 1997b) The public and on-site personnel would be excluded from the area where the noise from this equipment would be detrimental. The size of this exclusion area would be determined using OSHA limit for noise exposure.

High noise levels between 110 and 134 dBA are associated with the pressure recovery system during activation of the laser. All personnel who could be affected would be evacuated from the area for their protection or required to wear appropriate hearing protection.

Air Operating Environment

Activation of the laser on an air platform would take place at an altitude of approximately 12,192 meters (40,000 feet), and noise resulting from this activation would not affect ground level noise.

Transportation

Land and Sea Operating Environments

Air traffic is the transportation mode that might be affected by the activation of lasers. The use of lasers from land and sea platforms has the potential to impact the use of airspace if the laser beam were directed upwards.

Air Operating Environment

The use of lasers from air platforms could also impact the use of airspace. The impacts on airspace are discussed above. These impacts would be the same in all of the biomes considered in this PEIS.

Water Resources

Land Operating Environment

Chlorine released by the operation of the COIL would react with water vapor in the atmosphere to produce hydrochloric acid. Hydrochloric acid absorbed by surface waters would cause a temporary pH change such that any alteration of the water's pH would be almost imperceptible. (U.S. Department of the Air Force, 1997b)

In areas where precipitation is heavy, catchment basins are small, and stream gradients are steep hydrochloric acid would pass quickly out of stream drainages. (FAA, 1996) Ocean waters would not be significantly affected by changes in pH due to sea water's ability to readily neutralize acid.

Usually the chlorine exhaust cloud would be highly dispersed before coming into contact with surface waters and would become dilute hydrochloric acid upon mixing with water. Under rainy or humid conditions, chlorine could be concentrated spatially or locally in nearby ground and surface water sources. This could occur in the Arctic Tundra, Sub-Arctic Taiga, Deciduous Forest, and Mountain Biomes. In addition, hydrochloric acid could be produced in the Sub-Arctic Taiga, Chaparral, Savanna, and Grasslands Biomes when cool and humid conditions exist during laser activation activities. The strong winds in the BOA would support the rapid dispersion of emissions. Given the dry conditions in the Desert Biome it is unlikely that chlorine would be converted to hydrochloric acid. The Tropical Biome is generally humid but the temperatures do not cool enough to convert the chlorine produced as a result of laser activation to hydrochloric acid.

Hydrochloric acid deposition in surface waters may cause temporary increases in water acidity. Once deposited, hydrochloric acid would be diluted and dispersed by the receiving waters. Therefore, hydrochloric acid emissions would have minimal impacts on water pH levels and would not be considered harmful.

Sources of potential ground water contamination are spills of cooling water or stored chemicals and/or leaks from the chemical waste and sludge tanks. Accidental releases of spent laser chemicals would be contained in accordance with site-specific spill plans that minimize impacts on water resources.

In the case of an accidental fire, liquid and solid laser chemicals would either be consumed or contained. Chemicals consumed by the fire would be released as gases and would not impact water resources. Remaining laser chemicals would be contained by spill prevention and control measures, and would be removed and disposed in accordance with standard procedures.

Ground testing of ABLs would use vacuum and scrubbing equipment that would result in hazardous wastewater that would need to be treated and disposed in accordance with applicable regulations.

Air Operating Environment

Activation of lasers from an air platform would occur at an altitude of approximately 12,192 meters (40,000 feet), which is higher than the mixing height. Emissions would be dispersed by wind and diluted in the atmosphere and would not impact surface water resources.

Sea Operating Environment

Impacts from laser activation during sea-based operations would be similar to those described above for land operations. The addition of hydrochloric acid to the ocean from the operation of the COIL would cause a slight increase in acidity of waters in the immediate vicinity of the contact point. However, saltwater tends to readily neutralize acid and the continual movement of waves further disperses and dilutes the chemicals. Therefore, significant acidification would not occur in the ocean.

4.1.1.2 Weapons - Interceptor*s*

As described in Exhibit 4-3, the analysis for interceptors is based upon impacts from prelaunch, launch/flight, and postlaunch activities.

Air Quality

Prelaunch Activities

For pre-fueled liquid propellant boosters and solid propellant boosters, prelaunch activities, such as elevating the booster to the launch angle and attaching fins to the booster, would not significantly impact air quality in any of the biomes considered in this PEIS.

For non-pre-fueled liquid propellant boosters, the prelaunch activity with the greatest potential for air quality impacts is fueling. All fueling procedures would need to be approved by the site where the activity is to occur, and associated emergency response plans would need to be reviewed before beginning fueling activities. Although total oxidizer and fuel vapor emissions would vary depending on the propellant transfer equipment used and how it is assembled, it is anticipated that only very small amounts (approximately 10 grams [0.4 ounces]) of oxidizer vapors would be released to the atmosphere during the oxidizer transfer operation. A negligible amount of fuel vapors

would also be released into the atmosphere during fuel transfers. (U.S. Army Space and Missile Defense Command, 2002c)

Propellant releases, although unlikely, could occur during propellant loading or transfer due to failure of transfer equipment or valves. An analysis conducted for the *Liquid Propellant Targets Environmental Assessment* (2002) assumed a leak over a three-minute period would release up to 17 liters (4.5 gallons) of oxidizer inhibited red fuming nitric acid (IRFNA), hydrogen peroxide, or nitrogen tetroxide, or hydrazine fuel.

Boosters could be shipped to the test range with the kill vehicle attached, or the booster could be shipped separately from the kill vehicle. In either case, the fuel and oxidizer tanks would be installed in the kill vehicle at the test site. If the booster is shipped separately from the kill vehicle, the kill vehicle would be mated to the booster in a missile assembly building. These structures are commonly used for these types of activities, and no impacts to air quality would be expected from the mating and assembly process. (U.S. Army Space and Missile Defense Command, 2003)

Launch/Flight Activities

Launches of pre-fueled liquid propellant boosters would use a solid propellant gas generator as the ignition source. This solid propellant gas generator would have emissions similar to those discussed for solid propellant boosters; however, the quantities involved would be significantly smaller. The primary exhaust products of pre-fueled liquid propellant boosters are water, H_2, N_2, hydrogen fluoride, CO_2, and CO.

Emissions from the launch of pre-fueled liquid propellant boosters would have minimal impact on air quality. (Cortez III Environmental, 1996) The only HAPs produced from launches of these missiles would be from the solid propellant gas generator, which would produce approximately 0.05 kilograms (0.10 pounds) of hydrochloric acid per launch, which is much less than the Clean Air Act regulatory reporting requirement of nine metric tons (10 tons) per year. (U.S. Department of the Air Force, 1997b)

Launches of non-pre-fueled liquid propellant boosters would be started by using triethylamine and dimethylaniline as an initiator fuel. The initiator fuel would have emissions similar to those discussed for the primary exhaust products for liquid propellants. The primary exhaust products of non-pre-fueled liquid propellant boosters are CO, CO_2, H_2, N_2, and water. Emissions from the launch of non-pre-fueled liquid propellant boosters would have minimal impact on air quality.

The primary exhaust products of solid propellant boosters are HCl, CO, NO_X, and aluminum oxide (Al_2O_3). HCl and CO emissions are gases and Al_2O_3 is emitted as particulate. CO and NO_X emissions are further oxidized to CO_2 and NO_2 due to the high temperatures experienced during launch; however, the quantities released from a single

test event are not expected to contribute to localized accumulation of greenhouse gases. Gaseous HCl produced by launches of solid propellant boosters combines with water in the atmosphere to create hydrochloric acid aerosol, which may contribute to the formation of acid rain. This is a particular concern in high precipitation areas or humid biomes where moisture in the air could aid the conversion of HCl to hydrochloric acid. Several biomes including Arctic Tundra, Sub-Arctic Taiga, Deciduous Forest, and Mountain Biomes are considered humid. In addition, acid precipitation could be produced in the Sub-Arctic Taiga, Chaparral, and Grasslands Biomes when cool and humid conditions exist during launch activities.

As the booster proceeds through the layers of the atmosphere the impact of emissions from launch/flight activities varies depending on the propellant system used. One emission of concern produced by some liquid propellant boosters is CO, which can cause radiative heating and minor chemical reactions when emitted in the stratosphere.

Launch/flight activities can contribute to global warming through the emission of greenhouse gases. These emissions could include water vapor and CO_2. However, launch/flight activities would not contribute significantly to the total emissions of these gases, and so would not have a significant effect.

Within the stratosphere, ozone depletion is a primary concern. Ozone in the stratosphere provides a protective layer shielding the Earth from ultraviolet radiation and subsequent harmful effects. Ozone may be depleted through complex reactions with chlorine, Al_2O_3, and NO_X.

Solid propellant boosters emit HCl through high temperature afterburning reactions in the exhaust plume, which could partially be converted to atomic chlorine and molecular chlorine (Cl and Cl_2). These active forms of chlorine can contribute to localized ozone depletion in the wake of the booster. The USAF atmospheric interceptor technology (*ait)* vehicle may be representative of solid propellant boosters that would be used as part of the BMDS. The *ait* would spend approximately 25 seconds in the stratosphere at an altitude between 15 and 40 kilometers (9 and 25 miles). The first stage of the *ait* would deposit approximately 181 kilograms (400 pounds) of HCl and approximately 249 kilograms (550 pounds) of combined Cl and Cl_2 between an altitude of 15 kilometers (9 miles) and 34.6 kilometers (21.5 miles). This represents less than 14 kilograms (30 pounds) of active chlorine being distributed per kilometer of altitude traveled by the test vehicle. The second stage of the *ait* would contribute a total of approximately 3 kilograms (6 pounds) of HCl, Cl, and Cl_2 between ignition and 40 kilometers (25 miles) altitude. It is estimated that less than one pound per kilometer of altitude of the active forms of chlorine would be emitted by the second stage. Due to the large air volume over which these emissions would be spread, and because of rapid dispersion by stratospheric winds, the active chlorine from launches would not contribute to significant localized ozone depletion.

The emission of Al_2O_3 has been the subject of study with respect to ozone depletion. Al_2O_3 is emitted as solid particulates that may serve as sites for atmospheric chemical reactions. The studies (Molina, 1996, as referenced in U.S. Department of the Air Force, 1997a) indicate that Al_2O_3 can activate chlorine. The exact magnitude of ozone depletion that can result from a build-up of Al_2O_3 over time has not yet been determined quantitatively, but appears to be insignificant based on existing analysis.

Exhaust from the first stage of the USAF *ait* vehicle is approximately 27 percent by weight Al_2O_3, and the second stage exhaust is 35.4 percent Al_2O_3 by weight. The total amount of Al_2O_3 deposited between an altitude of 15 and 40 kilometers (9 and 25 miles) by each USAF *ait* flight is approximately 535 kilograms (1,180 pounds) from the first stage and 38 kilograms (83 pounds) from the second stage. The Al_2O_3 emitted during *ait* flight is in the form of smooth particles with sizes varying in diameter from less than one micron to ten microns. (Beiting, 1997, as referenced in U.S. Department of the Air Force, 1997a) Depending on the altitude where these particles are emitted, they may diffuse out of the stratosphere over a period of weeks to a few years. The particles would participate in reactions that may cause ozone depletion during the time that they stay in the stratosphere. (Molina, 1996 and Jackman, 1996, as referenced in U.S. Department of the Air Force, 1997a) The Al_2O_3 solid particles would have the potential to contribute to ozone-depleting reactions while in the stratosphere but because of the large air volume in the stratosphere and rapid mixing, they would not cause significant localized effects on stratospheric ozone depletion.

NO_X is produced during high temperature reactions known as afterburning in the exhaust plume of solid propellant boosters. As the temperature of the exhaust decreases with increasing altitude, less NO_X is formed. For the USAF *ait*, the first stage afterburning production of NO_X is nearly stopped before the vehicle reaches the stratosphere. The total NO_X deposited in the stratosphere is approximately two kilograms (four pounds) from the USAF *ait* first stage and less than 0.5 kilograms (one pound) from the second stage. Stratospheric winds would disperse these quantities rapidly; therefore, no significant effect on ozone depletion would be expected from these emissions. (Molina, 1996, as referenced in U.S. Department of the Air Force, 1997a)

Land and Sea Operating Environments. Because the booster is moving away from the point of launch, only a small portion of the launch exhaust would be emitted near the launch area. In general, biomes with moderate to high winds experience less concentration of air emissions because the winds tend to disperse the ground level emissions. These biomes may include: Deciduous Forest, Chaparral, Desert Biomes, and the BOA. Other biomes including the Arctic Tundra, Sub-Arctic Taiga, Grasslands, Tropical, Mountain, and Savanna may experience higher localized concentrations of air emissions although this would depend on the site-specific conditions.

Launch activities would not be expected to bring any new stationary emission sources to the launch area; therefore, new permits or changes to existing air permits would not be required. If new stationary emission sources were introduced into the region, it is possible that additional permits or changes to existing air quality permits would be required.

Kill vehicles could use either solid or liquid propellants. The liquid propellants likely to be used on the kill vehicle are hypergolic propellants, which would be used in small quantities. Because the launch/flight of kill vehicles is not initiated until the vehicle is high above the Earth's surface, emissions released from the kill vehicle would occur above the troposphere (10 kilometers [6.2 miles]) and therefore, would not impact ground-level air quality.

Air Operating Environment. Launches of pre-fueled and non-pre-fueled liquid and solid propellant boosters from air-based platforms would have less impact on ground-level air quality than launches from land or sea platforms because these launches would produce air emissions at a higher altitude. Using this type of operating environment, the rocket motor would be ignited at an altitude from 1.5 to 6 kilometers (0.93 to 3.7 miles). At this altitude, the booster would be ignited in the troposphere (extending to 10 kilometers [6.2 miles] above the surface of the Earth). Pollutants above the troposphere (and therefore, above the mixing layer) do not significantly impact ground-level air quality. The mixing layer allows for vertical "stirring" of air masses, which aids in the dilution of pollutants before they are slowly transported to ground level.

Postlaunch Activities

The impacts of postlaunch activities have been separated into two discussions below – one for air quality impacts when launch debris or residual propellants hit land and the other when these fall into water.

Launch Debris Hitting Land. The amount of residual propellant in the booster when it hits the ground would depend on several factors including how much propellant was in the booster at launch and how far the booster traveled during the mission. The amount of residual IRFNA in a pre-fueled liquid propellant booster could vary from 12 to 343 kilograms (26.5 to 756 pounds) and the amount of residual unsymmetrical dimethyl hydrazine could vary from 14 to 123 kilograms (31 to 271 pounds). A non-pre-fueled liquid propellant booster could impact the ground with approximately 265 liters (70 gallons) of fuel and approximately 473 liters (125 gallons) of oxidizer remaining. The residual propellants could burn upon impact, or one or both propellants could be released to the atmosphere without burning. (Cortez III Environmental, 1996)

If the propellants burn upon impact, short-term impacts to air quality would occur. The ground-based booster impact areas would be isolated from inhabited areas and would be

evacuated prior to a launch; therefore, any exceedances of the NAAQS or exceedances of health-based criteria would not endanger the public. The remote location of the impact area would allow time and distance sufficient to disperse fumes to a non-hazardous level. It is not anticipated that combustion of the propellant(s) would result in air quality impacts beyond the immediate impact site.

If the residual propellants were released to the atmosphere without burning, the IRFNA is likely to be volatilized as NO_X and nitric acid. Observations of launches of pre-fueled liquid propellant boosters at WSMR indicate that a brown cloud has been observed immediately after impact. (Wilson, 1999, as referenced in Cortez III Environmental, 1996) This cloud is likely produced by IRFNA converting to NO_X, which can induce severe irritation to the eyes, skin, and mucous membranes and can lead to suffocation. Unsymmetrical dimethyl hydrazine is a known carcinogen that can react with oxygen and release toxic fumes of NO_X if released to the air without combusting. These releases have been studied to dissipate below hazardous levels within 24 hours and to be undetectable after a period of six months. (Wilson, 1991, as referenced in Cortez III Environmental, 1996) Hydrogen peroxide and hydrocarbons would dissipate when exposed to air. Nitrogen tetroxide if released to the air without combusting would be converted to gaseous form.

Residual propellant from solid propellant boosters would likely continue to burn until expended if encased; however, if released from the motor casing, it is possible that solid propellant would not burn completely. This combustion would have a minor impact on air quality. There is a possibility that the burning solid propellant if encased could start a fire on the ground. The resulting fire could impact air quality in the area immediately surrounding the impact area.

During a mission involving a successful intercept, the kill vehicle would be destroyed and small pieces of debris would impact the Earth’s surface. The small pieces of debris may temporarily serve as sites for chemical reactions in the Earth’s atmosphere until the debris reaches the ground. However, the impacts to air quality would be minimal.

If the propellants in the kill vehicle were released to the atmosphere in an impact, they would either burn up, or one or both propellants could be released to the atmosphere and evaporate. Impacts from either scenario would be similar to those discussed above for propellants released from liquid propellant boosters.

Launch Debris Hitting Water. The impacts to air quality from postlaunch activities resulting in boosters and kill vehicles hitting the ocean would be similar to, but less than those impacts discussed above for boosters and kill vehicles hitting land because the residual liquid propellants would be released into the ocean rather than the air. Impacts to water quality from a direct release to water are described in the hazardous waste

section. Solid propellant, if still in the casing, might continue to burn for some time even under water. However, this would create minimal impacts to air quality.

Airspace

Prelaunch Activities

There would be no impact on airspace from prelaunch activities, including, fueling, evacuations and clearances, and road closures, because these activities do not physically interfere with navigable airspace or affect airspace scheduling.

Launch/Flight Activities

Close coordination with the appropriate FAA ARTCC and relevant military installations with responsibility for airspace management would minimize the potential for any adverse impacts on airspace use and scheduling for launches from all operating environments in all of the biomes considered in this PEIS. Launches of boosters and kill vehicles would require coordination with current aeronautics and space activities within the airspace associated with launch sites. Launch, flight, and impact of boosters and kill vehicles would occur in designated areas of cleared airspace.

Land Operating Environment. Although launches of interceptors might require closure of some airspace and would, therefore, impact the amount of available airspace, this type of activity is considered routine at many military installations and would not constitute a significant impact. Aircraft transiting the area would be notified of any necessary rerouting requirements before departing their originating airport and would thus be able to take on any additional fuel before takeoff to avoid the affected area. Launches would be scheduled such that they would not affect airborne activities outside the airspace complex(es) where they are to occur, and would not interfere with any low- or high-altitude en route airways or jet routes use by civilian or private airports in the vicinity of the launch site.

In addition, before conducting an operation that is potentially hazardous to non-participating aircraft, Notices to Airmen (NOTAMs) would be established in accordance with range safety procedures. To satisfy airspace safety requirements, the responsible official would obtain approval from the FAA, prior to conducting the launch. Provisions also would be made for surveillance of the affected airspace by radar and patrol aircraft prior to booster launch. Safety regulations dictate that hazardous operations are suspended when any non-participating aircraft enters any part of the hazard area. Operations would resume when the non-participating entrant has left the area or a thorough check of the suspected area has been performed. For these reasons, no adverse impacts to airspace are expected from ground launches.

Air Operating Environment. Within minutes after launch, the booster would be propelled to an altitude of several hundred thousand feet, well above the typical altitudes used by commercial aircraft. The launches, flight trajectory, and ground impacts would occur at sufficient distance and altitude to be virtually unnoticed by local, non-military flying activities. Other impacts to airspace from launches of boosters from air operating environments would be as described for launches from land operating environments.

Sea Operating Environment. Potential impacts to airspace from launches of boosters from sea platforms would be minimized by coordination between airspace complexes. Procedures would be similar to those for launches from land and air operating environments. If the sea operating environment were positioned in the BOA, potential impacts would be further minimized because airspace over the BOA is not heavily used.

Establishing restricted areas would marginally reduce the amount of navigable airspace in the BOA, but because the airspace is not heavily used, the impacts to controlled and uncontrolled airspace would be minimal. If possible, the sea environment would be positioned to avoid the en route airways and jet routes that cross the BOA. Therefore, no significant impacts to the over-water airways and jet routes would be expected from any type of missile launched from a sea operating environment.

Postlaunch Activities

Impacts of postlaunch activities on airspace are discussed below addressing postlaunch debris recovery on land and in water.

Launch Debris on Land. If necessary, helicopter retrieval of debris, from boosters or kill vehicles deposited on land would be within the boundaries of the designated impact area and therefore, within the airspace complex. Debris retrieval would have no impact on navigable airspace or airborne activities outside the restricted airspace complex.

Launch Debris in Water. If debris from boosters or kill vehicles falls into water, MDA would not likely recover the debris. Therefore, helicopters and other equipment would not be used, and no impacts to airspace would be expected. If it were necessary to recover debris from water for a specific test, the impacts of debris retrieval would be analyzed as appropriate.

Biological Resources

Prelaunch Activities

There would be no impacts to biological resources from prelaunch activities for pre-fueled and solid propellant boosters and kill vehicles. For non-pre-fueled liquid propellant boosters, no more than a few grams of propellant would be released during

normal fueling operations and appropriate responses to leaks and releases would be implemented to minimize the hazard to biological resources. All fueling would be conducted using impermeable barriers appropriate for this type of activity, which would minimize the potential for a spill to impact biological resources.

Launch/Flight Activities

The presence of launch-related personnel prior to launch, noise associated with launch, and launch emissions all have the potential to impact biological resources during launch.

Informal observation at several launch facilities indicates that the increased presence of personnel immediately before a launch tends to cause birds and other mobile species of wildlife to temporarily leave the area prior to the launch. This would effectively reduce the effects of sound, launch emissions, and heat on these animals. However, personnel associated with the launch would comply with USFWS, other regulatory agency, and relevant site-specific procedures to protect biological resources including species of special concern.

The effects of noise on wildlife can be categorized as either auditory or non-auditory. Auditory effects would consist of direct physical changes, such as eardrum rupture or temporary threshold shift (temporary hearing loss). Non-auditory effects could include stress, behavioral changes, and interference with mating or foraging success. The effects of noise on wildlife vary from serious to no effect in different species and situations. Animals can also be sensitive to noises in some situations and insensitive to the same noises in other situations. (Larkin, 1996) Behavioral responses to noise also vary from startling to retreat from favorable habitat.

Launches would be relatively infrequent events. Disturbance to wildlife would be brief and would not be expected to have a lasting impact nor a measurable negative effect on migratory bird populations. Wildlife would resume feeding and other normal behavior patterns after a launch is completed. Specifically, a 1982 study by Stewart found that birds exposed to 115.6 to 145.5 dBA short intensity noise events returned to their nests within 2 to 10 minutes after the disturbance. (Stewart, 1982, as referenced in Manci, et al., 1988) In addition, a 1980 study by Jehl and Cooper used shotgun blasts and explosives to simulate short duration noise events and found that nesting birds returned within 30 seconds of the disturbance. (Jehl, J.R and C.F. Cooper, 1980, as referenced in Manci et al, 1988) Wildlife driven from preferred feeding areas by aircraft or explosions usually return soon after the disturbance stops, as long as the disturbance is not severe or repeated. (FAA, 1996) Foraging birds would be subjected to increased energy demands if flushed by the noise, but this should be a short-term, minimal effect.

Video camera observations of a wood stork colony located 0.8 kilometer (0.5 mile) south of the Space Shuttle launch pad at Kennedy Space Center showed the birds flew south

away from the noise source and started returning within two minutes, with a majority of individuals returning in six minutes. (NASA, 1997, as referenced in U.S. Army Space and Missile Defense Command, 2002c) This rookery continues to be used successfully, even though it has received peak noise levels of up to 138 dB. (American Institute of Aeronautics and Astronautics, 1993, as referenced in U.S. Army Space and Missile Defense Command, 2002c) Birds roosting within 250 meters (820 feet) of Titan launch complexes at Cape Canaveral Air Force Station have shown no mortality or reduction in habitat use.

Fixed wing aircraft and helicopters are often used for routine flights around the Arctic Tundra Biome. These aircraft noises have been shown to produce sounds that are disturbing to seabirds. (Fjeld et al., as referenced in Chardine and Mendenhall, 2003) Breeding murres and eiders appear to be sensitive to this type of disturbance. Murres do not build nests but rather incubate their eggs on their feet; therefore, overflight noises may produce panic flights, leading to egg loss.

During breeding and nesting periods birds may be less likely to flush from their nests for long periods of time. Monitoring studies of birds during the breeding season indicate that adults respond to Space Shuttle noise by flying away from the nest, but they return within two to four minutes.

Noise associated with launches may disrupt critical nesting and migratory points for birds in the Deciduous Forest and Chaparral Biomes, which are common migration corridors for many species. Efforts at reducing noise interference are already underway to protect the endangered Red-Cockaded Woodpecker in the Southeast U.S., where it is estimated that nearly a quarter of the remaining Red-Cockaded Woodpecker population resides on 16 military installations. (Delaney et al., 2002) Birds located in other biomes may also be impacted by launch activities and the extent of impact would be determined based on site-specific considerations.

Noise level thresholds for impact to marine life in general and marine mammals in particular, are currently the subjects of scientific studies. Because different species of marine mammals have varying sensitivities to different sound frequencies, and the species may be found at different locations and depths in the ocean, it is difficult to generalize sound impacts to marine mammals from booster launches. Should consensus emerge from scientific analyses about the effects of noise on underwater marine mammals, it would be possible to predict the consequences of particular sonic boom contours on marine mammals in the area.

According to analysis provided in the U.S. Navy’s *Point Mugu Sea Range Environmental Impact Statement (EIS)/Overseas EIS* (2002), brief transient sounds such as sonic booms are unlikely to result in significant adverse effects to pinnipeds or whales in the water. Pinnipeds seem tolerant of noise pulses from sonic booms, although reactions may occur.

Temporary displacement, less than one or two days, is considered a less than significant impact. Baleen whales (humpback, gray, and bowhead) have often been observed behaving normally in the presence of loud noises, such as distant explosions and seismic vessels. Most gray and bowhead whales show some avoidance of areas where these noises have pressures exceeding 170 dB. (U.S. Department of the Navy, 2002, as referenced in U.S. Army Space and Missile Defense Command, 2003)

Launch emissions from pre-fueled and non-pre-fueled liquid propellant boosters would have the potential to impact biological resources, but the impact would be minimal. HCl and Al_2O_3 emitted during launches of solid propellant boosters can harm plants and wildlife. Studies indicate that low-level, short-term exposure to HCl, as would be the case in booster launches, would not cause significant damage to vegetation or wildlife. Animals and birds passing through the exhaust plume may be exposed to levels of HCl that would irritate their eyes and respiratory systems. (FAA, 1996, as referenced in U.S. Army Space and Missile Defense Command, 2002a) Al_2O_3 has a very low toxic potential. HCl and Al_2O_3 do not bioaccumulate; and therefore, no effects on the food chain would be expected. Surface water including wetlands could be impacted by the presence of hydrochloric acid, which could lower the pH and have a negative effect on species relying on the wetlands.

Land Operating Environment. Launch activities from land-based operations that take place in previously disturbed areas would not be expected to adversely affect plant species. Launch areas are typically cleared of all vegetation and either covered with a layer of course gravel or left bare. (Cortez III Environmental, 1996) However, fire from a launch mishap at the launch site could impact plant species that may be present. Any fire would be extinguished quickly, where possible, minimizing impacts to vegetation remaining in the area. The risk of fires from launch activities is particularly prevalent in the Chaparral and Tropical Biomes, which are prone to wildfires.

Sea Operating Environment. Pollutants would be present in the exhaust plume from boosters launched from sea platforms that could threaten wildlife near the point of the sea launch. However, these pollutants would be produced in trace quantities and would not have measurable effects on biological resources.

Postlaunch Activities

Impacts of launch debris on biological resources are discussed below on land versus those impacts of debris falling into water.

Launch Debris Hitting Land. The amount of ground disturbed for each booster or kill vehicle impact would be less than 0.2 hectares (0.5 acres). (U.S. Army Space and Missile Defense Command, 2002c) Restoration of impact sites that are currently used for booster or kill vehicle impacts, if deemed necessary, would be conducted on a case-by-case basis

in coordination with the appropriate officials. Because threatened and endangered plant and animal species tend to be widely scattered and occupy small surface areas, the probability of a booster striking an individual of a federally listed, threatened, or endangered species is remote.

New impact areas for boosters or kill vehicles could be created for specific missions. Selection of a new impact area would be coordinated with the appropriate range personnel to avoid or minimize potential harm to protected species. Effects to biological resources from impacts on a new area would be similar to those described above for impacts on existing areas.

Recovery of booster and kill vehicle debris, if required, would be conducted in accordance with the launch site's existing procedures. These procedures outline steps to be taken to avoid known sensitive areas. Off-road vehicle recovery operations would be used only if necessary and would be coordinated with the appropriate responsible officials. Recovery by vehicle would be limited to the minimum number of vehicles necessary to complete the operation. If necessary, light-lift helicopters could be used to recover debris in rough terrain. Aircraft, particularly helicopters, are loud and produce sounds that might disturb wildlife. Low altitude helicopter flights, which are known to cause panicky reactions in some wildlife species, would be intermittent, would involve gradual descents when necessary, and would then return to altitudes that would avoid further startling effects.

In the unlikely event of flight termination or catastrophic missile failure, the impact of debris on land areas may damage vegetation and wildlife. In the case of flight termination or missile failure, debris and residual propellant could result in a fire that could damage vegetation and wildlife. However, impact areas would generally be cleared of vegetation, minimizing the potential for impact to biological resources due to fires. Hazardous debris, if any, would be recovered as quickly as possible.

Launch Debris Hitting Water. Debris falling into water has the potential to cause non-acoustic effects to biological resources. These effects include physical impact by falling debris, entanglement in debris, and contact with or ingestion of debris or propellants.

Boosters hitting the ocean surface would impart a considerable amount of kinetic energy to the ocean water upon impact. Interceptors would hit the water with speeds of 91 to 914 meters (300 to 3,000 feet) per second. The shock wave from their impact with the water would be similar to that produced by explosives. Depending on the water depth, strong waves from the impact may detach kelp strands from the sea floor. During successful missions, boosters would impact in the deep open ocean waters. At close ranges, injuries to marine mammal internal organs and tissues would likely result.

However, the density of marine species including marine mammals generally decreases, and the corresponding probability of impact decreases, as the distance from the shore increases. Injury to any marine mammal by direct impact or shock wave impact would be extremely remote (less than 0.0006 (6 in 10,000) marine mammals exposed per year). (U.S. Department of the Navy, 2002b)

Impacts to marine biological resources from releases of residual propellants from liquid propellant boosters would not be significant. The natural buffering capacity of sea water and the strong ocean currents would neutralize the reaction to any release of the liquid propellants. Impacts to water quality from a direct release to water are described in the hazardous waste section.

The parts of solid rocket motor propellant expelled from a destroyed or exploded rocket motor that fall into the ocean would most likely sink to the ocean floor at depths of thousands of meters. At such depths, the propellant parts would be located away from feeding marine mammals. (U.S. Department of the Navy, 1998 as referenced in U.S. Army Space and Missile Defense Command, 2003) Therefore, marine animals would not be impacted from ingesting the solid propellant.

Geology and Soils

Prelaunch Activities

There would be no impacts to geology and soils from prelaunch activities for pre-fueled liquid and solid propellant boosters. Fueling of non-pre-fueled liquid propellant boosters would be conducted using appropriate impermeable barriers. (U.S. Army Space and Missile Defense Command, 2002c) Adherence to these procedures would minimize the potential for spills and any impacts to soils.

Launch/Flight Activities

Impacts to geology and soils are discussed separately below for land, sea and air operating environments.

Land Operating Environment. Potential geology and soils impacts from ground launches would be minor. Emissions that occur above the mixing height or above the troposphere would not affect geology and soils.

Soils that are strongly leached (removed of nutrients, including calcium) and are therefore acidic could be adversely affected by the addition of hydrochloric acid produced when HCl interacts with water in humid biomes further increasing soil acidity. This could occur in the Arctic Tundra, Sub-Arctic Taiga, Savanna, Mountain and parts of the Deciduous Forest, and Tropical Biomes.

The intensity of the acidic effect is a function of the amount of calcium carbonate in the soils. Calcium carbonate in some soils including those in the Grasslands and Deciduous Forest and some limestone rich portions of the Tropical Biome have nearly unlimited buffering capacities and would likely prevent emissions produced from solid boosters from affecting geology and soils. (EPA, 2003g) Therefore, no significant impacts to geology and soils would be expected.

The Chaparral and Desert Biomes are unlikely to produce hydrochloric acid as a result of launches of solid propellant boosters and therefore soils in these biomes are unlikely to be affected by increased acid deposition. Although overall impacts to geology and soils from launch activities are expected to be minor, in areas where launches have not previously occurred, such as the U.S. Mountain Biome, the exhaust ground cloud could impact areas not previously disturbed by launch activities. The specific impacts to these areas would need to be analyzed as appropriate.

Air Operating Environment. Impacts to geology and soils from air-based launches would be minor because ignition of the booster would occur several thousand feet above ground level. Emissions from air launches of boosters would have a smaller effect on geology and soil resources than land launches because the emissions would be at a greater altitude and would, therefore, be subject to greater dispersion and dilution prior to reaching the ground.

Sea Operating Environment. No impacts to geology and soils would be expected from launches from sea-based platforms due to the depth of the ocean in areas from which sea launches would operate.

Postlaunch Activities

Impacts to geology and soils from launch debris hitting land versus falling into water are discussed separately below.

Launch Debris Hitting Land. The debris from boosters and kill vehicles could physically impact the ground surface and overlying soils, but there would be no impact expected on geologic resources. Land surface damage from debris would be variable and determined by impact energy, soil compressibility, presence of water, and altitude from which the debris fell. (U.S. Army WSMR, 1998) The impact of the debris may result in ground depressions up to six meters (20 feet) deep. The extent of immediate physical disturbance to the soil from debris impact is likely to be less than 0.2 hectares (0.5 acres).

Debris recovery, if required, would be limited to necessary vehicles and off-road access would follow the same entry route, to the extent possible, to complete the recovery operations with minimal disturbance to soils. (U.S. Army WSMR, 1998)

Residual propellants may be released upon booster or kill vehicle impact. If the propellants burn on impact, fire containment activities could also cause minor impacts to the soil. If vegetation were damaged, then wind and water erosion could both increase.

If the residual IRFNA or unsymmetrical dimethyl hydrazine in a pre-fueled liquid propellant booster do not explode or burn at impact, then they would most likely be deposited on the ground. The IRFNA would volatilize into the atmosphere. Hydrazine fuel would slowly dissipate from surface soils within 24 hours. Hydrazine fuels buried in an impact crater created by the debris would dissipate over several months and would not significantly impact geology or soils. (Cortez III Environmental, 1996)

If the residual propellants from non-pre-fueled liquid propellant boosters do not explode or burn at impact, then they would most likely be deposited on the ground. The nitrogen tetroxide oxidizer would volatilize into the atmosphere. Any residual nitric acid would react with alkaline soils resulting in the deposition of nitrates that would act as a fertilizer and would not appreciably affect soils. Hydrogen peroxide oxidizer deposited on the ground would decompose into water and oxygen within several hours. Kerosene or JP-8 fuel deposited on the ground would be absorbed by the soil. Personnel at the debris impact site would follow standard operating procedures to determine whether soil remediation or removal and treatment and disposal actions are required.

Launch Debris Hitting Water. No impacts to geology and soils would be expected from debris falling into the ocean due to the depth of the ocean where debris would impact. Inert pieces of debris would be deposited in the ocean and would consist of aluminum, steel, graphite composite, plastic, ceramic, and rubber. These materials would likely sink to the ocean floor; however, they would be unlikely to impact geology and soils in ocean areas.

Hazardous Materials and Hazardous Waste

Prelaunch Activities

The types of hazardous materials used and waste generated during prelaunch, launch/flight, and postlaunch activities would be similar to those currently used and generated at military installations. Accidental releases of hazardous materials would be contained in accordance with site-specific spill plans. Temporary storage tanks and other facilities for the storage of hazardous materials would be located in protected and controlled areas. Activities would be conducted to comply with site-specific spill prevention, control and countermeasure (SPCC) plans, such as an Oil Discharge Prevention and Contingency Plan and a Storm Water Pollution Prevention Plan (SWPPP). (U.S. Army Space and Missile Defense Command, 2002d) Any spill of a hazardous material or hazardous waste that might occur could be quickly remediated in

accordance with a Storm Water Pollution Prevention Plan and SPCC plan that would be developed for each site.

Should it become necessary to remove the propellants from a pre-fueled liquid propellant booster, the propellant would be drained into empty bulk liquid propellant containers stored at the fueling location. (U.S. Army Space and Missile Defense Command, 2002c) The defueled oxidizer tank would be flushed with deionized water, and the fuel tank would be flushed with ethyl alcohol. The booster would be transported back to the missile assembly building for reuse or returned to an appropriate facility. Emergency response planning would be incorporated into the operations requirements to minimize any impacts due to an unplanned release of hazardous materials. Therefore, no significant impacts would be expected.

Non-pre-fueled liquid propellant boosters could be fueled at the launch location, provided there is sufficient space, or at a fixed, permanent facility. Fuel and oxidizer would be transported separately to the loading location and loaded at different times. Spill containment for the propellant transfer operation could be provided by a temporary containment system that is impervious to each particular fuel and oxidizer. One set of temporary containment barriers would be used for fuel, and a second set would be used for oxidizer. (U.S. Army Space and Missile Defense Command, 2002c) After completion of the transfer operations, the transfer equipment would be flushed to decontaminate it. Flushing the fuel transfer system would generate approximately 208 liters (55 gallons) of ethyl alcohol with approximately 40 grams (1.4 ounces) of fuel in solution. Flushing the oxidizer transfer system with deionized water would generate approximately 4,164 liters (1,100 gallons) of neutralized deionized water and oxidizer rinsate (less then 1 percent) and would result in the release of approximately five grams (0.2 ounces) of nitric oxide to the atmosphere. The material generated from flushing the propellant transfer systems would be handled as hazardous waste and would be disposed via appropriate procedures using permitted disposal facilities. Although propellant quantities and fueling systems have not been defined for all non-pre-fueled liquid propellant boosters, it is anticipated that similar materials would be generated when flushing hydrogen peroxide oxidizer and hydrocarbon fuel. Flushing nitrogen tetroxide oxidizer would involve similar methods and materials generated as IRFNA.

Should it become necessary to remove the propellants from the non-pre-fueled liquid propellant booster, the propellant would be transferred into empty bulk liquid propellant containers stored at the fueling location. (U.S. Army Space and Missile Defense Command, 2002c) The propellant containers would then be transported to the respective propellant storage areas for reuse in the next mission. The defueled oxidizer tank would be flushed with deionized water and the fuel tank would be flushed with ethyl alcohol as described above. The booster would be transported back to the missile assembly building for reuse or returned to an appropriate facility.

The fuel and oxidizer tanks in kill vehicles would be installed at the test site. Spill containment and propellant removal procedures would be similar to those described above for non-pre-fueled liquid propellant boosters.

There would be no impacts from prelaunch activities for solid propellant boosters.

Launch/Flight Activities

Launch activities would produce the same hazardous materials and hazardous waste in all biomes considered in this PEIS. Launches would potentially increase the hazardous waste generated at the launch sites. However, this increase in hazardous waste would not overburden the various facilities' hazardous waste management programs, and only minimal impacts would be anticipated. During a nominal launch there would be no hazardous materials or hazardous waste impacts from the launch/flight of boosters or kill vehicles.

Postlaunch Activities

Impacts from hazardous materials and hazardous waste launch debris are addressed separately below on land versus in water.

Launch Debris on Land. Debris from boosters and kill vehicles and residual propellant would be handled in accordance with the appropriate spill contingency plan for the launch location/debris impact site. These plans establish responsibility, outline personnel duties, and provide resources and guidelines for use in the control, clean up, and response to spills.

Entry to the debris impact site would be restricted to trained hazardous material response personnel until the area is determined to be safe. All debris would be tested to determine if it is hazardous waste. Hazardous waste would be disposed via permitted procedures. For a nominal flight, liquid propellant boosters would contain unburned propellant upon impact within the planned impact area. The amount of propellant remaining in the booster would vary depending on the particular mission objectives (i.e., distance flown and fuel burned).

During nominal flights of solid propellant boosters, most of the solid propellant would be expended. Debris would include structural material and batteries. These materials would be inert and would not have any significant impacts. Flight termination or catastrophic failure of the booster would result in the deposition of structural material and battery debris and any residual propellant. Some of the potentially hazardous material contained in the batteries or propellants would likely be consumed during the termination or failure. It is not expected that the remaining debris would pose a significant impact.

Launch Debris in Water. NASA has conducted evaluations of the effects of missile systems deposited in sea waters. The studies determined that materials would be rapidly diluted, and except for areas in the immediate vicinity of the debris, would not be found at concentrations identified as causing any adverse effects. This applies to debris deposited either as a result of successful or unsuccessful intercepts, or due to in-flight malfunction or flight termination along the flight corridor. Eventually, all hazardous materials falling into the ocean would become diluted and would cease to be of concern. NASA determined that the release of hazardous materials aboard missiles into sea waters would not be significant. (NASA, 1973 as referenced in U.S. Army Space and Missile Defense Command, 2003) Therefore, no significant impacts to the ocean environment would be expected from postlaunch activities involving liquid propellant missiles.

During flight termination or catastrophic missile failure of solid propellant boosters, pieces of unburned propellant could be dispersed over an ocean area of up to several kilometers. Once in the water, ammonium perchlorate could slowly leach out and would be toxic to plants and animals. In freshwater at 20^{o}C (68^{o}F), it is likely to take over a year for the perchlorate contained in solid propellant to leach out into the water. (Lang et al., 2000, as referenced in U.S. Army Space and Missile Defense Command, 2003) Lower water temperatures and more saline waters would likely slow the leaching of perchlorate from the solid propellant into the water. Over this time, the perchlorate would be diluted in the water and would not reach significant concentrations. (U.S. Army Space and Missile Defense Command, 2003)

Health and Safety

Prelaunch Activities

The handling and assembly of booster components are typically accomplished within enclosed buildings. These activities would adhere to applicable laws and regulations including the Range Commanders Council Standard 321-02, which establishes limits for risk to human health and safety. These analyses would take into account installation-specific and test-specific safety tolerances (range hazard areas).

Prelaunch activities for pre-fueled liquid and solid propellant boosters would not have any impact on health and safety. All liquid propellant booster fueling procedures for non-pre-fueled liquid propellant boosters would be approved for the site where the activity is to occur, and associated emergency response plans would need to be reviewed before beginning activities to ensure protection of health and safety. Total oxidizer and fuel vapor emissions would vary depending on the propellant transfer equipment used and how it is assembled. It is anticipated that only very small amounts of oxidizer vapors would be released to the atmosphere during the oxidizer transfer operation. A negligible amount of fuel vapors would also be released into the atmosphere during fuel transfers. Exposure to liquid propellants resulting from fueling activities would be minimal. The

existing condition in several biomes would preclude fueling emissions from impacting health and safety of workers; this would be true in biomes where wind conditions would rapidly disperse emissions. Windy conditions are likely in the Sub-Arctic Tundra Biome.

Analysis conducted using the U.S. Air Force Toxic Corridor Model computer model indicated potential exceedances of health standards as shown in Exhibit 4-9. Actual hazard distances would depend on the propellant, the amount released, meteorological conditions, and emergency response measures taken. Standard operating procedures would be developed and would include personal protection equipment procedures and distances at which it would be safe to establish fueling operations area boundaries. Establishment of and adherence to these procedures would minimize the potential health and safety hazards to personnel in the unlikely event of an unplanned propellant release. The low likelihood of such an occurrence and the implementation of approved emergency response plans would limit the impact of such a release. People located at distances in excess of the exceedance distance would not be exposed to health and safety impacts from prelaunch fueling activities.

Exhibit 4-9. Potential Exceedances Due to Accidental Oxidizer or Fuel Leak to Air During Fueling Activities

Propellant	Health Standard	Standard Limit	Exceedance Distance
IRFNA	OSHA Permissible Exposure Limit (PEL)[a]	2 parts per million (ppm) (5 milligrams per cubic meter (mg/m^3))	34 meters (112 feet)
	National Institute for Occupational Safety and Health (NIOSH) Short Term Exposure Limit (STEL)[b]	4 ppm (10 mg/m^3)	20 meters (66 feet)
	Immediately Dangerous to Life and Health (IDLH)[c]	25 ppm (65.5 mg/m^3)	Not Exceeded
Hydrogen Peroxide	OSHA PEL	1 ppm (1.4 mg/m^3)	212 meters (696 feet)
	NIOSH STEL	1 ppm (1.4 mg/m^3)	212 meters (696 feet)
	IDLH	75 ppm (105 mg/m^3)	14 meters (46 feet)
Nitrogen Tetroxide	American Conference of Governmental Industrial Hygienists (ACGIH) Threshold Limit Value (TLV)[d]	3 ppm (5.4 mg/m^3)	310 meters (1,017 feet)
	ACGIH STEL[b]	5 ppm (9 mg/m^3)	227 meters (746 feet)
	IDLH	75 ppm (135 mg/m^3)	103 meters (336 feet)
Hydrazine	OSHA PEL	1 ppm (1.31 mg/m^3)	117 meters (383 feet)

Exhibit 4-9. Potential Exceedances Due to Accidental Oxidizer or Fuel Leak to Air During Fueling Activities

Propellant	Health Standard	Standard Limit	Exceedance Distance
	ACGIH STEL	0.1 ppm (0.131 mg/m^3)	36 meters (118 feet)
	IDLH	50 ppm (65.5 mg/m^3)	Not Exceeded

Source: Modified from U.S. Army Space and Missile Defense Command, 2002c
Notes:
[a] The OSHA PEL is the level of exposure that must not be exceeded when the exposure is averaged over an 8-hour workday and a 40-hour workweek in the workplace.
[b] The NIOSH STEL (or OSHA STEL or ACGIH STEL) is the level of exposure that must not be exceeded at any time during a workday when the exposure is averaged over 15 minutes.
[c] The IDLH is the level of exposure (not time-weighted) above which it is anticipated a person would suffer life-threatening or irreversible health effects or other injuries that would impair them from escaping the hazardous environment.
[d] The ACGIH TLV is an average value of exposure over the course of an 8-hour work shift.
[e] Exceedance Distance-Average of U.S. Air Force Toxic Corridor model results for 15-minute and 30-minute averaging time and multiple stability classes.

Boosters could arrive at the test range with the kill vehicle attached, or the booster may be shipped separately from the kill vehicle. In either case, the fuel and oxidizer tanks would be installed in the kill vehicle at the test site. If the booster is shipped separately from the kill vehicle, the kill vehicle would be mated to the booster in a missile assembly building at the launch facility. These structures are commonly used for these types of activities and no impacts to health and safety would be expected from the mating and assembly process. (U.S. Army Space and Missile Defense Command, 2003)

Launch/Flight Activities

Launch activities would produce the same impacts on health and safety in all of the biomes considered in this PEIS. Potential impacts to health and safety include exposure to explosives, contact with launch debris, and exposure to noise produced during launch. Because launches would take place on facilities with restricted access, members of the public would not be exposed to these hazards.

Appropriate health and safety standard operating procedures would be developed to protect personnel. Every reasonable precaution would be taken during the planning and execution of a launch to prevent injuries.

A written procedure for all explosive activities is required and must be approved by the appropriate range authorities. Established procedures to prohibit access to restricted areas would be followed. The restricted areas are based upon the probability of potential hazards involved with malfunction during launches and would include

- The impact limit line, which sets the boundary protection line for all non-mission essential personnel;
- The launch caution corridor, an area limited to essential personnel;
- The LHA, an area around the launch point limited to essential personnel in hardened facilities; and
- The stage or booster impact area.

Impact zones for each launch would be delineated based on detailed launch planning and trajectory modeling, which would include analysis and identification of a flight corridor. Flights would be conducted when trajectory modeling verifies that launch-related debris would be contained within predetermined areas, all of which would be located away from inhabited land and populated areas.

Launch-related personnel that would be exposed to noise in excess of applicable standards including OSHA regulation 1910.95 would be required to wear appropriate hearing protection, which would reduce the noise levels to prescribed health and safety levels.

Postlaunch Activities

There is the potential for impact of debris from boosters and kill vehicles at any point along the flight corridor due to missile malfunction and/or termination of a missile flight by the FTS. The resulting debris would follow a ballistic trajectory and would impact in designated impact areas either on land or in the ocean. Because an exact point of termination cannot be determined, the potential effects footprint is determined by considering the limits of debris fallout based on destruction of a test missile at the boundaries of the acceptable flight corridor, along with additional flight time based on the time required to initiate the FTS. The possibility of debris hitting the ground or water outside the designated impact area is remote; and therefore, safety impacts of flight termination would not be significant. Debris modeling and analysis would be conducted for specific proposed activities as appropriate.

Launch Debris on Land. Procedures would be developed to establish appropriate debris recovery procedures, as necessary, and would include personal protective equipment and determination of appropriate recovery zone hazard boundaries. Therefore, no health and safety impacts would be expected from postlaunch activities.

Exhibit 4-10 indicates the results of an analysis using the U.S. Air Force Toxic Corridor Model to determine distances at which various health standards could be exceeded based on the release of residual propellant at the debris impact area. The analysis was conducted for non-pre-fueled liquid propellant boosters assuming 473 liters (125 gallons) of the remaining oxidizer and 265 liters (70 gallons) of the remaining fuel were released

to the atmosphere. People located at distances in excess of the exceedance distance would not experience impacts to health and safety from postlaunch activities.

Exhibit 4-10. Potential Exceedances Due to Accidental Oxidizer or Fuel Leak at the Booster Impact Site

Propellant	Health Standard	Standard Limit	Exceedance Distance
Inhibited Red Fuming Nitric Acid (IRFNA)	OSHA PEL	2 ppm (5 mg/m^3)	213 meters (699 feet)
	NIOSH STEL	4 ppm (10 mg/m^3)	140 meters (458 feet)
	IDLH	25 ppm (65.5 mg/m^3)	50 meters (164 feet)
Hydrogen Peroxide	OSHA PEL	1 ppm (1.4 mg/m^3)	195 meters (639 feet)
	NIOSH STEL	1 ppm (1.4 mg/m^3)	195 meters (639 feet)
	IDLH	75 ppm (105 mg/m^3)	11 meters (36 feet)
Nitrogen Tetroxide	ACGIH TLV	3 ppm (5.4 mg/m^3)	1,074 meters (3,525 feet)
	ACGIH STEL	5 ppm (9 mg/m^3)	740 meters (2,429 feet)
	IDLH	75 ppm (135 mg/m^3)	274 meters (899 feet)
Hydrazine	OSHA PEL	1 ppm (1.31 mg/m^3)	462 meters (1,515 feet)
	ACGIH STEL	0.1 ppm (0.131 mg/m^3)	123 meters (404 feet)
	IDLH	50 ppm (65.5 mg/m^3)	13 meters (44 feet)

Source: Modified from U.S. Army Space and Missile Defense Command, 2002c

Launch Debris in Water. Booster trajectories would be established to preclude potential water impacts in heavily trafficked ocean areas. Notices to Mariners (NOTMARs) would be issued as appropriate to advise mariners of the projected impact area. In the event of a flight termination, the possibility of debris impacting a sea vessel would be remote, and therefore safety impacts of flight termination would not be significant.

During flight termination or catastrophic missile failure of solid propellant boosters, pieces of unburned propellant could be dispersed over an ocean area of up to several kilometers. Once in the water, ammonium perchlorate could slowly leach out. In 1985, perchlorate was detected in wells of California Superfund sites; however, perchlorate contamination was not detected nationwide until 1997. Currently there are no Federal drinking water standards for perchlorate. The EPA has the responsibility to establish national drinking water standards and has issued draft risk assessments of perchlorate. These assessments have been criticized because it has been suggested that the findings are based on flawed scientific studies and that not all available data were considered and incorporated. Because of these controversies, the EPA, DoD, DOE, and NASA asked the National Research Council (NRC) to independently assess the adverse health effects of perchlorate ingestion from clinical, toxicological, and public health perspectives. The NRC was also tasked to review the scientific literature and findings from the EPA's 2002

draft risk assessment, *Perchlorate Environmental Contamination: Toxicological Review and Risk Characterization*.

Although there are no Federal drinking water standards for perchlorate several states have proposed interim guidance levels or goals for perchlorate levels in drinking water. In March 2004, the State of California Office of Environmental Health Hazard Assessment established a public health goal for perchlorate in drinking water of 6 parts per billion. (California Office of Environmental Health Hazard Assessment, 2005) The NRC study considered the health impacts from perchlorate exposure. The results of this study and an overview of additional relevant studies on the impacts of perchlorate on human health and the environment are discussed in Appendix M of this PEIS.

Perchlorate can impact thyroid function because it inhibits the transport of iodide into the thyroid. The NRC study examined short-term studies that found that to negatively impact the thyroid, iodide uptake by the body would need to be reduced by at least 75 percent for months or longer. The NRC reported results of longer term studies that found that to cause hypothyroidism in adults would require them to be given more than 0.40 milligrams per kilogram (mg/kg) of perchlorate (assuming a body weight of 70 kilograms). However, in pregnant women, infants, children, and people with low iodide intake or pre-existing thyroid dysfunction, the dose required to cause hypothyroidism may be lower.

Epidemiologic studies considered by the NRC have examined the relationship between perchlorate exposure and thyroid function and thyroid disease in newborns, children, and adults. The NRC concluded that no studies have investigated the effect of perchlorate exposure in vulnerable groups, such as low birth weight or preterm infants. In addition, these studies have not considered the impacts to the offspring of mothers who were exposed to perchlorate and had a low iodide intake. Finally, adequate studies have not been completed of maternal perchlorate exposure and neurodevelopmental outcomes in infants.

The NRC study considered the applicability of animal toxicology studies to human health and found that although studies in rats provide useful qualitative information on potential adverse effects of perchlorate exposure, they have limited applicability for quantitatively assessing human health risks associated with perchlorate exposure.

The NRC study also reviewed EPA's findings presented in the 2002 perchlorate risk assessment. A primary purpose of EPA's perchlorate risk assessment was to calculate a reference dose (RfD). The NRC study did not agree with the basis of the EPA's study, which relied on animal data. The NRC reviewed both human and animal data and found that the human data formed a better basis for risk assessments. The EPA study's draft RfD for perchlorate was 0.00003 mg/kg per day and the NRC study recommended an RfD of 0.0007 mg/kg per day. The NRC stated that this value is supported by other

clinical studies, epidemiologic studies, and studies of long-term perchlorate administration. The NRC report concluded that the proposed RfD of 0.0007 milligrams per kilogram per day should protect even the most sensitive populations. The EPA has established an official RfD of 0.0007 mg/kg/day of perchlorate consistent with this recommended RfD, which translates into a Drinking Water Equivalent Level of 24.5 ppb.

Noise

Prelaunch Activities

Prelaunch activities including evacuation and road closure activities and storing boosters, propellants, and kill vehicles would have no impact on noise.

Launch/Flight Activities

Launch activities would produce the same noise levels in all of the biomes considered in this PEIS. The potential for impact would depend on the specific launch location. Three possible issues must be addressed to determine potential noise impacts, including personnel safety, public safety, and public annoyance. The impact of noise from launches on biological resources is addressed in Biological Resources. Launches would not add new types or levels of noise to the current noise environment at existing launch sites. Noise levels produced by BMDS launches would be similar to past and current noise levels at launch sites. Launches would be relatively short noise events during which all personnel would be located in various control or blockhouses and therefore would be protected from noise by the sound attenuation provided by the building's construction. Zones in the operations area with high noise levels would be designated off-limits to non-essential personnel. Entry into these zones would be prohibited except to personnel wearing hearing protection that would reduce noise.

Sonic booms may be generated during launch or booster reentry. Each booster would propagate a unique sonic boom contour depending upon its mass, shape, velocity, and launch or reentry angle, among other variables. Areas affected by a sonic boom could extend up to several miles on each side of the focal point of the sonic boom. Sonic booms may produce overpressures as high as 8 to 16 pounds per square foot, but this would be of very short duration, lasting up to several milliseconds. (U.S. Army Space and Strategic Defense Command, 1994a) These levels of sonic booms can have minor effects on physical structures (glass failure, plaster may crack, etc.) but are not strong enough to cause injury to people.

Air Operating Environment. Noise generated by the booster launched from an air platform would reach the Earth's surface. Prior analyses of air-launched boosters showed that an Air Drop vehicle launched from an altitude of approximately 5,000 feet above MSL would generate approximately 115 dBA at ground level directly below the launch

point. (BMDO, 1998) The noise levels that reach the ground will vary depending on the altitude and attitude at which the booster is launched. This noise would decrease rapidly as the launch altitude increases; thus, launch noise would be brief.

Sea Operating Environment. Launches from sea platforms in the BOA would have fewer noise impacts because of the distance of the sea operating environment from population centers. Essential personnel would be located in an area of the sea launch environment that is protected from the noise generated during launch. Non-essential personnel would be moved to a safe distance and would be protected from the noise generated during launches. Personnel that may be exposed to loud noises would be required to wear hearing protection, such as earplugs or earmuffs, which would reduce noise levels to prescribed health and safety levels.

Postlaunch Activities

Impacts of noise from launch debris recovery activities on land are discussed below.

Launch Debris on Land. Vehicles used for booster and kill vehicle debris recovery operations (trucks and helicopters) on land would produce noise. Each recovery operation would be expected to last less than one day; thus, noise associated with debris recovery would not be a constant occurrence. Helicopter flight helmets would provide the required noise attenuation for the crew. Noise impacts from debris recovery operations would be minor.

Transportation

Prelaunch Activities

Prelaunch activities including booster fueling, road closure, and evacuations would not impact transportation. Road closures would be implemented in the areas around the launch site and along the expected trajectory. These temporary road closures would be of short duration and would be considered routine occurrences for launch sites. Prominent notices would be posted to notify the general public and local businesses of expected closures. Therefore, impacts on traffic are not expected to be significant. Existing agreements regarding road closures would be followed. These impacts would be the same in all of the biomes considered in this PEIS. Any disruption due to military convoys or roadblocks would be of short duration and would not be expected to have a significant impact on transportation.

Propellants for non-pre-fueled liquid propellant boosters would be transported from the storage facility to the fueling location in accordance with appropriate regulations and would not be expected to pose significant impacts to transportation.

Launch/Flight Activities

Issuance of NOTMARs is standard practice when a launch has the potential to impact marine areas and would allow marine vessels to clear the affected area; thus, launch activities would have no impact on marine transportation

In some biomes there are few roads and much of the transportation in the region occurs by airplane. Therefore, while launches may have little to no impact on ground transportation due to road closures, air transportation may be temporarily affected. NOTAMs would be issued prior to launch events that would notify pilots of proposed airspace closures and would permit pilots to find new routes or to delay their trip until after the airspace is reopened. Impacts to air transportation are discussed above in Airspace.

Postlaunch Activities

Impacts to transportation from debris recovery are addressed separately for land and water below.

Launch Debris on Land. Trucks and mobile ground equipment used for debris recovery operations for boosters and kill vehicles would travel both on- and off-road. Debris recovery requires a relatively small number of vehicles and therefore, is not expected to impact traffic or transportation infrastructure.

Launch Debris in Water. Debris from boosters and kill vehicles may fall into waters normally occupied by commercial shipping. The majority of international trade uses routes of least distance. The actual debris impact area for boosters and kill vehicles would be small and would depend upon the individual flight path. Prior warning of proposed launch activities through issuances of NOTMARs would enable commercial shipping to follow alternative routes away from the proposed debris impact area.

Water Resources

Prelaunch Activities

Adherence to existing policies and procedures would minimize the impacts from spills related to pre-fueled and solid propellant boosters and kill vehicles. Fueling of non-pre-fueled liquid propellant boosters would be conducted in accordance with approved procedures and all applicable regulations. All fueling would be conducted using appropriate impermeable barriers that would prevent spills from reaching bodies of water.

Launch/Flight Activities

Small amounts of hydrochloric and hydrofluoric acids would be generated from the launch of pre-fueled liquid propellant boosters. These acids could reach surface water if rainfall occurred within two hours of a launch. This is most likely to occur in the Arctic Tundra, Sub-Arctic Taiga, Deciduous Forest, and Mountain Biomes where rain is a frequent occurrence. In addition, hydrochloric acid could be produced in the Sub-Arctic Taiga, Chaparral, Grasslands, and Savanna Biomes when cool and humid conditions exist during launch activities. Given the dry conditions in the Desert Biome it is unlikely that chlorine would be converted to hydrochloric acid. The Tropical Biome is generally humid but the temperatures are not cool enough to convert the HCl produced as a result of launches to hydrochloric acid. In the BOA, the acid produced would be neutralized by calcium carbonate in ocean water. However, exhaust emissions from pre-fueled liquid propellant missiles would not significantly impact water quality.

Launch of solid propellant boosters could result in deposition of small amounts of Al_2O_3 from booster exhaust. This exhaust product could be deposited in surface waters. EPA has determined that Al_2O_3 as found in solid propellant exhaust is nontoxic. (NASA, 1990, as referenced in U.S. Army Space and Strategic Defense Command, 1994a) Al_2O_3 would be hazardous only in acidic biomes (pH less than 5) where it would dissociate into free aluminum cation. (FAA, 1996, as referenced in U.S. Army Space and Missile Defense Command, 2003)

In biomes where rain is a frequent occurrence, launches with solid boosters have an increased likelihood of contributing to acid rain, thereby increasing the amount of HCl deposited in regional surface waters. In areas with low velocity of surface and ground water movement and relatively shallow ground water table it is possible that deposition of acidic water may impact water resources. The potential for and extent of impact would need to be examined in site-specific environmental analysis.

In the absence of substantial surface and ground water bodies, launch exhaust emissions are unlikely to impact water resources. Additionally, in many desert areas, the ground water table is lower than six meters (20 feet) below ground level, which would inhibit contamination from surface pollutants. For example, the evaporation and deposition of dissolved solids in the water for thousands of years has formed a hardpan over much of the Tularosa Basin, which houses an aquifer that underlies WSMR, New Mexico, and Fort Bliss, Texas. The hardpan consists of impermeable silt and clay and aids in preventing pollution of the aquifer from the land surface. It is unlikely that the aquifer could be contaminated from surface seepage from the lower elevations of the basin. This eliminates any direct channeling to the water table. (Carmichael, 1986, as referenced in U.S. Army WSMR, 1991)

Postlaunch Activities

If residual liquid propellants were deposited in surface water (either in the ocean or in lakes or streams), nitric acid would cause a short-term pH change in the water body. The acid would mix with the water and eventually be neutralized and diluted. Hydrogen peroxide in surface water would decompose into water and oxygen within eight hours to 20 days. Kerosene or JP-8 fuel would not mix with the water, but would form a slick on the surface that would stick to surfaces it contacts. Hydrazine fuels would degrade primarily into N_2 gas and water over a period of hours to weeks, with degradation proceeding more rapidly in alkaline waters.

Impacts to water quality from a direct release on land are described in the hazardous waste section above.

Launch Debris in Water. In some instances, an early flight termination could result in propellant and debris deposition in water bodies. Some perennial surface waters could be impacted following a flight termination. However, the probability of any individual water body, spring, or creek being directly impacted is extremely low and would be a function of the amount of surface water in the impact area. An early flight termination also could possibly impact in an area of shallower ground water or an aquifer recharge zone. In any of these unlikely events, the appropriate officials would be notified.

In the event of a failure, effluents may enter water bodies if the debris impacts in surface water areas. These effluents could enter underground sources of drinking water in areas where there is a shallow ground water table. However, the release rates of materials that impact surface water would be such that no significant changes in surface water quality would be detectable.

The booster and kill vehicle would consist primarily of inert metal objects that would have little potential to contaminate water bodies. In general, a typical water contamination response would include

- Rendering the booster or debris safe,
- Stopping the flow of oxidizer or fuel,
- Neutralizing the oxidizer in the stream (or body of water) sufficiently far downstream so as to avoid a continuing hazard to water quality,
- Installing surface skimmers and absorptive materials downstream from the lead edge of contamination to collect the fuel,
- Monitoring the pH along the stream to ascertain that a background pH level has been established, and
- Removing all petroleum products from stream surfaces and returning the damaged area to an environmentally sound level.

Orbital Debris

Prelaunch Activities

No orbital debris would be produced from prelaunch activities.

Launch/Flight Activities

Orbital debris could be produced from launch/flight activities in the event of a booster failure while in the exoatmosphere. However, any debris would not be expected to remain in orbit for more than a short time, followed by deorbiting and eventual burn-up during reentry of the Earth's atmosphere.

Postlaunch Activities

A failure of a booster in the exoatmosphere may generate orbital debris. The type of orbital debris produced from a booster failure would be similar to that produced from a high altitude successful intercept. However, the amount of debris from a booster failure would be less than that produced from an intercept. The impacts of orbital debris from intercepts are discussed in Section 4.1.2.10 and were found to not pose significant impacts. Therefore orbital debris from a booster failure would similarly not pose significant impacts.

4.1.1.3 Sensors - Radars

As described in Exhibit 4-3, the analysis for radars is based upon impacts from the activation of the radar.

Air Quality

Activation emissions from radars would be limited to exhaust produced by generators. Impacts related to generator emissions are discussed in Support Assets. These impacts would be the same in all of the biomes considered in this PEIS.

Airspace

During activation of land-based radars, NOTAMs would be issued and pilots would be restricted from EMR hazard areas. NOTAMs would be sent in accordance with the conditions of the directive specified in Army Regulation 95-10, Operations to notify aircraft of EMR hazard areas during the activation of radars. Airspace restrictions would be short-term events and would not pose a significant impact on available airspace. Sufficient notice of restricted areas would be provided to allow pilots to select alternate flight paths to avoid restricted areas.

The activation of radars in the Sub-Arctic Taiga Biome may impact small civilian aircraft, which frequently transit the biome at low altitudes. Because many remote civilian airports within this biome do not have operating control towers, some aircraft pilots may be required to upgrade their communication equipment (at their own expense) to ensure that they are aware of activation activities and areas that must be avoided. Civilian aircraft would be required to contact local range control towers when transiting restricted airspace. The controllers would then be able to advise civilian pilots as to their proximity to hazard areas during activation of radars. (U.S. Army Space and Missile Defense Command, 2000) Other biomes including Arctic Tundra and the BOA are unlikely to experience impacts because small civilian aircraft would not readily occur in these regions. The Deciduous Forest, Chaparral, Grasslands, Desert, Tropical, Savanna, and Mountain Biomes are unlikely to experience impacts because these biomes are more likely to have operational control towers that could communicate with civilian aircraft.

For activation activities occurring in international airspace, procedures of the ICAO would be followed. ICAO Document 4444 is the equivalent air traffic control manual to the FAA Handbook 7110.65, Air Traffic Control. Personnel would ensure coordination with the ICAO through the FAA, to issue NOTAMs, locate ships with radar capable of monitoring the airspace, contact all commercial airlines and civil and private airports, and monitor appropriate radio frequencies to minimize potential safety impacts.

During activation of radars in the BOA, at least one Control Area Extension corridor in the BOA would remain available for use by general aviation and commercial air carriers.

Potential interference to aircraft electronic and emitter units (e.g., flight navigation systems and tracking radars) would be examined before activation of radars. A high-energy radiation area would be configured to mitigate potential impacts to aircraft and other potentially affected systems and a notice would be published on the appropriate aeronautical charts, notifying aircraft of the radio frequency radiation area. Boundaries of these radio frequency radiation areas would be configured to minimize impacts to aircraft operations and other potentially affected systems. In addition information would be published in the Airport Facility section of the FAA Airport Guide. Flight service personnel would brief pilots flying in the vicinity about the radio frequency radiation area. Radar operations would be coordinated with FAA and range officials and if possible would be programmed to limit radio frequency emissions in the direction of airways that pass within the potential interference distance.

EMR from radar activation may interact with and adversely affect aircraft operations by disabling or inadvertently initiating vital electronic equipment, including electroexplosive devices on-board aircraft. Electroexplosive devices on aircraft in flight could be illuminated by a radar main beam. Software controls and coordination with military and commercial aircraft controllers would eliminate this potential hazard. (U.S. Army Space and Missile Defense Command, 2003)

The FAA and DoD have standards, such as MIL-STD-464, for EMR interference with aircraft, which would not be exceeded. To operate in an affected area, military aircraft would have to be hardened or protected from EMR levels up to 3,500 volts per meter (peak power) and 1,270 volts per meter (average power). Commercial aircraft must be hardened or protected from EMR levels up to 3,000 volts per meter (peak power) and 300 volts per meter (average power) as mandated by the FAA by Notice 8110.71, Guidelines for the Certification of Aircraft Flying through High Intensity Radiated Field Environments. Radars would not exceed the 3,000 volts per meter power threshold.

Reducing the time on-board electronic equipment is exposed to EMR would lower the average power threshold experienced. (U.S. Army Space and Missile Defense Command, 2003) Commercial aircraft equipment would be affected only if the main beam illuminated the aircraft long enough to affect on-board electronics. Because radars are typically in constant motion, it is highly unlikely that a radar would illuminate an aircraft long enough to interfere with on-board electronics.

Activation impacts from air- and sea-based radars would be similar to those described for land-based radars. Radars located on sea-based operating environments would most likely be located far enough off the coast to not interfere with existing airfield or airport arrival and departure traffic flows. Activation of space-based radars would not be expected to impact airspace.

Biological Resources

Radar activation activities would produce the same impacts on biological resources in all of the biomes considered in this PEIS. The potential for main-beam exposure thermal effects to animals, especially birds, exists from the activation of land- and air-based radars. The *Final Ground-Based Radar Family of Radars Environmental Assessment* (1993) and *Ground-Based Midcourse Defense Extended Test Range Environmental Impact Statement* (2003) analyzed potential impacts on wildlife from EMR. Additional analysis is provided in this PEIS in Appendix N. Potential effects include exposure of birds to the main radar beam, which could result in thermal heating or interference with the navigation of migratory birds, EMR impacts from the COBRA DANE radar operating on Eareckson Air Station on Shemya Island, Alaska, bird collisions with radar and radar equipment, and effects in the near shore environment.

Appendix N evaluates under what conditions a BMDS radar beam could be sufficiently powerful to cause thermal heating or to interfere with the navigational ability of migratory birds. The proposed BMDS radars would operate within five different wavebands: UHF, L, S, C, and X bands. For each of the five bands, the most powerful type of radar operating in that band was evaluated. The representative radar from each band is PAVE PAWS for UHF, COBRA DANE for L-band, Aegis for S-band, MPS-36 for C-band and SBX for X-band.

The conservative analysis presented in Appendix N indicated that there is no concern for birds flying through radar beams emanating from the X-band, C-band and UHF radars. This applies to bird flights perpendicular to or in the direction of stationary beams, as well as for beams in surveillance mode. However, for the L-band COBRA DANE radar, there may be some risk to birds flying at flight altitudes of less than 1,700 meters above the radar, when the beam is elevated between four and fifty degrees above horizontal. This is a worst-case scenario for birds migrating from Alaska along the Pacific Oceanic migration route that might fly parallel to the COBRA DANE radar beam for a portion of their flight. Birds migrating from Alaska to Asia are likely to be flying more perpendicular or at an angle to the radar beam than parallel to the beam. For higher beam elevations and for lower flying birds, migrating birds flying parallel to the beam may not receive exposures above the no-harm reference value.

In Appendix N, MDA has considered mitigation measures to reduce the possible risks to migrating birds. The mitigation measures discussed in Appendix N include

- Evaluating the possibility that the COBRA DANE radar might be tested with stationary beams during spring and fall migrations.
- Evaluating whether the locations where the COBRA DANE radar would be used are in a significant migratory route or near to a migratory stopover, such that large migratory flocks might on occasion pass through the radar beam.
- Considering use of a local Next Generation Weather Radar (NEXRAD) to help evaluate when large flocks might be in the vicinity of the radar if a risk to migratory flocks is deemed to exist, so that the timing of a test does not coincide with particularly large flocks of birds flying close to the radar.

Bird collisions with radars and radar equipment also are a concern. MDA could mitigate this risk by using highly visible paints and a change in brightness of warning lights on the antenna towers and guy wires to minimize the potential for bird collisions with radar equipment. Overall, no significant impacts to birds would be expected from the operation of radars.

Potential impacts on wildlife from the activation of sea-based radars in the near shore environment would include seabirds and shorebirds, including migratory species, striking the antennas, telescopes, and shelters or becoming disoriented due to high intensity lighting at night. To minimize the occurrence of bird strikes, antennas would be raised only as necessary and colorful streamers or other visual indicators could be used to increase visibility to birds, if there is no interference with the operation of the radar. To prevent birds from becoming disoriented, high intensity lighting would be used only when necessary and low intensity lighting would be used whenever possible. Lighting would be adequate for safe working conditions but minimized to the extent practical.

Radar main beams on sea-based operating environments would not be directed toward the ocean surface, which would limit the probability of energy absorption by surface-oriented wildlife. The power density level just below the surface of the ocean where marine mammals may be located would not exceed the PEL for uncontrolled environments. (U.S. Department of the Navy, 2002a, as referenced in U.S. Army Space and Missile Defense Command, 2003) No adverse impact would occur to whales, other marine mammals, or sea turtles found at least 1.3 centimeters (0.5 inch) below the surface. It is also highly unlikely that an individual would be on or substantially above the surface of the water for a significant amount of time within the main beam area during radar activation. Therefore, no impacts are anticipated to whales, other marine mammals, or sea turtles that might be present in the vicinity of the radar.

Previous analysis (U.S. Army Space and Missile Defense Command, 2003) has shown the potential EMR interference distance for fully-populated XBR to be only 19 kilometers (12 miles). Because space-based platforms would be placed in LEO or GEO at altitudes ranging from approximately 160 to 1,600 kilometers (100 to 1,000 miles) for LEO and approximately 35,000 kilometers (21,700 miles) or greater for GEO, it is expected that EMR would not reach Earth; thus, the activation of space-based radars would not be expected to impact biological resources.

Geology and Soils

Radar activation activities would produce the same impacts on geology and soils in all of the biomes considered in this PEIS. Impacts to geology and soils from activation of radars would be limited to accidental spills of diesel fuel from generators used to support the activation of radars. Potential impacts from releases of diesel fuel are discussed in Support Assets.

Hazardous Materials and Hazardous Waste

Radar activation activities would produce the same hazardous materials and hazardous waste impacts in all of the biomes considered in this PEIS. The types of hazardous materials used and waste generated would be similar to those currently used and generated at military installations. Antifreeze and fire suppressants would be used for radar electronic systems. Cooling equipment units would use coolant fluids, such as a mixture of ethylene glycol and water. In addition, radar components and antenna units may require periodic application of petroleum-based lubricating oils. Used petroleum, oil, and lubricants would be generated in smalls amounts are not normally considered hazardous waste (designation varies by state). (U.S. Army Space and Strategic Defense Command, 1993c) All hazardous materials used and hazardous waste generated during the activation of land- and air-based radars would be handled in accordance with applicable regulations. Accidental releases of hazardous materials would be contained in accordance with site-specific spill plans.

Temporary storage tanks and other facilities for the storage of hazardous materials would be located in protected and controlled areas designed to comply with SPCC plans. Hazardous wastes generated during radar activation activities may consist of materials such as waste oils, hydraulic fluids, cleaning fluids, cutting fluids, and waste antifreeze. The minimal quantities of hazardous waste that could potentially be generated would be disposed of in accordance with appropriate waste disposal regulations.

Impacts from hazardous materials and hazardous waste management for sea-based radars would be similar to those described for land- and air-based radars. The U.S. Navy requires that, to the maximum extent practical, ships retain hazardous waste onboard for shore disposal. If hazardous materials are discharged overboard, this must occur more than 370 kilometers (200 nautical miles) from land. Discharging hazardous materials overboard is not standard practice and would only be done in emergency situations. Twenty-five liquid discharges, such as clean ballast, deck runoff, and dirty ballast, from normal operation of military vessels are required to be controlled by installation of control technologies or use of management practices (marine pollution control devices) under the Uniform National Discharge Standard provisions of the Clean Water Act. In compliance with Uniform National Discharge Standards, the sea-based operating environment would incorporate marine pollution control devices, such as keeping decks clear of debris, cleaning spills and residues, and engaging in spill and pollution prevention practices, in design or routine operation.

Health and Safety

Radar activation activities would produce the same impacts on health and safety in all of the biomes considered in this PEIS. Safety precautions for handling, storing and transporting hazardous materials and hazardous waste releases would be followed at sites involved in BMDS activities. Each site would follow spill control and emergency response plans that would provide response actions for cleanup. Sites would maximize on-site and off-site recycling to reduce the need for waste disposal sites and handle or dispose of hazardous materials or wastes in compliance with all applicable laws, regulations, and guidance. (U.S. Army Space and Strategic Defense Command, 1993b)

Prior to activation of radars, an EMR survey would be conducted that considers hazards of EMR to personnel, to fuels, and to ordnance. The analysis would provide recommendations for sector blanking and safety systems to minimize exposures. Appropriate safety exclusion zones would be established before operation, and warning lights to inform personnel when the system is operating and emitting EMR would be installed.

Personnel exclusion areas would be established to protect personnel from potential EMR hazards during radar activation. Personnel not involved in test event activities would not be permitted to enter established hazard zones during the activation of radars. EMR

hazard zones would be established within the main beam's tracking space near emitter equipment. A visual survey of the area would be conducted to verify that all personnel are outside of the hazard zone prior to activation. Safety exclusion zones would also be established around generator wiring and cabling to protect personnel from high voltage exposure.

Potential health and safety hazards associated with the operation of radars were analyzed in previous documents. Two examples of these are *Ground-Based Radar Family of Radars Environmental Assessment* (1993) and *Environmental Assessment for Theater Missile Defense Ground-Based Radar Testing Program at Fort Devens, Massachusetts* (1994). These analyses considered operational requirements and restrictions and range-required safety procedures. It was determined that implementing safety procedures, including establishing controlled areas and limitations in the areas subject to illumination by radars, would preclude any potential safety hazard to either the public or project-related personnel from exposure to EMR.

The analysis method used to evaluate potential impacts of radio frequency radiation is the IEEE Maximum Permissible Exposure (MPE), which defines the maximum time-averaged radio frequency power density allowed for uncontrolled human exposure. The MPE method is independent of body size or tissue density being exposed. EMR hazard zones provide a safety factor 10 times greater than the MPE. MPEs are capped at 5 megawatts per square centimeter for frequencies greater than 1,500 MHz. (IEEE C95.1-1999, Standard for Safety Levels with Respect to Human Exposure to Radiofrequency EM Fields, 3 kilohertz to 300 GHz) General public exposure is typically limited to one fifth of the occupational limits.

At X-band frequencies, the IEEE standard for human exposure is 5.33 megawatts per square centimeter. For radars to have an effect on human health, the beam operating at full power would have to come in contact with a person and remain on them for 7.5 minutes (at 8,000 MHz) or 11.25 minutes (at 12,000 MHz). (U.S. Army Space and Missile Defense Command, 2003) The beam would normally be in motion, which would reduce the likelihood that a person would remain within the most intense area of the beam for any considerable length of time.

In addition to the impacts described above, activation of radars on sea-based operating environments would be coordinated with the FAA, U.S. Coast Guard, and other groups or agencies as appropriate. The implementation of software controls would prevent a radiation hazard zone from occurring on the deck of the sea-based operating environment.

Noise

Radar activation activities would produce the same noise impacts in all of the biomes considered in this PEIS. Noise impacts associated with activation of radars would be limited to noise produced by generators. Impacts related to generator noise are discussed in Support Assets.

Transportation

The activation of radars has the potential to impact air transportation. These impacts are discussed in Airspace. These impacts would be the same in all of the biomes considered in this PEIS.

NOTMARs would be issued in advanced of test events; therefore, commercial marine vessels would be able to choose transportation routes outside of proposed radar activation areas.

Water Resources

Additional personnel would be needed for the activation of radars; these personnel would increase the demand for potable water. An increase in demand could exceed the capacity of the existing infrastructure at some locations. (U.S. Army Space and Missile Defense Command, 2003) This is of particular concern in portions of the Sub-Arctic Taiga, Grasslands, Desert, Tropical, and Mountain Biomes. It is anticipated that additional packaged potable water systems would be installed to meet the demands in areas where access to potable water is limited. Site-specific studies should consider the limited potable water supplies in these areas when analyzing the impacts to water resources from the proposed activation of radars. Other biomes including Arctic Tundra, Sub-Arctic Taiga, Deciduous Forest, Chaparral, and Savanna Biomes are unlikely to experience impacts to water resources. Due to ample ground water supply, it is unlikely that a significant increase in demand would exceed the capacity of existing infrastructure in these biomes.

Impacts to water resources from activation of radars would include potential release of hazardous materials. Materials released from sea-based operating environments would be rapidly diluted and would not be found at concentrations identified as producing any adverse impacts due to the high buffering capacity of sea water in the open ocean. The ocean depth in the vicinity of sea-based radar would most likely be thousands of meters deep, and consequently, any impact from fuel or hazardous material spills would be minimal. From land- and air-based operating environments, impacts from hazardous materials releases would depend on the characteristics of the water bodies in the respective biome. No impacts to water resources would occur as a result of space-based sensors that would be in GEO.

Orbital Debris

No impacts from orbital debris would occur as a result of the activation of land-, air-, and sea-based radars.

Orbiting objects lose energy through friction with the upper atmosphere and various other orbit perturbing forces. Over time, an object may drop into progressively lower orbits and may eventually fall to Earth. As the object's orbital trajectory draws closer to Earth, it speeds up and outpaces objects in higher orbits. Once the object enters the measurable atmosphere, atmospheric drag will slow it down rapidly and cause it either to burn up or deorbit and fall to Earth.

Space-based radars could reenter the Earth's atmosphere due to failure, but would not likely result in significant impacts. Most objects break up and often vaporize under the intense aerodynamic forces and heating that occur during reentry. Most of the objects which reenter would fragment and burn in the upper atmosphere and would make only negligible changes in its chemical composition. An estimated 500 objects and thousands of debris fragments reenter the Earth's atmosphere each year; however, few survive reentry. Out of approximately 3,100 objects from 44 launches between 1956 and 1972, only 100 have survived reentry and been recovered. Even if an object does survive reentry, only one third of the Earth is land area, and only a small portion of this land area is densely populated. The chance of hitting a populated land area upon reentry would be small. (SDIO, 1992)

4.1.1.4 Sensors - Infrared and Optical Sensors

As described in Exhibit 4-3, the analysis for infrared and optical sensors is based upon impacts from the activation of the sensors.

Air Quality

Activation emissions from infrared and optical sensors would be similar to those discussed for radars. These impacts would be the same in all of the biomes considered in this PEIS.

Airspace

No impacts to airspace would be expected due to the activation infrared and optical sensors.

Biological Resources

No impacts to biological resources would be expected due to the activation infrared and optical sensors.

Geology and Soils

Impacts to geology and soils from activation of infrared and optical sensors would be similar to those discussed for radars. Infrared and optical sensor activation activities would produce the same impacts on geology and soils in all of the biomes considered in this PEIS.

Hazardous Materials and Hazardous Waste

Impacts to hazardous materials and hazardous waste from activation of infrared and optical sensors would be similar to those described for radars.

Health and Safety

Safety exclusion zones would be established around generator wiring and cabling to protect personnel from high voltage exposure. These impacts would be the same in all of the biomes considered in this PEIS.

Noise

Noise impacts associated with activation of infrared and optical sensors would be similar to those described for radars. These impacts would be the same in all of the biomes considered in this PEIS.

Transportation

There would be no impacts to transportation from the activation of infrared and optical sensors.

Water Resources

Impacts to water resources from activation activities would be similar to those described for radars. These impacts would be the same in all of the biomes considered in this PEIS.

Orbital Debris

Impacts from orbital debris related to space-based sensor activities would be similar to those described for radars. See Section 4.1.1.3.

4.1.1.5 Sensors - Laser Sensors

As described in Exhibit 4-3, the analysis for laser sensors is based upon impacts from the activation of the sensor.

Air Quality

Laser sensor activation activities would produce the same air quality impacts in all of the biomes considered in this PEIS. Laser sensors include gas lasers and solid-state lasers that expend low-level infrared radiation to form a focused laser beam. (MDA, 2003a) Potential emissions produced during activation would depend on chemicals used. These emissions would typically be released to the air where the impacts would be as discussed below.

The operation of a CO_2 gas laser sensor, like the Active Ranging System (ARS) laser associated with the ABL, would include the use of helium, N_2, and CO_2. (MDA, 2003a) None of these inert gases are considered hazardous; however, they can be asphyxiants, replacing oxygen to create oxygen-deficient conditions. A leak of these gases to the atmosphere would be insignificant relative to ambient oxygen concentrations. Impacts from asphyxiants would occur only in confined areas. Gas laser sensors could use a glycol (Refrigerant 404) closed-loop cooling system. Refrigerant 404 is an ozone-depleting substance; however, the closed-loop system would prevent releases to the atmosphere. In the unlikely event that a release does occur during testing or activation, the small amount released would quickly be dispersed and would not significantly impact air quality.

Solid-state lasers like the Beacon Illuminator Laser (BILL) and the TILL associated with the ABL have crystals as the active medium. Operation of these lasers causes thermal expansion of the crystal, which alters the effective cavity dimensions, thus changing the mode structure of the laser. The lasers are cooled by non-hazardous liquids such as water and deuterium oxide, which are in closed looped systems. No pollutant emissions are associated with the testing and activation of these lasers, therefore no impacts to air quality would be expected.

Airspace

The use of laser sensors would occur in cleared airspace within designated airspace areas. Close coordination with the FAA ARTCC and relevant military installations with responsibility for airspace management would minimize the potential for any adverse impact on airspace use. Lasing activities would be suspended immediately when ground observers using binoculars indicate an aircraft might be approaching the area; therefore, no impacts to airspace would be expected. Laser sensor activation activities from the

ground would produce the same airspace impacts in all of the biomes considered in this PEIS.

Flight-testing and activation activities for air-based laser sensors would occur at altitudes greater than 10,671 meters (35,000 feet) above MSL. Targets would be actively engaged at or above 10,671 meters (35,000 feet) above MSL, and would not engage below the 10,671 meters (35,000 feet) horizon. This would ensure activation of the laser sensors at an upward angle from the 10,671 meters (35,000 feet) horizon, and thus above commercial aircraft traffic and away from the Earth's surface. Due to the negative impacts of cloud cover on sensing lasers and the increase in air traffic below the 10,671 meters (35,000 feet) horizon, activation of lasers in a deployed situation would be conducted above the 10,671 meters (35,000 feet) horizon as well.

Activation of lasers would occur in cleared airspace within designated airspace use. Close coordination with the FAA ARTCC and relevant military installations with responsibility for airspace management would minimize the potential for any adverse impacts on airspace use.

Biological Resources

Impacts to biological resources as a result of activation of laser sensors could occur. Ground testing of air-based lasers has the greatest potential for impacts. Wildlife in the beam path of the laser could suffer eye damage as a result of the laser activation. Due to the short duration of the laser operations during testing and the small range area used for the ground testing, impacts to wildlife would be insignificant. Laser sensor activation activities would produce the same biological resource impacts in all of the biomes considered in this PEIS.

Flight-testing and activation of air-based laser sensors would occur at an altitude of 10,671 meters (35,000 feet) above MSL or greater. Impacts from the laser operation on biological resources on the ground would be insignificant. Birds in the beam path of the laser could suffer eye damage as a result of the laser activation. However, bird densities at 10,671 meters (35,000 feet) above MSL would be extremely low, and the time of exposure to the beam path would be extremely low as well. Also, because the laser beams from solid-state laser sensors are usually not continuous, but consist of a large number of separated or pulsed power bursts, it is highly unlikely that a bird would remain within a beam for any considerable length of time. Therefore, significant impacts to birds would not be expected. (MDA, 2003a)

Impacts from the activation of land-, and sea-based lasers would be insignificant. The beam path of land-, and sea-based lasers would be directed at an upward angle from the Earth's surface, and thus would not impact biological resources on the ground. Impacts

to birds and from beam reflection would be similar to those described for air-based laser sensors.

Impacts to biological resources as a result of testing and activation of space-based laser sensors would be insignificant. In the unlikely event that the laser was directed towards the Earth's surface, distortion from atmospheric conditions would reduce the radiance level of the lasers. The ANSI refers to the eye hazard distance as the Nominal Ocular Hazard Distance. This distance is defined as "the distance along the (propagation) axis of the unobstructed beam from a laser … to the human eye beyond which the … exposure … is not expected to exceed the appropriate MPE." (MDA, 2003a)

The Earth's surface would likely be beyond the Nominal Ocular Hazard Distance of the laser sensor, and thus, the impacts would be insignificant.

Geology and Soils

No impacts to geology and soils would occur as a result of activation of land-, sea-, air-, and space-based laser sensors. The only hazardous material that would be used to cool gas laser sensors is a gas at ambient conditions and would not impact geology and soils.

Hazardous Materials and Hazardous Waste

Laser sensor activation activities would produce the same hazardous materials and hazardous waste impacts in all of the biomes considered in this PEIS. The types of hazardous materials used and waste generated would be similar to those currently used and generated at military installations. No hazardous materials would be used during activation of lasers. Gas laser sensors would use CO_2, helium and N_2 to generate the laser, but these substances are not hazardous. These gases would be held in compressed gas tanks and would be handled according to all applicable Federal, state, and local regulations. Gas laser sensors would use a glycol (Refrigerant 404) cooling system. (MDA, 2003a) Refrigerant 404 is an ozone-depleting substance. However, the cooling system would be a closed loop system, and the refrigerant would be replaced only during routine maintenance. Used refrigerant would be handled and disposed of or recycled according to all applicable Federal, state, and local regulations. Accidental releases of hazardous materials would be contained in accordance with a site-specific spill plan.

Solid-state laser sensors would use non-hazardous crystals as the laser generating medium. These sensors could use either water or deuterium in their cooling systems. (MDA, 2003a) These non-hazardous coolants would be contained in closed-loop systems and would be recycled or replaced as needed.

Health and Safety

Laser sensor activation activities would produce the same impacts on health and safety in all of the biomes considered in this PEIS. Laser sensors are created by chemical reactions that release low levels of energy in a focused energy beam that is invisible to the naked eye. Despite its relatively low energy level, the laser beams can be hazardous to the eyes of living organisms within a certain proximity (or hazard distance) specific to the parameters of the laser beam. The MPE of the laser's energy is the standard that indicates "the level of laser radiation to which a person may be exposed without hazardous effect or adverse biological change in the eye." (ANSI Z136.1, *Safe Use of Lasers*, as referenced in MDA, 2003a) The MPE is a function of laser wavelength and exposure duration, but also varies based on waveform (pulsed or chopped), and the waveform's respective parameters (e.g., for pulsed waves, pulse width and pulse repetition frequency are additional factors in the MPE calculation).

The MPE and output parameters, such as power and divergence or beam spread, can be used to evaluate the hazard at various proximities, known as the eye hazard distances. ANSI refers to the eye hazard distance as the Nominal Ocular Hazard Distance. This distance is defined as "the distance along the (propagation) axis of the unobstructed beam from a laser … to the human eye beyond which the … exposure … is not expected to exceed the appropriate MPE."

Laser light is predominantly scattered forwards and backwards, whereas relatively little is scattered sideways. Therefore, an organism would have to look straight down the beam to be at risk. Some laser beams, such as those produced by gas laser sensors, diverge once they leave the sensor, therefore a lower hazard risk would be expected as the distance between the source sensor and a receptor increases. Other laser beams, like those produced by solid-state laser sensors, may maintain or increase their focus once they leave the sensor. When the laser's focus is maintained instead of diverging, the laser may become hazardous to an organism's eyes at a certain distance (e.g., two kilometers) before the primary focus point and stay hazardous until that same distance (e.g., two kilometers) after the primary focus point. (MDA, 2003a)

The DoD follows limitations outlined in ANSI Z136.1, *Safe Use of Lasers*, for the testing and activation of laser sensors. The limitations include establishing a restricted area excluding all but authorized and properly trained personnel, displaying warning signs designating the restricted area, removing reflective surfaces, and incorporating automatic hard-stop limits and/or laser blanking devices. This last measure would ensure that laser energy does not extend beyond natural features or backstops during testing scenarios. (MDA, 2003a) Safety exclusion zones would be established around generator wiring and cabling to protect personnel from high voltage exposure.

Noise

Noise impacts associated with activation of laser sensors would be similar to those discussed for radars. These impacts would be the same in all of the biomes considered in this PEIS.

Transportation

Testing and activation of land-, sea-, air-, and space-based lasers could impact the use of airspace. These impacts are discussed in the Airspace section. These impacts would be the same in all of the biomes considered in this PEIS.

Water Resources

Laser sensor activation activities would produce the same impacts on water resources in all of the biomes considered in this PEIS. Gases used to generate gas laser sensors are inert and would not impact water resources through atmospheric deposition. Refrigerant 404 would be used to cool gas laser sensors in a closed loop system. In the unlikely event of a spill or leak, the coolant becomes a gas under ambient conditions and would not impact water resources.

Solid-state laser sensors would use either water or deuterium oxide as a coolant. Deuterium oxide is water that contains a significantly higher proportion of deuterium atoms to ordinary hydrogen atoms. The laser coolants would operate within a closed-loop system and are only replaced during general maintenance requirements. The cooling liquids are non-hazardous and would not be expected to impact water resources.

Orbital Debris

Impacts from orbital debris related to space-based laser sensor activation activities would be similar to those described for radars. See Section 4.1.1.3.

4.1.1.6 C2BMC - Computer Terminals and Antennas

As described in Exhibit 4-3, the analysis for computer terminals and antennas is based upon impacts from the activation of the computer terminals and antennas. Impacts from site preparation and construction activities related to computer terminals and antennas are addressed in Support Assets.

Air Quality

Activation emissions from computer terminals and antennas would be limited to exhaust produced by generators. Impacts related to generator emissions are discussed in Support Assets. These impacts would be the same in all of the biomes considered in this PEIS.

Airspace

Activation activities for computer terminals and antennas would have the potential to impact airspace use by utilizing radio transmission frequencies, which may interfere with commercial air traffic control communications. The magnitude of the impact on airspace would depend on the specific location proposed. In accordance with standing regulations, MDA would coordinate radio frequency use and testing with the appropriate air traffic control agencies. A re-radiation tower is a transmission and receiving tower used in conjunction with fiber optic cable to verify the communication link between radar and an interceptor missile. Re-radiation towers can be built to heights of 31 meters (100 feet) and could impact airspace as collision hazards if constructed adjacent to airports and airfields. MDA would coordinate tower siting with the appropriate air traffic control agencies to avoid conflicts with established takeoff and landing patterns.

Biological Resources

Activation activities for land-, sea, and air-based computer terminals and antennas would have the potential to impact biological resources. The level of impact would vary based on the frequency and energy of the signal, and the proximity of the source to sensitive environments or specific threatened or endangered species, as well as the specific location proposed. In accordance with standing regulations, MDA would coordinate radio frequency use and testing with the appropriate resource management agencies.

Re-radiation towers are built to heights of up to 31 meters (100 feet). There is a potential risk of bird collisions with these towers. MDA could mitigate this risk by using highly visible paints and warning lights on the towers.

Space-based computer terminals and antennas would be in GEO and would have no impacts on biological resources.

Geology and Soils

Impacts to geology and soils from computer terminals and antennas would be limited to site preparation and construction activities. These activities are discussed in Support Assets. No impacts to geology and soils are anticipated as a result of the activation of computer terminals and antennas in any biome considered for this PEIS. (U.S. Army Space and Missile Defense Command, 2002d)

Hazardous Materials and Hazardous Waste

Regular maintenance and operation activities at land-based computer terminal and antenna sites would involve a continuous but relatively low level of hazardous materials use. These activities would produce the same hazardous materials and hazardous waste in all of the biomes considered in this PEIS. The anticipated amounts of hazardous materials used at the site are not known but are expected to be small. They could include protective coatings, lubricants and oils, motor and generator fuels, cleaning agents (isopropyl alcohol), backup power batteries, adhesives, and sealants. (U.S. Army Space and Missile Defense Command, 2002d) The use and disposal of these materials would be incorporated into hazardous material and waste management documents, such as an SWPPP and an Oil and Hazardous Substance Discharge Prevention and Contingency Plan. (U.S. Army Space and Missile Defense Command, 2002d) The hazardous materials would be stored in a centralized location for distribution when needed for maintenance. Material Safety Data Sheets would be posted at all locations where hazardous materials are stored or used. A site-specific hazardous materials management plan and an SPCC plan would be developed for the sites. (U.S. Army Space and Missile Defense Command, 2002d) The use and storage of hazardous materials would be in accordance with these regulations and applicable Federal, state, and local regulations. A Pollution Prevention Plan would be implemented for the proposed sites. This plan would control and reduce the use of hazardous materials at the installation site. (U.S. Army Space and Missile Defense Command, 2002d) In addition, the program would comply with any existing base Pollution Prevention Plan. Program personnel would continue to update the system-wide Pollution Prevention Plan, which would outline strategies to minimize the use of hazardous materials over the life cycle of the facilities.

Any hazardous waste generated from the use of these materials would be handled in accordance with appropriate Federal, state, and local regulations. Site-specific hazardous waste management plans would be in place for the operation and maintenance of the sites. If a release were to occur, all hazardous waste would be handled in accordance with appropriate regulations. In addition, a trained spill containment team would manage any release of hazardous waste at the site. (U.S. Army Space and Missile Defense Command, 2002d)

Health and Safety

Activation activities for computer terminals and antennas would have the potential to impact the health and safety of MDA personnel and the general public through the use of radio transmission frequencies and hazardous materials. These activities would produce impacts in all of the biomes considered in this PEIS; however, the impact would vary based on the site selected. The level of impact would vary based on the frequency and energy of the signal, the amount of hazardous materials to be used, and the proximity of the source to MDA personnel or the general public. MDA would train operating

personnel in the operation and maintenance of C2BMC equipment, and would not direct or use C2BMC equipment in a manner that would adversely impact the health and safety of the general public.

Noise

Computer terminal and antenna activation would produce the same type of noise in all biomes considered in this PEIS. Noise impacts associated with activation of computer terminals and antennas would be limited to noise produced by generators. Impacts related to generator noise are discussed in Support Assets.

Transportation

Impacts to transportation due to activation of computer terminals and antennas would be minimal in all biomes considered for this PEIS. Personnel operating and maintaining the components would generate the only traffic as a result of the activation. Personnel would be on site only during operational hours and during routine maintenance activities. (U.S. Army Space and Missile Defense Command, 2003) Impacts as a result of activation would be insignificant.

Water Resources

Additional personnel would be needed for the activation of computer terminals and antennas; these personnel would increase the demand for potable water. Potable water demands associated with the activation activities would be relatively minimal. However, an increase in demand could exceed the capacity of the existing infrastructure. (U.S. Army Space and Missile Defense Command, 2003) This is of particular concern in portions of the Sub-Arctic Taiga, Grasslands, Desert, Tropical, Mountain, and Savanna Biomes where access potable water may be limited. Additional packaged potable water systems could be installed to meet the demands. Site-specific studies should consider the limited potable water supplies in these areas when analyzing the impacts to water resources from the proposed activities. In other biomes including Arctic Tundra, Sub-Arctic Taiga, Deciduous Forest, and Chaparral Biomes, water resources are generally not scarce and therefore, it is unlikely that water demand from additional personnel associated with activation of computer terminals and antennas would exceed the existing capacity. However, there may be site-specific or localized water resource availability issues and these should be considered for any biome.

Operation of the components would have negligible effects on water quality. Implementation of a SWPPP and best management practices would reduce the risk of impacts from erosion and sedimentation to nearby surface waters. Compliance with the SPCC Plan would minimize the potential for accidental spills of hazardous materials and hazardous wastes to affect surface and ground water resources.

Space-based computer terminals would be in GEO and would have no impacts on water resources.

Orbital Debris

Space-based computer equipment could reenter the Earth's atmosphere due to failure, but would not likely result in significant impacts. Impacts from orbital debris related to space-based computer terminal and antenna activation activities would be similar to those described for radars. See Section 4.1.1.3.

4.1.1.7 C2BMC - Underground Cable

As described in Exhibit 4-3, the analysis for underground cable is based upon impacts from the activation of the underground cable.

Air Quality

Air quality impacts associated with underground cable would be limited to ground disturbances resulting from construction activities. These impacts are discussed in Support Assets. Activation activities related to underground cable would not have any impact on air quality in any biome considered for this PEIS.

Airspace

The activation of underground cable would not have any impact on airspace in any biome considered for this PEIS.

Biological Resources

Impacts to biological resources may occur during site preparation, these impacts are discussed in Support Assets. Activation of underground cable would not result in any impacts to biological resources in any biome considered in this PEIS.

Geology and Soils

Impacts to geology and soils would be limited to site preparation activities. Activation of underground cable would not result in any impacts to geology and soils in any biome considered in this PEIS.

Hazardous Materials and Hazardous Waste

Impacts from hazardous materials and hazardous wastes would be limited to site preparation activities. No hazardous materials or wastes would be generated from the

activation of terrestrial and marine underground cable. Therefore, no significant impacts from hazardous materials or hazardous waste would be expected in any biome considered in this PEIS.

Health and Safety

Potential health and safety hazards from site preparation include dust/particulate inhalation, improper chemical handling, and improper use of machinery; these impacts are discussed in Support Assets. No impacts to health and safety would be expected from activation-related activities in any biome considered in this PEIS.

Noise

The activation of underground cable would not produce noise that has the potential to impact sensitive receptors.

Transportation

There would be no significant impact to transportation from activation underground cable in any biome considered in this PEIS. Any necessary repairs to underground cable would require excavation of the cable. These maintenance activities could result in impacts to transportation through movement of equipment and personnel to the repair site. However, repair events would occur infrequently and would require much less activity than that needed for construction. Therefore, impacts to transportation would be insignificant.

Water Resources

Potable water demand for the installation and activation of underground cable would be small. Impacts from the demand for potable water associated with an increase in the number of project related personnel would be as described for Water Resources for Computer Terminals and Antennas. Impacts to water resources may occur during site preparation, particularly in marine environments. These impacts are discussed in Support Assets.

Orbital Debris

The use of underground cable would have no impact on orbital debris.

4.1.1.8 Support Assets - Equipment

Support equipment includes transportation and portable equipment (e.g., automotive, ships, aircraft, rail, generators, cooling units, storage tanks, chemical transfer equipment,

aerospace ground equipment), BMDS Test Bed support equipment (e.g., aircraft, vehicles, ships, mobile launch platforms, operator control units, sensor operations equipment [antenna, electronic equipment, cooling equipment, prime power units]), and weapons basing platform equipment (e.g., Heavy Expanded Mobility Tactical Truck with Load Handling System, Aegis Cruiser, ABL aircraft), as discussed in Section 2.2.4.1 and Section 4.0. This equipment is part of the military services inventory and is used to support mission-related activities.

MDA reviewed the impact analyses and conclusions in previously prepared site-specific NEPA documentation, specifically for the use of transportation of equipment and use of general portable equipment. The use of this type of support equipment has been analyzed in a number of previously prepared documents, including the *Ballistic Missile Defense Programmatic Environmental Impact Statement* (BMDO, 1994); *Ground-Based Midcourse Defense Initial Defense Operations Capability at Vandenberg Air Force Base Environmental Assessment* (MDA, 2003b); *Ground-Based Midcourse Defense Extended Test Range Environmental Impact Statement* (U.S. Army Space and Missile Defense Command, 2003); *National Missile Defense Deployment Environmental Impact Statement* (U.S. Army Space and Missile Defense Command, 2000); *Theater Missile Defense Extended Test Range Supplemental Environmental Impact Statement* (U.S. Army Space and Strategic Defense Command, 1998a); *Theater Missile Defense Extended Test Range Environmental Impact Statement* (U.S. Army Space and Strategic Defense Command, 1994a): *Evolved Expendable Launch Vehicle Program Environmental Impact Statement* (U.S. Department of the Air Force, 1998); *Point Mugu Environmental Impact Statement/Overseas Environmental Impact Statement* (U.S. Department of the Navy, 2002b); and *Pacific Missile Range Facility Enhanced Capability Environmental Impact Statement* (U.S. Department of the Navy, 1998). The use of general portable equipment and transport of equipment as defined in the previously prepared NEPA documents would not result in a significant impact.

For example, analyses on generator and transportation emissions conducted at KLC showed that emissions associated with the use of the facility and associated equipment for missile defense activities would be below the 90.7-metric-ton (100-ton) per year criteria pollutant Federal *de minimis* levels that apply to a non-attainment area. However, the use of certain generators would require an amendment to the existing Pre-approved Limit Permit for KLC. (U.S. Army Space and Missile Defense Command, 2003)

In addition, at Vandenberg AFB, procedures are in place so target missile launches would not represent a significant new impact on transportation, including air traffic, vehicular traffic, rail traffic, and marine traffic. (U.S. Army Space and Strategic Defense Command, 1994) Other transportation analyses found that the use of aircraft and commercial ground transportation vehicles to ship equipment from various manufacturing locations to basing locations would result in minor air emissions that were determined to be less than significant.

In many instances, transportation activities can be categorically excluded from further NEPA analysis. In accordance with DoD regulations for implementing NEPA (32 CFR 188), CEQ regulations provide for the establishment of categorical exclusions (40 CFR 1507.3(b)) for those actions, which do not individually or cumulatively have a significant impact on the human environment. Where appropriate, DoD has established such categorical exclusions. For example, infrequent, temporary (less than 30 days) increases in air operations up to 50 percent of the typical installation aircraft operation rate, are categorically excluded.

Review of previously prepared NEPA analyses and existing categorical exclusions have indicated that impacts associated with transportation would not be significant. Transportation activities would be performed in accordance with existing operating procedures and appropriate regulations, as well as in accordance with appropriate NEPA analyses. The shipment or transportation of hazardous and non-hazardous materials would be performed in accordance with applicable DOT standards, as well as established handling and transfer procedures. Proper containment, handling procedures, separation of reactive chemicals, and worker warning and protection systems would be used where necessary. Site-specific spill prevention guidelines, including leak detection and spill control measures, would be followed. However, if the proposed BMDS would increase transportation activities or result in the use of mobile support assets over existing levels or over what has been determined to be categorically excluded, site-specific NEPA analyses might be required.

As discussed above, general portable equipment has been considered in previously prepared NEPA analyses. These analyses demonstrate that the impacts associated with their use would not be significant. The use of some specific element support equipment has also been previously analyzed, and the impacts associated with their use would not be significant.

The use and operation of support equipment would be in accordance with installation-specific requirements that consider impacts on local, regional, and global environmental resources. The ongoing activities that occur at specific installations would be performed in accordance with appropriate Federal, state, and local regulations, and therefore would not be expected to result in a significant impact. Potential operational limitations include restrictions on timing, duration, or operational requirements as dictated through consultations and memorandums of agreement with appropriate regulatory agencies.

The following sections present the impacts associated with operational changes including implementation of new operating parameters for existing support equipment. These operational changes have not been previously analyzed or categorically excluded.

Air Quality

An increase in use of support equipment that results in increased emissions of a criteria pollutant, of a HAP, or of pollutants that affect regional haze could impact air quality. The significance of such impacts on air quality depends on the local or regional regulatory setting as well as the physical climate conditions where the emissions would occur. The regulatory setting includes EPA recognized non-attainment and maintenance areas, areas that have submitted regional haze SIPs to EPA, and locations that have sensitive receptors to HAP emissions. Each of the regulated areas occurs throughout the U.S. and its territories, which include all of the biomes except for the BOA and the Atmosphere.

The physical climate conditions that would affect the intensity and severity of the impact include regions that have periods of air inversions or other climatic conditions that does not permit normal air circulation or turnover to occur. Such conditions occur in the Chaparral, Mountain, and Tropical Biomes.

For areas that fall under a regulated setting through non-attainment and maintenance area designations, regional haze requirements, and their associated SIPs, the regulatory constraints of the location would be addressed in an action specific analysis. The impacts related to the emissions of HAPs would depend on the proximity of sensitive receptors in the impacted area. This type of analysis would require dispersion modeling or other risk calculation methods to evaluate the degree of the impact and identify appropriate mitigation measures.

If emissions are produced that are greater than the *de minimis* values, or if the emission increase would equal or exceed ten percent of the total emission inventory for the entire non-attainment area, then, a Conformity Determination under the Clean Air Act would be required. The *de minimis* thresholds in non-attainment areas are presented in Section 3 in Exhibit 3-3. A review of the state specific SIPs would be performed to identify whether the actions would equal or exceed 10 percent of the total emission inventory.

Airspace

The implementation of new operating parameters for existing support equipment would not impact airspace in any of the biomes considered. An increase in operations of support assets could affect the airspace of the biome where such activities would occur. The impacts on the airspace in the various biomes would be insignificant because all operations involving support equipment would be performed in accordance with existing airspace use requirements.

Biological Resources

Operational use changes could impact biological resources in the various biomes where such activities would occur. The impacts on biological resources would result from emissions of criteria pollutants and HAPs, equipment emitting EMR or radio frequencies, operations within sensitive environments (wetlands, critical habitat, essential fish habitat, wild and scenic rivers, or other protected natural resource areas), and debris from missile intercepts, catastrophic failure, or flight terminations. Methods employed to reduce impacts on natural resources including scheduling and duration considerations, as well as informal and formal consultations with regulatory agencies would be expected to reduce the potential for impact below significant levels. Should the impacts affect a threatened or an endangered species or its habitat, essential fish habitat, jurisdictional wetlands, or another regulated resource then in addition to analysis under NEPA and other applicable laws (Clean Water Act, Endangered Species Act), regulatory agency consultation would be required. The appropriate Federal agency must be consulted under Section 7 of the Endangered Species Act when site specific analysis indicates the continued existence of a threatened or endangered species is likely to be jeopardized.

Geology and Soils

In most biomes an operational use change would not impact geology or soils. However, in the Artic Tundra and Sub-Arctic Taiga Biomes, construction or modification activities have the potential to alter the condition of the permafrost that covers the biome. In addition, these biomes may be subject to earthquakes.

When appropriate, construction would incorporate seismic design parameters consistent with the critical nature of the facility and its geologic setting. In biomes with floodplains and the coastal environments, siting of facilities should consider the proximity to 100-year floodplains and maximum probable tsunami wave run-up areas.

Hazardous Materials and Hazardous Waste

An operational use change could result in an impact from the use of hazardous materials and the generation of hazardous waste, if such materials were used in the process. Such impacts could affect the biome where the action would occur. Should an operational use change result in new hazardous materials or hazardous waste, such items would be handled in accordance with specific protocols and appropriate regulations. Federal military ranges have established procedures in accordance with Federal regulations to ensure proper handling and use of these hazardous materials. These procedures would be reviewed to ensure that they address the hazardous materials that would be used. An evaluation of the potential impacts would occur if operational changes would utilize hazardous materials or generate hazardous waste not addressed in relevant specific protocols. All hazardous waste generated would be disposed of in accordance with

applicable laws and regulations. The personnel involved in hazardous material operations would be trained in the appropriate procedures, use appropriate personal protective clothing, and be up-to-date on any specialized training in hazardous material handling, spill containment and cleanup, or other hazardous material activities

Health and Safety

An operational use change would have the potential to impact health and safety. Impacts on health and safety are not associated with particular biomes; rather they are associated with the processes and activities that would be implemented under a specific action. The personnel who would operate equipment would be familiar with standard operating procedures and would receive specific equipment training as necessary. In addition to adhering to existing procedures, all activities would be performed in accordance with the health and safety requirements of the specific installation or test range, which are designed to protect public heath and safety.

Noise

Operational changes could impact ambient noise levels. Such impacts would affect the biome where the action would occur, and include new sources of noise or new operations that would alter the intensity, frequency, or duration of a noise-emitting source. The severity of such an impact would be related to the proximity of sensitive receptors to the noise source. Receptors include DoD workers, the general pubic, noise sensitive areas (housing developments, schools), and wildlife including critical habitat. An action- or site-specific study, in accordance with NEPA, would be performed for activities that may impact noise. Such a study would identify the receptors, quantify the impact, and recommend mitigation measures.

Transportation

Operational use changes could result in impacts to transportation; however, these impacts would not be significant. Mobile equipment would be used for a limited time during a test event, or would be used to transport supplies and components to and from various facilities. As indicated in Section 4.1.1.2, the use of support equipment during launch and post-launch activities (debris recovery) would not be expected to significantly impact transportation.

Water Resources

Because operational use changes of existing infrastructure would occur at existing facilities specifically designed for the support equipment in accordance with all relevant and applicable regulations, such activities would not impact water resources in any of the biomes. Operational use changes that would result in impacts to areas not specifically

designed for use of the support equipment could be subject to additional environmental review.

Orbital Debris

No impacts from orbital debris would occur as a result of an operational use change of support equipment.

Space-based equipment (satellites) could reenter the Earth's atmosphere due to failure, but would not likely result in significant impacts. Most objects break up and often vaporize under the intense aerodynamic forces and heating that occur during reentry. Most of the objects which reenter would fragment and burn in the upper atmosphere and would make only negligible changes in its chemical composition. Even if an object does survive reentry, only one third of the Earth is land area, and only a small portion of this land area is densely populated. The chance of hitting a populated land area upon reentry would be small. (SDIO, 1992)

4.1.1.9 Support Assets - Infrastructure

The following discussion of support asset infrastructure includes BMDS Test Bed infrastructure (test ranges and associated facilities), non-BMDS Test Bed Infrastructure (radar and tracking stations), and weapons basing platform infrastructure (missile silos) as discussed in Section 2.2.4.1 and Section 4.0. This equipment is part of the military services inventory and is used to support mission-related activities.

MDA reviewed the impact analyses and conclusions in previously prepared site-specific NEPA documentation, specifically for the use and modification of existing infrastructure, repair, maintenance, and sustainment. These activities have been analyzed in a number of previously prepared documents, including the *Ballistic Missile Defense Programmatic Environmental Impact Statement* (BMDO, 1994); *Ground-Based Midcourse Defense Initial Defense Operations Capability at Vandenberg Air Force Base Environmental Assessment* (MDA, 2003b); *Ground-Based Midcourse Defense Extended Test Range Environmental Impact Statement* (U.S. Army Space and Missile Defense Command, 2003); *National Missile Defense Deployment Environmental Impact Statement* (U.S. Army Space and Missile Defense Command, 2000); *Theater Missile Defense Extended Test Range Supplemental Environmental Impact Statement* (U.S. Army Space and Strategic Defense Command, 1998a); *Theater Missile Defense Extended Test Range Environmental Impact Statement* (U.S. Army Space and Strategic Defense Command, 1994a): *Evolved Expendable Launch Vehicle Program Environmental Impact Statement* (U.S. Department of the Air Force, 1998); *Point Mugu Environmental Impact Statement/Overseas Environmental Impact Statement* (U.S. Department of the Navy, 2002b); and *Pacific Missile Range Facility Enhanced Capability Environmental Impact*

Statement (U.S. Department of the Navy, 1998), and *Mobile Sensors Environmental Assessment (MDA, 2005)*.

These previous analyses show that potential impacts from infrastructure modification include construction-related impacts that could result from PM and construction equipment emissions. These emissions would be short-term, and would only affect those receptors close to construction areas. Activities that would continue in existing facilities at government and contractor installations would not result in any significant impacts. All activities would follow applicable regulations and established guidelines and management practices. Any increased water demands or demands on other utilities (electricity, natural gas, waste water disposal) that could be readily met by existing supply and treatment systems, groundwater withdrawals, or alternative sources, would not result in significant environmental impacts. (BMDO, 1994)

In many instances, use and modification or maintenance and sustainment of existing infrastructure is categorically excluded from further NEPA analysis. For example, per 32 CFR Part 651, Appendix B, construction of an addition to an existing structure or new construction on a previously undisturbed site is categorically excluded if the area to be disturbed has no more than five cumulative acres of new surface disturbance, and the construction does not individually or cumulatively have a significant effect on the human environment.

Previous analyses show that the impacts of such activities in support of the BMDS would not be significant because such activities would be performed in accordance with existing regulations. However, if proposed BMDS activities would result in major modification of existing infrastructure or major changes in use, site-specific NEPA analysis would be required. Additionally, changes in the level of human services used to support BMDS activities would be analyzed in site-specific NEPA analysis. In accordance with 40 CFR Part 1508.14, the site-specific NEPA analysis would address the socioeconomic impacts that are interrelated with impacts on the natural and physical environment.

The following sections present the impacts associated with site preparation and construction, including the modification of existing infrastructure, which are not sufficiently covered in previous NEPA analyses or categorically excluded.

Air Quality

The development of new or the major modification of existing infrastructure could impact air quality. Such impacts would affect the biome where the action would occur, and would result from site preparation and construction activities. Estimates of air quality impacts from construction are based on building square footage, acreage disturbed, and duration of construction, as well as general meteorological and soil information. Construction would require ground disturbances resulting in PM_{10} and

fugitive dust impacts. In 1995, EPA estimated that ground-disturbing activities cause the release of 1.08 metric tons (1.2 tons) of uncontrolled fugitive dust emissions per 0.4 hectare (1 acre) per month of ground-disturbing activity. (U.S. Army Space and Missile Defense Command, 2003) An estimated 50 percent of fugitive dust emissions consist of PM_{10}, though a more accurate percentage is based on the makeup of the local soil. (U.S. Army Space and Missile Defense Command, 2003) Standard fugitive dust reduction measures would be implemented when necessary. Water trucks might be used to dampen soil to minimize dust by releasing water or another biodegradable dust suppressant. The speed of construction vehicles would be restricted to limit soil separation into dust, and any soil stockpiled as fill material would be covered until use to prevent moisture evaporation and separation induced by wind. (MDA, 2003b)

The use of construction equipment would result in emissions of CO, NO_X, VOCs, and oxides of sulfur. Potential construction equipment emissions would be determined on a site-by-site basis by using emission factors from various sources including EPA. Proper tuning and preventive maintenance of construction vehicles would serve to minimize exhaust emissions and maximize vehicle performance. Construction would be conducted in accordance with all applicable laws and regulations. While the construction would cause an increase in air pollutants, it is assumed that the impact would be both temporary and localized. Once construction ceased, air quality would return to its former level.

Airspace

Site preparation and construction would not have any impact on airspace because all activities would take place on the ground and would not involve any closures or restrictions on airspace use. Modifications to infrastructure not previously addressed in NEPA analyses would not have any impact on airspace because the modifications would not result in any closures or restrictions on airspace use.

Biological Resources

Site preparation and construction could impact biological resources in the various biomes where such activities would occur. Vegetation, wildlife, and specific sensitive habitats could be affected based on the specific location of the development or modifications. The construction and expansion of buildings and roads could result in the clearing of vegetation and adverse impacts on wildlife near the activities. Site preparation activities may require pouring of pavement or spreading of gravel to facilitate mobility of the construction vehicles. Site preparation and construction activities that generate dust, irritable pollutants and noise, might temporarily disturb nearby wildlife, while permanent structures would result in the loss of habitat, displacement of wildlife, increased stress, and disruption of daily/seasonal behavior. (U.S. Army Space and Missile Defense Command, 2002d) Construction of infrastructure could lead to increased surface runoff. The combination of increased noise levels and human activity would likely displace some

small mammals and birds that forage, feed, nest, or have dens within a 15-meter (50-foot) radius of such activities. (U.S. Army Space and Missile Defense Command, 2002d) Whenever possible, construction and site preparation activities would occur on or near previously disturbed areas.

In Artic Tundra, Chaparral, and Tropical Biomes site preparation and installation activities for underground cable could impact species that rely on the shore environment including species of pinnipeds, shorebirds, waterbirds, otters and whales, and sea turtles. The installation of marine underground cable through near shore areas and through shoreline and tidal areas could disturb the habitats that these species depend on.

Pinnipeds and shorebirds are easily startled by noise and movement. (U.S. Army Space and Missile Defense Command, 2003) Site preparation and construction activities could cause a range of behavioral responses from heightened alertness to abandonment of favorable habitat areas. (U.S. Army Space and Missile Defense Command, 2003) It may also be possible for site preparation and construction noise to lead to nest abandonment or changes in migration routes. The severity of the response would depend on the intensity (noise level, area of the disturbance) of the installation project, the proximity to the pinniped and shorebird habitats, and the sensitivity of the species. Site-specific analyses would more accurately assess the potential impacts of the proposed activities on biological resources.

Shorebirds are very sensitive to noise during the nesting season. (U.S. Army Space and Strategic Defense Command, 1998a) The flushing of shorebirds from nests could result in the exposure of eggs to excess cold/heat and to predation.

Construction activities would be planned and sited to avoid regulated habitats (jurisdictional wetlands, critical habitat, or essential fish habitat). Should the impacts affect a threatened or an endangered species or its habitat, essential fish habitat, jurisdictional wetlands, or another regulated resource then in addition to analysis under NEPA, compliance with other laws (e.g., Clean Water Act, Endangered Species Act, Marine Mammal Protection Act, Migratory Bird Treaty Act, and Bald and Golden Eagle Protection Act), and regulatory agency consultation would be required. The appropriate Federal agency must be consulted under Section 7 of the Endangered Species Act when site specific analysis indicates the continued existence of a threatened or endangered species is likely to be jeopardized.

Environmentally sensitive habitats could be impacted by site preparation and construction activities for underground cable. Trenching through coral reef areas would adversely impact the reef. Coral reefs are slow developing habitats that are very sensitive to changes in water quality. The trenching activity would disturb seafloor sediment and would temporarily increase the turbidity of the water column. This would lower the solar light penetration that the reefs depend on for growth and energy. (University of the

Virgin Islands, 2003) In addition, the trenching activities would break up existing reef. Studies have shown that coral reefs are very sensitive to physical disturbances. Reefs that have been physically damaged can be more susceptible to disease. (University of the Virgin Islands, 2003) Underground cable site preparation and construction activities would comply with EO 13089 and would be avoided to the extent possible in coral reef areas.

The marine underground cable installation activities could startle and temporarily displace whales and sea otters. However, these species would likely return once the installation is complete. Installation activities that occur in freshwater and tidal streams could cause siltation and disturbance of maturation and feeding habitats for some species of fish. (U.S. Army Space and Strategic Defense Command, 1994a) Site-specific studies should analyze the potential impacts of the proposed activities on the biological resources of the affected environment.

Studies have shown that artificial light can affect sea turtle behavior. (U.S. Army Space and Strategic Defense Command, 1998a) Artificial light associated with construction sites could confuse nesting sea turtles causing abandonment of nesting sites. Artificial lights could also confuse hatchling turtles by causing them to move in circles and reducing their chances of making it safely to the ocean. (U.S. Army Space and Strategic Defense Command, 1998a) Trenching and backfilling in sea turtle nesting areas could disturb buried nests or cover the nests with a sand layer too deep for the hatchlings to escape. Because sea turtle and shorebird nesting is a seasonal process, construction activities could be coordinated to avoid nesting seasons. Site-specific analyses would more accurately assess the potential impacts of the proposed activities on biological resources.

Geology and Soils

Typical construction activities that could adversely affect local geology and soils include cut-and-fill operations, paving operations, compaction, mixing, grading, and general soil erosion. Exposed soils become dry and porous and shift easily resulting in increased erosion rates. Paving operations would degrade the quality of the soil as it mixes with tar and reduces permeable surfaces. Best Management Practices[53] would be implemented to minimize negative short-term effects of clearing and grading activities during site preparation, as well as excavations and grading for connecting infrastructure, roadways and parking. Any construction activities greater than five-acres would be required to obtain an NPDES storm water run-off permit, which typically specifies the Best Management Practices for the entire construction site. Except for localized soil compaction in the construction area, long-term impacts to the soils resulting from

---

[53] A best management practice is a business function, process, or system considered superior to all other known methods, that improves performance and efficiency in a specific area. (Office of the Secretary of Defense Comptroller iCenter, 2004)

construction would not be anticipated. (U.S. Army Space and Missile Defense Command, 2003)

Site preparation and construction could impact the geology and soils of the Artic Tundra and Sub-Arctic Taiga Biomes. Such impacts would be related to activities that alter the condition of the permafrost that covers the biome.

Whenever possible, construction and site preparation activities would occur on or near previously disturbed areas to limit or reduce disturbance of undisturbed areas. Construction would incorporate seismic design parameters consistent with the critical nature of the facility and its geologic setting. In biomes with floodplains and the coastal biomes, facilities should be constructed outside of existing 100-year floodplains and beyond established limits for tsunami wave run-up for a maximum probable tsunami event. (U.S. Army Space and Missile Defense Command, 2003)

Hazardous Materials and Hazardous Waste

Site preparation and construction and development could result in an impact from the use of hazardous materials and the generation of hazardous waste. Such impacts would affect the biome where the action would occur. Based on the type of infrastructure the potential hazardous wastes that would be generated during construction and site preparation include solvents, cutting fluids, acetylene, and various paint products, used acetone, motor fuels, heating fuels, waste oils, hydraulic fluids, used batteries, and waste antifreeze. Small quantities of solvents are typically used for degreasing or other cleaning activities. Residual solvents would be disposed of as hazardous waste along with contaminated materials (e.g., rags). Hazardous waste disposal would take place at permitted sites equipped to handle the safe and proper disposal of such materials.

A Pollution Prevention Plan would be implemented for new or major modification to existing infrastructure. This plan would control and reduce the use of hazardous materials at the site. (U.S. Army Space and Missile Defense Command, 2002d) In addition, the program would comply with any existing base Pollution Prevention Plan. Program personnel would continue to update the system-wide Pollution Prevention Plan, which would outline strategies to minimize the use of hazardous materials over the life cycle of the facilities.

Renovation and site preparation activities may generate wastes that include asbestos-containing material and lead-based paints. Prior to any existing building modification or demolition, surveys would be conducted to determine if these materials are present in the modification area. A licensed asbestos abatement contractor, in accordance with state and Federal regulations, would perform renovations in these instances. All removed asbestos would be disposed of in a solid-waste landfill designed to receive asbestos-containing material. Management and abatement of asbestos and lead-based paint at

selected sites would be compliant with management plans such as a Lead-Based Paint Management Plan, an Asbestos Management Plan, an Asbestos Operating Plan, as well as the applicable legal requirements. (U.S. Army Space and Missile Defense Command, 2003)

Health and Safety

Site preparation and construction could impact health and safety. Impacts on health and safety are not associated with particular biomes, rather are associated with the processes and activities that would be implemented under a specific action. Potential health and safety hazards from site preparation and construction activities include dust/particulate inhalation, improper chemical handling, and improper use of machinery. General safety procedures would be followed to protect construction workers, base personnel, and the general public during site preparation and construction activities. No impacts to human health and safety from site preparation and construction activities would be expected, if all applicable legal requirements are met.

Construction activities would produce physical hazards such as noise, electrical, heavy-moving equipment and machinery, welding, and earth moving and digging activities. Health and safety procedures would be compliant with appropriate management plans and applicable regulations. Any waste would be collected and segregated as non-hazardous, hazardous, and possibly special wastes for proper disposal in accordance with applicable legal requirements.

The design of new facilities or the modification of exiting facilities would incorporate measures to minimize the potential for and impact of health and safety related accidents. Operating procedures and training would be instituted to minimize the potential for and impact of releases of hazardous materials. Specific health and safety plans would be developed including evacuation plans, and notification of local and offsite emergency response as required.

Noise

Site preparation and construction and development of new or the major modification of existing infrastructure could impact ambient noise levels. Such impacts would affect the biome where the action would occur, and would be related to construction activities or new operations that would alter the intensity, frequency, or duration of a noise emitting source, and would depend upon the sensitivity of the receptor to the sound generated. Receptors include workers, wildlife, and the public in the proximity of the noise source. Site preparation and construction activities would be comparable to common construction activities. The amount of noise generated would depend upon the amount and type of construction being done. Construction on existing facilities would likely be minor; construction of new infrastructure could result in larger impacts. Personnel that may be

exposed to loud noises would be required to wear hearing protection, such as earplugs and earmuffs, which would reduce the noise levels to prescribed health and safety levels. An action or site-specific study would be performed for activities that may increase noise levels. Such a study would identify sensitive receptors and their locations, quantify the impact, and recommend mitigation measures.

Transportation

Site preparation and construction activities may require the use of heavy machinery the transportation of which could cause changes in the amount of congestion on the existing road network. In addition, an influx of construction workers may change the level of demand for access to the existing roadways. In general, these activities would not be expected to cause a significant impact on transportation. However, if these changes in demand and congestion demonstrate the potential for significant impact, site specific analyses would be prepared.

Water Resources

Site preparation and construction could impact water resources by increasing operations resulting in a discharge of wastewater. Modifications or construction activities would follow site-specific protocols for storm water and ground water pollution prevention, and would require application for appropriate permits and development of pollution prevention plans for protection of water resources on- and off-site. For new installations, site-specific documentation would be required to determine potential effects of construction and operation activities on surface water, ground water, and floodplains. The impacts on water resources would be analyzed in accordance with NEPA and other appropriate regulations, including the Clean Water Act and any applicable international or foreign legal requirements for activities outside of the U.S.

Orbital Debris

No impacts from orbital debris would occur as a result of site preparation and construction.

4.1.1.10 Support Assets - Test Assets

The following discussion of support asset test assets include assets of the BMDS Test Bed (test sensors and communications) and assets that are used to support the BMDS Test Bed (targets, countermeasures, and simulants) as discussed in Section 2.2.4.1 and Section 4.0. This equipment is part of the military services inventory and is used to support mission-related activities.

MDA reviewed the impact analyses and conclusions in previously prepared site-specific NEPA documentation, specifically for the development and use of test assets. These activities have been analyzed in a number of previously prepared documents, including the *Ballistic Missile Defense Programmatic Environmental Impact Statement* (BMDO, 1994); *Ground-Based Midcourse Defense Initial Defense Operations Capability at Vandenberg Air Force Base Environmental Assessment* (MDA, 2003b); *Ground-Based Midcourse Defense Extended Test Range Environmental Impact Statement* (U.S. Army Space and Missile Defense Command, 2003); *National Missile Defense Deployment Environmental Impact Statement* (U.S. Army Space and Missile Defense Command, 2000); *Theater Missile Defense Extended Test Range Supplemental Environmental Impact Statement* (U.S. Army Space and Strategic Defense Command, 1998a); *Theater Missile Defense Extended Test Range Environmental Impact Statement* (U.S. Army Space and Strategic Defense Command, 1994a): *Evolved Expendable Launch Vehicle Program Environmental Impact Statement* (U.S. Department of the Air Force, 1998); *Point Mugu Environmental Impact Statement/Overseas Environmental Impact Statement* (U.S. Department of the Navy, 2002b); and *Pacific Missile Range Facility Enhanced Capability Environmental Impact Statement* (U.S. Department of the Navy, 1998).

MDA also reviewed existing categorical exclusions to determine which activities associated with the development and use of test assets are categorically excluded from further NEPA analysis.

The activities previously analyzed and those that are categorically excluded include the development, manufacturing, and assembly of components and component prototypes at existing DoD and non-DoD (contractor) facilities.

For example, the *Theater High Altitude Area Defense Initial Development Program Environmental Assessment* (U.S. Army Space and Strategic Defense Command, 1994c) found that all manufacturing and engineering activities would be accomplished in existing facilities and would use personnel routinely engaged in these types of activities. The facilities and personnel utilized would operate at levels and intensities similar to current conditions, which would result in no significant impacts. In addition, the EA found that manufacturing and engineering various missile components would involve the use of various hazardous materials. Because the facilities would comply with the CCR, Title 22, Division 4, Environmental Health; Title 40 CFR, Parts 260-280, and the RCRA, as well as specific facility guidelines that describe procedures for items such as correct storage, labeling, and transportation of hazardous waste, such activities would be not significant.

Similarly, because the manufacturing and assembly of the BMDS components would occur at existing facilities, would follow established standard operating procedures to protect worker and public safety, and would be performed in accordance with all appropriate and relevant laws and regulations, the impacts associated with manufacturing

would not be significant. However, should an activity require new or major modification to an existing DoD-owned or operated manufacturing facility, or require the preparation of new assembly standard operating procedures, action-specific NEPA analysis would be conducted.

The use of test assets in various configurations has been considered in previous NEPA analyses. Most of this equipment is sensor, tracking (optical, laser, and radar systems), and communications systems. The use of such equipment is both installation- and scenario-specific. Previous analyses have shown that impacts associated with the use of support equipment for test assets would not be significant.

The use of targets and their boosters, target test objects, simulants and countermeasures at some specific locations has been considered in previous NEPA analyses. For example, the *Ground-Based Midcourse Defense Extended Test Range Environmental Impact Statement* (U.S. Army Space and Missile Defense Command, 2003), shows that the Peacekeeper target missile would contain less solid rocket fuel and would produce lower exhaust emissions that existing target missiles. In addition, modeling of target missiles to include dual launches demonstrated that the level of HCl emitted would be below the 1-hour Air Force standard, but would exceed the peak HCl standard for a short duration. The emission levels for both CO and Al_2O_3 were determined to be within NAAQS and California AAQS; therefore, the nominal launch of a single Peacekeeper target missile is anticipated to remain within NAAQS, California AAQS, and Air Force Standards. Previous analyses show that the impacts associated with the use of targets and their boosters for activities associated with the proposed BMDS would have no significant impacts.

The use of drones as targets has been considered in previous NEPA analyses and has not been found to result in significant impacts. Drones are used to mimic the heat and radar returns of missiles and aircraft, and can use various countermeasures to deceive interceptors. The potential for impacts from the use of drones is influenced by the specific flight pattern to be flown and intercept altitude, if appropriate. Site specific analysis including debris analysis might be required for future proposed actions using drones.

The development and use of individual test assets (e.g., sensors, targets, and drones) have been analyzed in site-specific NEPA documents, which found no significant impacts from such activities. The development and use of those test assets as defined in the previous site-specific NEPA documents would not result in a significant impact. The combined impact associated with test assets and the other BMDS components was analyzed in Section 4.1.2, Test Integration. The following sections present the impacts associated with the use of simulants and countermeasures.

Air Quality

The development and use of simulants, countermeasures, and drones could impact air quality in the biome where the action would occur. The prelaunch activities where the simulants, countermeasures, and drones are assembled and prepared for use would result in the emissions of Federal or state-listed criteria pollutants, as well as potential HAP emissions. The HAPs that may be released would depend on the chemical composition of the simulant or countermeasure, or the materials associated with the drones. The use of simulants, countermeasures, and drones during test events would result in emissions to the air; however, based on the parameters of the specific test, the emissions may be at an elevation above 914 meters (3,000 feet) and would not affect ground level air quality. Based on the chemical composition and volume of the simulant, or the composition and volume of volatile substances in the countermeasure component or drone, the emissions above 914 meters (3,000 feet) may impact air quality in terms of ozone depletion (particularly in the upper troposphere and stratosphere), acid rain, and global warming. Existing impact analyses prepared in accordance with NEPA and standard operating procedures would be reviewed to ensure that the activities would not result in a significant impact. Site-specific environmental analysis would be completed to evaluate potentially significant impacts.

Airspace

The use of delivery systems (boosters) for the simulants and countermeasures, as well as the simulants and countermeasures themselves could impact airspace of the biome where the action would occur. The operating altitudes, lateral orientation, specific type of airspace, and the region of influence are the parameters of specific test scenarios that influence the degree of the impact on airspace. The use of simulants and countermeasures may increase the duration and severity of impact on a particular airspace. The impacts of specific simulants and countermeasures on airspace would be reviewed in accordance with NEPA.

Biological Resources

The development and use of simulants and countermeasures could impact biological resources of the biome where the action would occur. Should the impacts affect a threatened or endangered species or its habitat, essential fish habitat, or jurisdictional wetlands, or another regulated resource then in addition to analysis under NEPA, compliance with other applicable laws (e.g., Clean Water Act, Endangered Species Act, Marine Mammal Protection Act, Migratory Bird Treaty Act, and Bald and Golden Eagle Protection Act), as well as regulatory agency consultation could be required.

Geology and Soils

The development and use of simulants and countermeasures would not impact geology; however, such activities could impact soils in the biome where the action would occur. The impact would result from the deposition of the simulants or countermeasures on the soil. The severity of the impact would be based on the composition of the simulant or countermeasure. The impacts related to the use of new simulants or countermeasures would be evaluated as necessary in accordance with NEPA.

Hazardous Materials and Hazardous Waste

The development and use of simulants and countermeasures could result in an impact from the use of hazardous materials and the generation of hazardous waste. A wide variety of hazardous materials may be used in the development of simulants and countermeasures including solvents, and toxic metals and substances. No radioactive materials would be used in the development and use of simulants and countermeasures. The development and use of specific simulants and countermeasures would include a life cycle analysis of potential impacts, including specific decommissioning activities for any hazardous materials. Hazardous materials or hazardous waste associated with the use of a simulant or countermeasure would be handled in accordance with installation and range specific protocols and appropriate regulations. Federal military ranges have established procedures in accordance with Federal regulations to ensure proper handling and use of these hazardous materials. These procedures would be reviewed to ensure that they address the appropriate hazardous materials. An evaluation of the potential impacts in accordance with NEPA and other relevant regulations would occur if the use of a simulant or countermeasure would utilize hazardous materials or generate hazardous waste not addressed in installation specific protocols. All hazardous waste generated would be disposed of in accordance with appropriate state and Federal regulations. The personnel involved in hazardous material operations would be trained in the appropriate procedures and would use appropriate personal protective clothing and would be up-to-date on any specialized training in hazardous material handling, spill containment and cleanup, or other hazardous material activities.

Health and Safety

The development and use of simulants and countermeasures could impact health and safety. Impacts on health and safety are not associated with particular biomes; rather they are associated with the processes and activities that would be implemented under a specific action. Health and safety impacts would be commensurate with the chemical composition of the simulant and the operating parameters involved with the use of simulants and countermeasures. New standard operating procedures that address safe handling and operational requirements to protect public health and safety would be developed for new or modified simulants and countermeasures. Such plans would

address health and safety issues for general operation and handling, as well as health and safety operations for system and operational testing and failures. The personnel who would operate and handle such equipment would be familiar with the standard operating procedures and would receive specific training as necessary. These actions would be performed in accordance with health and safety requirements of the specific installation or test range, which are specifically designed to protect public heath and safety.

Noise

The development and use of simulants or countermeasures would not impact noise within any biomes because these activities do not generate noise. The noise associated with the delivery system (i.e., booster) of a simulant or countermeasure is presented in Weapons – Interceptors.

Transportation

The development and the use of simulants would not impact transportation. As indicated in Section 4.1.1.2, short-term road closures along launch trajectories, the issuance of NOTAMs and NOTMARs to notify pilots and mariners of area closures, and debris recovery activities would not be expected to impact transportation.

Water Resources

The development and use of simulants and countermeasures could impact water resources in the biome where the action would occur. The severity of the impacts would depend on the chemical composition of the simulant or countermeasure. Impacts would occur from the deposition of simulants and countermeasures on surface waters, or from simulants migrating through soils to ground water. The disposal of simulants or countermeasures would follow appropriate protocols for the composition of the simulants and countermeasures. Prior to using simulants or countermeasures that may impact water resources, the impacts related to the specific chemical composition and operational testing environment would be analyzed in accordance with NEPA. Compliance with Federal and state regulations also would be required.

Orbital Debris

If countermeasures are used and remain on-orbit, they have the potential to disrupt or damage other space-based assets (e.g., communication satellites). However, orbiting objects lose energy through friction with the upper atmosphere and various other orbit perturbing forces. Over time, objects including countermeasures, may drop into progressively lower orbits and may eventually fall to Earth. As the object's orbital trajectory draws closer to Earth, it speeds up and outpaces objects in higher orbits. Once

the object enters the measurable atmosphere, atmospheric drag will slow it down rapidly and cause it either to burn up or deorbit and fall to Earth.

4.1.2 Test Integration

Test integration considers the range of integrated testing activities the BMDS proposes to implement to transition from the testing of individual components to the evaluation of how they will work together and perform as the BMDS. Modeling, simulation, and analysis; MDIE; and integrated missile defense wargames are virtual tests (modeling and computational analyses) or software compatibility and communication tests that would be conducted within existing laboratory or test facilities. Because of the nature of these tests, no significant impacts would occur in any biome. However, activities associated with GTs and SIFTs would have the potential for environmental impacts.

GTs test components for interoperability. Such tests would assess and evaluate the C2BMC integration of the various components as well as the assimilation and use of the various sensors tracking system data. No laser weapons would be activated and no interceptors would be launched during GTs. To conduct these tests, multiple sensors and C2BMC components could be used from land-, air-, sea-, and space-based operating environments that would coordinate the control and transfer of information between weapons based on land, sea, and in the air. These sensors and C2BMC components could be activated from within the same biome or across several biomes.

For purposes of this analysis, two representative scenarios that could be used for SIFTs were considered. These two scenarios involve similar activities (launches of targets, use of multiple sensors, and use of land-, sea-, and air-based weapons); however, they differ in number of target launches and number of weapons used. Both scenarios may be used to support the proposed BMDS and are analyzed in this PEIS.

SIFT Scenario 1 – Single Weapon with Intercept represents the simplest SIFT and would include the launch of a single target and use of a single weapon component to intercept the target. This scenario would use multiple sensors and C2BMC components as described for GTs. Under SIFT Scenario 1, the launch of the target and the activation of a laser or launch of an interceptor may occur within the same biome (e.g., all within the Desert Biome) or may involve multiple biomes (e.g., target launch from the Tropical Biome and laser activation or interceptor launch in the BOA). As BMDS capabilities are proven, a second SIFT Scenario is envisioned that would build upon SIFT Scenario 1.

SIFT Scenario 2 – Multiple Weapons with Multiple Intercepts would include the launch of up to two targets. For each target launch, more than one weapon component (land-, sea-, or air-based) would be able to engage or "take a shot" at the target. Dual-target or interceptor launches would occur within seconds or minutes of each other. As with SIFT Scenario 1, numerous sensor components also would acquire the target and relay tracking

data. Under this test scenario, the two targets may be launched from one biome and the weapons may be activated or launched from the same or different biomes.

Environmental Consequences

Component testing would continue to occur under Alternative 1. These component tests would be conducted in addition to the proposed System Integration Tests. SIFTs would generally be designed around planned component flight tests. However, MDA may schedule additional tests that are not part of previously planned flight tests. Therefore, the total number of target and interceptor launches and laser, sensor, and C2BMC activation events would increase when compared to the No Action Alternative. This would increase the total number of tests, and thus the magnitude of environmental impacts.

The environmental consequences associated with the use of BMDS components under Alternative 1 are analyzed in Section 4.1. Impacts from activities that are discussed earlier in this PEIS will not be discussed in this section. Therefore, the analysis of System Integration Tests will focus on those environmental impacts that are unique to these types of tests. For this programmatic analysis, a qualitative impact assessment was completed for each resource area because specific System Integration Test parameters have not been developed that would provide quantitative values.

The activities associated with each type of System Integration Test analyzed in this PEIS include

- **Integrated GTs**. The activation of multiple sensors and C2BMC components, and passive activation of weapons (e.g., powering the tracking and communication aspects of the weapons system but not firing the weapon) within the same biome or across several biomes, which would coordinate the control and transfer of information between land-, sea-, and air-based weapons.

- **SIFT Scenario 1 – Single Weapon with Intercept**. The activation of multiple sensors and C2BMC components within the same biome or across several biomes coupled with the launch of one target and the activation of a laser or launch of an interceptor, and the debris from an intercept. Because the impacts associated with the use of multiple sensors and C2BMC components is discussed for GTs, this portion of the impacts analysis will not be repeated for this scenario.

- **SIFT Scenario 2 – Multiple Weapons with Multiple Intercepts**. The activation of multiple sensors and C2BMC components within the same biome or across several biomes coupled with the launch of up to two targets from the same biome or different biomes, the activation or launch of multiple weapons in the same biome or multiple biomes, and the debris from each intercept. Because the impacts associated with the

use of multiple sensors and C2BMC components are discussed for GTs, this portion of the impacts analysis will not be repeated for this scenario.

4.1.2.1 Air Quality

Integrated GTs

The emissions from generators required to power sensor and C2BMC systems could impact air quality. However, these generators would only be operated for a short time and the emissions associated with the activation of one generator would be a small fraction of *de minimis* thresholds. Activating multiple generators in a single biome or across multiple biomes would not have a significant impact on air quality.

The activation of radars, infrared, and optical sensors would not impact air quality. Leaks of inert gases, such as helium, N_2, and CO_2, from gas propellant laser sensors could occur; however, a leak of these gases to the atmosphere would be insignificant relative to ambient oxygen concentrations. There are no air emissions associated with the activation of solid-state lasers; therefore, no impacts to air quality would be expected. An increase in the number of laser sensors activated during GTs would not have a significant impact on air quality regardless of whether the sensors were located in the same or multiple biomes.

SIFT Scenario 1 – Single Weapon with Intercept

In addition to the impacts presented under GTs, the emissions from SIFT Scenario 1 would include emissions from activation of lasers and launches. The primary exhaust products of boosters and lasers would be as described for weapons components. An intercept would result in the release of gases and PM.

For a target launch and the activation of a laser or launch of an interceptor occurring in the same biome, the emissions from laser activation and launches combined with the release of gases and particulates from an intercept could impact air quality. Exhibit 4-11 shows the combined emission products from the launch of a representative target and interceptor within the same biome. Exhibit 4-12 shows the emission products from the launch of a representative target and the activation of a laser within the same biome. Emissions from launch activities and laser activation would not be expected to result in significant impacts to air quality. EPA uses six criteria pollutants as indicators of air quality, including ozone, CO, NO_2, SO_2, PM, and lead, and has established a maximum concentration for each, above which adverse effects on human health may occur. Of these pollutants, only CO is emitted during the launch of targets and the launch or firing of weapons. The *de minimis* level for CO is 91 metric tons (100 tons) per year. As shown in Exhibits 4-11 and 4-12, CO levels for the launch of a target and a launch of an interceptor would be only three percent of the *de minimis* level. The CO levels for the

launch of a target and the activation of a laser also would be less than two percent of the *de minimis* level. The magnitude of potential impacts from other emissions from launch and laser activation would depend on the biome in which the activities took place and would be analyzed in site-specific analyses. Impacts to air quality from laser activation and launches occurring in different biomes would not have the additive impacts of activities occurring within the same biome.

Exhibit 4-11. Emission Products from Launches of Representative Targets and Interceptors in metric tons (tons)

Emission Product	Target	Interceptor	Total
Al_2O_3	2.30 (2.54)	3.01 (3.32)	5.31 (5.85)
CO	1.75 (1.93)	0.98 (1.08)	2.73 (3.01)
HCl	1.73 (1.91)	1.77 (1.95)	3.50 (3.86)
N_2	0.68 (0.75)	5.77 (6.36)	6.45 (7.11)
H_2O	0.92 (1.02)	1.93 (2.13)	2.85 (3.15)
H_2	0.16 (0.17)	0.00 (0.00)	0.16 (0.17)
CO_2	0.34 (0.37)	1.47 (1.62)	1.81 (1.99)
Other	0.00 (0.00)	0.16 (0.18)	0.16 (0.18)

Exhibit 4-12. Emission Products from Launches of Representative Targets and Lasers in kilograms (pounds)

Emission Product	Target	Laser	Total	Total metric tons (tons)
Al_2O_3	2,300 (5,060)	-	2,300 (5,060)	2.30 (2.54)
CO	1,747 (3,846)	-	1,747 (3,846)	1.75 (1.93)
HCl	1,733 (3,815)	-	1,733 (3,815)	1.73 (1.91)
N_2	680 (1,497)	108 (238)	788 (1735)	0.79 (0.87)
H_2O	924 (2,033)	540 (1,190)	1464 (3223)	1.46 (1.61)
H_2	156 (344)	23 (51)	179 (395)	0.18 (0.20)
CO_2	336 (739)	396 (873)	732 (1612)	0.73 (0.81)
Oxygen	-	270 (595)	270 (595)	0.27 (0.30)
Cl	-	36 (79)	36 (79)	0.04 (0.04)
Ammonia	-	81 (179)	81 (179)	0.08 (0.09)
Iodine	-	13 (29)	13 (29)	0.01 (0.01)

Source: U.S. Army Space and Strategic Defense Command, 1993c; Dailey, 1993 as referenced in U.S. Army Space and Strategic Defense Command, 1994d and U.S. Department of the Air Force, 1997b

SIFT Scenario 2- Multiple Weapons with Multiple Intercepts

In addition to the impacts presented under SIFT Scenario 1, the emissions from launching any two targets (liquid- or solid-propellant) from the same location at the same time would not be expected to result in significant impacts to air quality, provided that such an activity is within the operating parameters of the launch facility or range. The launch or activation of multiple weapons and use of additional support equipment would result in a localized increase in emissions. The concentration of the localized emissions and the subsequent severity of the impact would vary based on the number of launches or activations and support equipment, the proximity (both geographically and in time) of each launch or activation and operation of support equipment, and the specific location of such activities within a biome. The combined impacts of all the emissions associated with SIFT Scenario 2 (emissions from support equipment, launches, laser activations, and debris from intercepts) might result in significant impacts to air quality. Site-specific environmental analysis would be completed to evaluate potentially significant impacts.

4.1.2.2 Airspace

Integrated GTs

EMR and other radio frequency transmissions associated with radar sensors and C2BMC equipment activated during GTs could potentially impact airspace operations by interfering with communication and navigation equipment. Coordination with the appropriate FAA ARTCC, relevant military installations, and relevant foreign countries with jurisdiction over affected airspace would minimize the potential for impact from these tests.

In addition, laser sensors have the potential to cause eye damage to aircraft pilots. All laser sensors would be operated according to appropriate range safety regulations. An increase in the number of laser sensors activated during GTs would not be expected to significantly impact airspace.

SIFT Scenario 1 - Single Weapon with Intercept

In addition to the impacts presented under GTs, the impacts associated with airspace from SIFT Scenario 1 would include the additional restricted airspace associated with launches and the activation of lasers. Launches of targets and the activation or launch of a weapon, and impact of the target and interceptor would occur in designated areas of cleared airspace. Close coordination with the appropriate FAA ARTCC, relevant military installations, and foreign countries with jurisdiction for airspace management would minimize the potential for any adverse impacts on airspace use and scheduling. In addition, before conducting an operation that is potentially hazardous to non-participating aircraft, NOTAMs would be issued.

Retrieval of debris on land would occur within the boundaries of the designated impact area; therefore, debris retrieval would have no impact on navigable airspace or airborne activities outside the restricted airspace complex. It is not anticipated that debris falling into the BOA would be retrieved.

SIFT Scenario 2 – Multiple Weapons with Multiple Intercepts

In addition to the impacts presented under SIFT Scenario 1, the additional impacts to airspace under SIFT Scenario 2 would result from a larger portion of cleared airspace required to support the specific SIFT, the increased duration of the test, the additional debris areas associated with two targets and multiple intercept attempts, and increased operation of support equipment, which could result in an increase in the disruption of commercial and civilian air travel and operations. Close coordination with the appropriate FAA ARTCC, military installations, and relevant foreign countries with jurisdiction over affected airspace would reduce the potential impacts to airspace. Upon completion of such coordination for each test, there would be no significant impacts to airspace.

4.1.2.3 Biological Resources

Integrated GTs

Impacts to biological resources resulting from GTs would include EMR emissions from radar sensors and laser beams from laser sensors. The size, motion, and orientation of the beams would limit the beam exposure time on biological resources. An increase in the number of radar sensors operating within a biome would increase the risks to biological resources, but the impacts would be insignificant.

SIFT Scenario 1 – Single Weapon with Intercept

In addition to the impacts presented under GTs, the impacts from SIFT Scenario 1 would include the emissions associated with activation of lasers, including CO_2, ammonia, and chlorine. Such impacts are considered to be minor as the laser would be operated for a few seconds per launch, and would not emit large quantities of gases. Potential impacts from launches include emissions, deposition of hazardous materials, debris associated with intercepts, and noise associated with launch and flight. Impacts to biological resources associated with SIFT Scenario 1 activities would result primarily from the noise associated with launch and intercept. Sonic booms may create startle responses in some animals. Debris from the intercept could directly hit an animal. Coordination and consultation with appropriate regulatory agencies, as well as adherence to appropriate and relevant international treaties, would be required to address any potentially significant impacts on biological resources. Impacts to biological resources would depend on the

biome in which the launch and intercept took place. The potential for and extent of impact would need to be examined in site-specific environmental analysis.

SIFT Scenario 2 – Multiple Weapons with Multiple Intercepts

In addition to the impacts presented under SIFT Scenario 1, the environmental impacts to biological resources under SIFT Scenario 2 are related to the biome and the threatened and endangered species, the unique or sensitive environments, and the migratory, breeding, and feeding activities that occur in the biome, which would be affected by such activities. Site-specific environmental analysis would be completed to evaluate potentially significant impacts.

4.1.2.4 Geology and Soils

Integrated GTs

Impacts to geology and soils as a result of GTs would be limited to fuel spills associated with generators. Appropriate control, handling, and clean up procedures would be in place for any hazardous material spills or leaks. An increase in the number of sensors or C2BMC systems tested within a biome would not significantly increase the impacts to geology and soils.

SIFT Scenario 1- Single Weapon with Intercept

In addition to the impacts presented under GTs, the impacts from SIFT Scenario 1 would include increased soil acidity from the emission of small amounts of chlorine if the laser is activated in a humid biome. Similarly, HCl emitted primarily from launch of solid propellant boosters could be deposited on the soil in the form of acid rain and result in increased soil acidity.

Impacts to geology and soils also may result from the emissions and subsequent deposition of PM and any simulant used in the target. A target launch and the activation or launch of a weapon would not result in a significant impact to geology and soils.

SIFT Scenario 2 – Multiple Weapons with Multiple Intercepts

The activities performed under SIFT Scenario 2 would not impact geology. In addition to the impacts presented under SIFT Scenario 1, the environmental impacts to soils under SIFT Scenario 2 would be related to the biome, the characteristics and condition of the soil, and the type and amount of material that would be deposited on the soil during a test event. Site-specific environmental analysis would be completed to evaluate potentially significant impacts.

4.1.2.5 Hazardous Materials and Hazardous Waste

Integrated GTs

GTs would involve an increase in the volume of hazardous materials and hazardous wastes used and generated by the testing of sensors and C2BMC systems. However, hazardous materials and hazardous waste would be handled in accordance with all applicable regulations, and each test location would have an SPCC plan in place to handle any spills or leaks of hazardous materials. An increase in the use of sensors and communication systems in a biome would not result in significant impacts from hazardous materials and hazardous waste.

SIFT Scenario 1 – Single Weapon with Intercept

SIFT Scenario 1 would potentially increase the impacts from hazardous materials and hazardous waste. The impacts from laser activation would include the production of spent laser chemicals, which would be neutralized and treated as waste. Potential impacts from launches include fueling procedures (if applicable) and debris disposal. Appropriate waste management and disposal procedures would be in place to safely manage these substances in accordance with applicable regulations.

For a target launch and the activation of a laser or launch of an interceptor, impacts from hazardous materials and hazardous waste would not result in a significant impact. Applicable regulations and procedures would be followed and would prevent impacts from management and disposal of hazardous materials or hazardous waste. If appropriate, debris from launches would be handled in accordance with approved disposal requirements.

SIFT Scenario 2 – Multiple Weapons with Multiple Intercepts

The activities under SIFT Scenario 2 would use more hazardous materials and would generate more hazardous waste than those under SIFT Scenario 1. The increased use and generation of hazardous materials and hazardous waste would not result in a significant impact. Hazardous materials and hazardous waste including debris (if appropriate) would be handled in accordance with approved disposal requirements.

4.1.2.6 Health and Safety

Integrated GTs

Operation of multiple sensors and C2BMC systems during GTs would increase potential risks to health and safety. All health and safety procedures would be followed in the operation of the sensors and C2BMC systems. Appropriate safety exclusion zones,

personnel exclusion zones, and EMR hazard zones would be established prior to testing. All participating personnel would be trained and certified in the risks associated with testing and operation of sensors and C2BMC systems. As a result, the increase in risks to health and safety would not be considered significant.

SIFT Scenario 1 – Single Weapon with Intercept

The potential impacts associated with SIFT Scenario 1 would increase the exposure to health and safety risks from those found in the GTs. Impacts would include potential impacts from laser operation including handling laser chemicals and potential contact with the laser beam. Potential impacts to health and safety from launches include exposure to explosives, contact with launch debris, and exposure to noise produced during launch.

Impacts to health and safety from activities associated with SIFT Scenario 1 would depend on the biome in which launches and intercept took place. Because launches would take place on facilities or at locations with restricted access, members of the public would not be exposed to these hazards. Operating procedures would be developed to protect personnel, reducing any potential impacts to less than significant levels. Individuals exposed to health and safety risks would be DoD or DoD contractor personnel, other participants in the test, and other support, security, or observer personnel. All personnel exposed to elevated health and safety risks would be trained and certified for such risks, while the remaining test personnel would be briefed on the health and safety risks in accordance with appropriate and relevant regulations and standard operating procedures. The establishment of restricted impact areas and adherence to applicable regulations and standard operating procedures would reduce impacts from debris to less than significant levels.

SIFT Scenario 2 – Multiple Weapons with Multiple Intercepts

The activities associated with SIFT Scenario 2 would result in an increased exposure to health and safety risks in comparison to those associated with SIFT Scenario 1. The increased exposure to health and safety risks associated with SIFT Scenario 2 would not be expected to result in a significant impact.

4.1.2.7 Noise

Integrated GTs

Impacts from noise as a result of GTs would be limited to noise associated with the operation of generators required to activate sensors and C2BMC. Noise impacts from generators would be dependent on the intensity, the duration, and the proximity of the noise to sensitive receptors. The generators would be operated during tests, and sea- and

air-based systems typically would not be operated in proximity to sensitive receptors. Site-specific environmental analysis would be completed to evaluate potentially significant impacts. However, in general, the increase in noise from multiple generator use within a biome would not be significant.

SIFT Scenario 1 – Single Weapon with Intercept

Potential impacts from noise associated with SIFT Scenario 1 would be greater than those associated with GTs. For a target launch and the activation of a laser or launch of an interceptor, up to two sonic booms would be generated. The sonic booms could each produce overpressures as high as 8 to 16 pounds per square foot; however, these would be of short duration, lasting up to several milliseconds. Noise produced above 12,192 meters (40,000 feet) would not affect ground level noise. In addition, launches would occur at locations where members of the public would not be exposed to launch noise in excess of OSHA regulations. Personnel associated with launch would either be removed from the launch location or would use hearing protection to reduce exposure to less than significant levels. Impacts would be dependent on the biome in which launches and intercept took place. However, in general, noise associated with SIFT Scenario 1 would not be significant.

SIFT Scenario 2 – Multiple Weapons with Multiple Intercepts

The activities under SIFT Scenario 2 would result in increased noise levels when compared to SIFT Scenario 1. Activities under SIFT Scenario 2 will be evaluated for noise on a case-by-case basis.

4.1.2.8 Transportation

Integrated GTs

Impacts to transportation as a result of GTs would be limited to those associated with radar sensors. Air and marine transportation could be impacted by EMR emissions. Impacts to air transportation are described in Airspace. For marine transportation, NOTMARs would be issued in advance of the testing event to allow vessels to plan alternate routes to avoid the EMR hazard areas. The activation of multiple sensors in a biome would not significantly impact transportation.

SIFT Scenario 1 – Single Weapon with Intercept

In addition to the impacts presented under GTs, potential impacts to transportation from SIFT Scenario 1 would include temporary road closures around launch sites, expected flight trajectories, and debris impact zones. Debris recovery on land would require a relatively small number of vehicles. For SIFT Scenario 1 activities, areas around the

launch sites, the expected flight trajectories, and debris impact zone would be affected. However, closures of roads, airspace, and marine areas would be of short duration and would be considered routine occurrences for launch sites. Issuance of NOTAMs and NOTMARs would allow vehicles to clear the affected areas. All transportation of the components and support assets would be completed in accordance with the appropriate and relevant national and international standards and requirements. Therefore, no significant transportation impacts would be expected.

SIFT Scenario 2 – Multiple Weapons with Multiple Intercepts

The increase in transportation requirements or any increases in the frequency, duration, or number of transport route closures that would be required under SIFT Scenario 2 would not result in a significant transportation impact. All closures would be coordinated through the appropriate authorities.

4.1.2.9 Water Resources

Integrated GTs

GTs would involve an increase in risk for hazardous materials and hazardous waste spills and an increase in demand for potable water. Spills and leaks of hazardous materials and hazardous waste would be handled according to appropriate regulations and to the spill plans at each test site. Potable water supplies could be impacted, especially in areas with limited water supplies and infrastructure. The increase in personnel in these areas associated with GTs could exceed the capacity of the available potable water supply infrastructure. Site-specific environmental analysis would be completed to evaluate potentially significant impacts. However, in general impacts to water resources would not be significant.

SIFT Scenario 1 – Single Weapon with Intercept

Impacts to water resources from SIFT Scenario 1 would add to those associated with GTs. Impacts would include the generation of HCl from laser activation and launches of some boosters. For a target launch and the activation of a laser or launch of an interceptor occurring in the same biome, impacts to water resources would be dependent on the biome in which the launches and intercept took place. An early flight termination could result in propellant and debris from the target and interceptor being deposited in water bodies. Specific impacts on water resources are related to the biome and the unique or sensitive environments (wetlands, marine sanctuaries, essential fish habitat) that occur in the biome, which would be affected by such activities. Coordination and consultation with appropriate regulatory agencies would be required to address any potentially significant impacts on water resources. Impacts to water resources from laser

activation and launches occurring in different biomes would not have additive impacts of activities occurring within the same biome.

SIFT Scenario 2 – Multiple Weapons with Multiple Intercepts

In addition to the impacts presented under SIFT Scenario 1, the environmental impacts on water resources under SIFT Scenario 2 would result from increased pollutant emissions and subsequent deposition associated with the launches and successful intercepts or flight terminations. Site-specific environmental analysis would be completed to evaluate potentially significant impacts.

4.1.2.10 Orbital Debris

Integrated GTs

The amount of orbital debris would not be impacted by GTs.

SIFT Scenario 1 – Single Weapon with Intercept

The amount of orbital debris could increase under SIFT Scenario 1, from GMD or boost phase intercepts in the upper atmosphere. Such increases in orbital debris would be temporary, as studies indicate that objects in orbit between 200 and 399 kilometers (123 to 248 miles) reenter the atmosphere within a few months. (Interagency Group [Space], 1989, as referenced in U.S. Department of the Air Force, 1998)

Orbiting objects lose energy through friction with the upper reaches of the atmosphere and various other forces. Over time, the object falls into progressively lower orbits and eventually falls to Earth. As the object's orbital trajectory draws closer to Earth, it speeds up and outpaces objects in higher orbits. Once the object enters the measurable atmosphere, atmospheric drag will slow it down rapidly and cause it either to burn up or deorbit and fall to Earth.

NASA has determined that a significant amount of debris does not survive the severe heating that occurs during reentry. (NASA, 2003a) Components that do survive are most likely to fall into the oceans or other bodies of water or onto sparsely populated regions. During the past 40 years an average of one cataloged piece of debris fell back to Earth each day. No serious injury or significant property damage caused by reentering debris has been confirmed. Although it cannot be determined with certainty how much debris would be produced under SIFT Scenario 1, the fact that the orbital debris would only be on orbit for a limited time, the majority of the orbital debris would burn up upon reentry into the Earth's atmosphere, other orbital debris that falls to Earth daily has not caused injury or significant property damage indicates that orbital debris associated with SIFT Scenario 1 would not pose significant impacts.

SIFT Scenario 2 – Multiple Weapons with Multiple Intercepts

Increases in orbital debris would be greater under SIFT Scenario 2 than SIFT Scenario 1. Under SIFT Scenario 2 additional space-based sensors and C2BMC assets would be used and therefore these platforms could also produce orbital debris. As with SIFT Scenario 1, it may also be possible for debris from boost or midcourse intercepts to become orbital debris until it reenters the Earth's atmosphere. As defined under SIFT Scenario 1, the orbital debris would not pose a significant impact.

4.1.3 Activities at Locations Outside of the Continental U.S.

Some MDA activities may occur outside the continental U.S. (OCONUS), its territories and possessions. Because NEPA and other environmental laws do not generally apply to OCONUS activities, various EOs and DoD directives and instructions have been implemented. Appendix G describes the framework within which the MDA activities must comply regarding these international activities.

Impacts Analysis for MDA OCONUS Activities and Facilities

To conduct an analysis of potential impacts from proposed OCONUS BMDS activities, MDA considered global biomes based on similar ecological characteristics rather than political boundaries. The activities conducted in international locations would have the same emissions and stressors on resource areas as those conducted within the U.S. and its territories, e.g., types and amounts of emissions and noise from booster launches. However, the receiving environment may be very different and international regulatory requirements may have different standards for what constitutes a trigger for significance of impacts. The framework in terms of overseas environmental planning and compliance issues is addressed in Appendix G.

4.1.4 Cumulative Impacts

The proposed action addressed in this PEIS is the development, testing, deployment, and planning for decommissioning for an integrated BMDS to protect the U.S., its allies, and its interests worldwide. Thus this action is worldwide in scope and potential application, and only activities similar in scope have been considered for cumulative impacts. Regional or local past, present, or future activities would be considered for cumulative impact assessment as appropriate, during subsequent site- or action-specific NEPA analyses. Worldwide launch programs for commercial and government programs were determined to be activities of international scope that might reasonably be considered for cumulative impacts in this PEIS. Launches can contribute to cumulative impacts in three specific areas – ozone depletion, global warming, and orbital debris.

The number of BMDS projected launches was estimated at 515[54] during the years 2004 to 2014. Worldwide projected launches, which include 77 U.S. commercial launches (FAA AST, 2003); 99 U.S. government launches (NASA, 2003a; NASA, 2003b; NASA, 2003c); 183 foreign commercial launches (COMSTAC, 2003); and 476 foreign government launches (NASA, 2004; Gunter's Space Page, 2004; Spaceflight Now, 2004a; Spaceflight Now, 2004b), were estimated to total 835 launches during the years 2004 and 2014.

Exhibit 4-13 summarizes both BMDS and other worldwide launch emission loads to the stratosphere, based on the projected number of launches identified above. Note that the load to the troposphere would be the same as the load to the stratosphere because the residence time is assumed to be the same and the propellant types used are assumed to be the same (see Appendix I for assumptions used to estimate launch emissions loads).

Exhibit 4-13. Summary of Estimated Emission Loads to the Stratosphere from Launches (2004-2014) in metric tons (tons)*

	HCl	Al_2O_3	CO_2	H_2O	N_2	Cl	NO_X	CO
BMDS Projected Launches	1,344 (1,481)	2,432 (2,680)	3,118 (3,436)	1,810 (1,994)	0 (0)	18 (20)	1,821 (2,006)	0 (0)
Worldwide Projected Launches	6,526 (7,192)	11,777 (12,979)	57,287 (63,130)	50,298 (55,429)	0 (0)	87 (96)	94,933 (104,616)	0 (0)
Total Projected Launches	7,870 (8,673)	14,210 (15,659)	60,404 (66,566)	52,108 (57,413)	0 (0)	105 (116)	96,754 (106,623)	0 (0)

*Calculations subject to rounding; see Appendix I for additional information on launch emission load calculations and related assumptions

Global Warming

Potential launch emissions that could affect global warming include CO and CO_2. Unlike CO_2, CO is not a greenhouse gas; however, it can contribute indirectly to the greenhouse gas effect and is therefore included in this analysis. The cumulative impact on global warming from launches would be insignificant compared to other industrial sources (e.g., energy generation using fossil fuel) and activities (e.g., deforestation and land clearing). Estimated BMDS launch emissions load of CO and CO_2 to the troposphere and stratosphere would account for only five percent of the emissions load from launches worldwide. However, even when accounting for both BMDS launches and other launches worldwide, the CO and CO_2 load would be extremely small compared to

[54] Projected number of launches based on MDA estimates.

emissions loads from other industrial sources just in the U.S. As Exhibit 4-14 indicates, the amount of CO and CO_2 emissions load from all launches over the ten-year period under consideration would account for 3.5 x 10^{-4} percent of CO and CO_2 emissions load from U.S. industrial sources in one year.

Exhibit 4-14. Comparison of Emission Loads of CO and CO_2 to both the Troposphere and Stratosphere

Emission Sources	CO and CO_2 Emissions in metric tons (tons)*
BMDS Projected Launches from 2004-2014	6,235 (6,871)
Worldwide Projected Launches from 2004-2014	114,573 (126,260)
Other Industrial Sources in the U.S.**	34 billion (37.6 billion) for one year 136.3 billion (150.2 billion) for four years

Ozone Depletion

Ozone depletion is a major concern, as the stratospheric ozone layer protects the Earth from adverse levels of ultraviolet radiation. Chlorine is a chemical of primary concern with respect to ozone depletion. Launches are one of the human-made sources of chlorine in the stratosphere. The cumulative impact on stratospheric ozone depletion from launches would be far below and indistinguishable from the effects caused by other natural and man-made causes. Projected BMDS launches would include boosters considerably smaller than those used on the Space Shuttle; therefore, the air quality impacts from the Space Shuttle provide a conservative upper bound for comparison.

As Exhibit 4-15 indicates, the emission loads of chlorine (as HCl and free Cl) from both BMDS and other launches worldwide as projected from 2004-2014 would account for only 0.5 percent of the industrial Cl load from the U.S. over the 10-year period. The majority of the chlorine load from launches is as HCl, which does not readily break down into the ozone-depleting substance Cl. Also, the HCl in the troposphere is usually quickly removed by water in the atmosphere. The emissions load of chlorine from launch activities would also be minimal in comparison to the 362,874 metric tons (400,000 tons) of inorganic chlorine created annually by photolysis of historical reservoirs of CFCs. (DOT, 2001b)

Exhibit 4-15. Comparison of Emission Loads of Chlorine (HCl and Free Cl) in both the Troposphere and Stratosphere

Emission Source	Cl Emissions in metric tons (tons)*
Projected BMDS Launches 2004-2014	2,724 (3,002)
Projected Worldwide Launches 2004-2014	13,226 (14,580)
Other Industrial Sources in the U.S 2004-2014**	2,993,694 (3,000,000)

* Calculations subject to rounding
**Source: Adapted from DOT, 2001b

Almost all of the studies to date on ozone depletion from launches are based upon homogenous gas phase chemistry, which does not address the effects from particulates and aerosols released during ascent. There are no commonly accepted models that accurately predict the effects from particulates and aerosols on ozone depletion caused by launches. Future analysis of launches using heterogeneous chemistry could significantly alter the understanding of cumulative impacts of launch emissions on stratospheric ozone depletion. There is some evidence that particulates may play a larger role in ozone-depletion reactions than has currently been demonstrated. If this were the case, assuming only homogeneous gas phase chemistry (i.e., no effects from particulates or aerosols), the amount of ozone depletion actually occurring as a result of emissions from launches would be underestimated.

Orbital Debris

Orbital debris would be produced by space-based BMDS sensors and space-based C2BMC components and could be produced by midcourse and boost phase intercepts with sufficient energy. The effects of orbital debris on other spacecraft would depend on the altitude, orbit, velocity, angle of impact, and mass of the debris. Debris less than 0.01 centimeter (0.004 inch) in diameter can cause surface pitting and erosion. Over a long period of time, the cumulative effect of individual particles colliding with a satellite might become significant because the number of particles in this size range is very large in LEO. Long-term exposure of payloads to such particles is likely to cause erosion of exterior surfaces and chemical contamination, and may degrade operations of vulnerable components such as optical windows and solar panels. Debris between 0.01 and 1 centimeter (0.004 and 0.4 inch) in diameter could cause significant impact damage that could be serious, depending on system vulnerability and defensive design provisions. Objects larger than 1 centimeter (0.4 inch) in diameter can produce catastrophic damage. Although it is currently practical to shield against debris particles up to one centimeter (0.4 inch) in diameter (a mass of one gram [0.05 ounce]), for larger debris, current shielding concepts become impractical. (Office of Science and Technology Policy, 1995, as referenced in U.S. Department of the Air Force, 1998)

Astronauts or cosmonauts engaging in extra-vehicular activities could be vulnerable to the impact of small debris. On average, debris one millimeter (0. 04 inch) in diameter is capable of perforating current U.S. space suits. (Cour-Palais, 1991, as referenced in Commission on Engineering and Technical Systems, 1995)

Solid rocket motors eject Al_2O_3 dust (typically less than 0.01 centimeter [0.004 inch] in diameter) into the orbital environment, and may release larger chunks of unburned solid propellant or slag. However, solid rocket motor particles typically either decay very rapidly, probably within a few perigee passages, or are dispersed by solar radiation pressure. Thus, the operational threat of solid rocket motor dust is probably limited to brief periods of time related to specific mission events. (Office of Science and Technology Policy, 1995, as referenced in U.S. Department of the Air Force, 1998)

Orbital debris generated by launch vehicles contributes to the larger problem of pollution in space that includes radio-frequency interference and interference with scientific observations in all parts of the spectrum. For example, emissions at radio frequencies often interfere with radio astronomy observations. (Office of Technology Assessment, 1990, as referenced in U.S. Department of the Air Force, 1998) Not only can orbital debris interfere with the performance of scientific experiments, but also it can even accidentally destroy them. (Scheraga, 1986, as referenced in U.S. Department of the Air Force, 1998)

Orbiting objects lose energy through friction with the upper reaches of the atmosphere and various other forces. Over time, the object falls into progressively lower orbits and eventually falls to Earth. As the object's orbital trajectory draws closer to Earth, it speeds up and outpaces objects in higher orbits. Once the object enters the measurable atmosphere, atmospheric drag will slow it down rapidly and cause it either to burn up or deorbit and fall to Earth.

NASA has determined that a significant amount of debris does not survive the severe heating that occurs during reentry. (NASA Orbital Debris Program, 2003) Components that do survive are most likely to fall into the oceans or other bodies of water or onto sparsely populated regions like the Canadian Tundra, the Australian Outback, or Siberia in the Russian Federation. During the past 40 years an average of one cataloged piece of debris fell back to Earth each day. No serious injury or significant property damage caused by reentering debris has been confirmed. Although it cannot be determined with certainty how much debris would be produced from BMDS activities, or how much debris is produced by worldwide launches annually, the fact that orbital debris reenters on a daily basis and this debris has not caused injury or significant property damage indicates that orbital debris produced by BMDS space-based sensors would not pose significant impacts. Therefore the cumulative impacts of orbital debris for Alternative 1 are expected to be less than significant.

4.2 Alternative 2 – Implement BMDS Using Land-, Sea-, Air-, and Space-Based Weapons Platforms

Alternative 2 includes the use of weapons from land-, sea-, air-, and space-based platforms. The impacts associated with the use of weapons from land, sea, and air platforms would be the same as discussed for Alternative 1. Therefore, the analysis for this alternative will focus only on the additional impacts of using weapons from space-based platforms. Although MDA has historically conducted research and development efforts on space-based lasers, these efforts have been put on hold as kinetic energy missile technology, which is more promising in the short term, is being pursued. Therefore, this PEIS only addresses space-based interceptor technology and any future application of lasers from a space platform would be addressed as required.

4.2.1 Impacts Analysis

If Alternative 2 were selected, additional environmental analysis could be needed as the technologies intended to be used become more defined and robust. Because the impacts associated with the use of interceptors from space-based platforms are not environment specific, the impacts analysis for this alternative will not discuss specific environments.

The life cycle activities for space-based interceptors would be as described in Section 4.1 and in Exhibit 4-3.

For purposes of impacts analysis for space-based interceptors it was assumed that all manufacturing activities impacts would be the same as those discussed for Alternative 1. Therefore, they are not discussed for Alternative 2.

Space-based interceptors would be launched on launch vehicles and maintained from platforms similar to other satellites used for DoD and commercial purposes in a prescribed orbit around the Earth. The launch vehicles used to insert the weapon platforms into the proper orbit would likely be existing launch vehicles; and therefore, the impacts of the launch would be as described for Support Assets.

The impacts associated with the use of space-based interceptors and debris and deorbiting are unique to space and are discussed in some detail in this section. The NEPA and EO 12114, which require review of the environmental impact of certain Federal actions, do not apply to impacts in space. However, this PEIS considers the impacts that space-based objects, including orbital debris, might have on the terrestrial environment. Therefore, this analysis will focus on the impact to Earth of the launch of interceptors and the reentry of orbital debris.

Interceptors

Interceptors may be used from space-based platforms. Although preliminary design and development has been considered for a space-based interceptor, in the future MDA may develop and test other space-based interceptor designs.

Space-based interceptors would most likely be placed in LEO via existing launch vehicles. The booster used on the space-based interceptor would be either a pre-fueled liquid propellant booster or a solid propellant booster, with properties similar to those interceptors described in Alternative 1. It is unlikely that a non-pre-fueled liquid propellant would be used on a space platform. The interceptor and platform would likely be composed of aluminum, magnesium, carbon resin composites, titanium, and limited quantities of beryllium.

Space-based interceptors would be capable of providing defense against threat missiles in all flight phases. Because of this, the launch scenario may direct the interceptor towards Earth along a trajectory to intercept a threat missile. In planning test activities, the MDA would select launch scenarios that would result in both the interceptor and the debris impacting in designated areas either in the ocean or on cleared land-based ranges. The space-based interceptors may also be equipped with an FTS that, in the event of a launch mishap, would be activated to destroy the interceptor. The resulting debris from the interceptor would be the same as that produced during a successful intercept and would be as discussed for other debris.

Orbital Debris

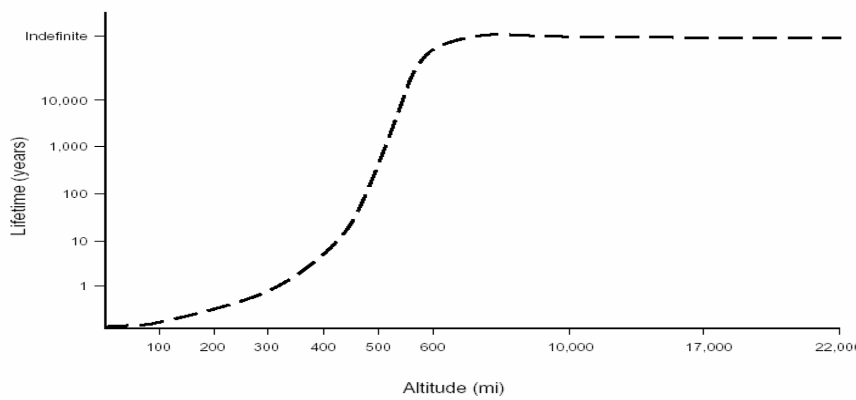
Orbital debris presents the most significant deviation from the impacts described for Alternative 1. Orbital debris generally refers to material that is on orbit as the result of space initiatives, but is no longer serving any function. Orbital debris can return to Earth via controlled or planned deorbiting or via uncontrolled deorbiting. Using interceptors from a space-based platform would create orbital debris, from successfully intercepting a threat missile and causing it to break up or from the break up of an unsuccessful interceptor or the space platform.

Space-based weapons platforms would contribute to orbital debris while in orbit and upon deorbiting, potentially hitting other satellites in their paths. The U.S. Air Force Space Command, located inside Cheyenne Mountain AFS, Colorado, tracks objects larger than 10 centimeters (4 inches) in diameter orbiting Earth. Space surveillance conducted by U.S. Space Command includes reentry assessment to predict when and where an object would reenter the Earth's atmosphere. U.S. Space Command does not, however, make surface impact predictions. NASA estimates that there are over 9,000 objects larger than 10 centimeters (4 inches) in diameter in space. The estimated population of particles between 1 and 10 centimeters (0.4 and 4 inches) in diameter is

greater than 100,000, and the number of smaller particles probably exceeds tens of millions. (NASA, 2001, as referenced in U.S. Department of the Air Force, 1998)

The addition of orbital materials from the operation of space-based weapons would contribute to the accumulation of orbital debris in LEO. Unless reboosted, satellites in orbits at altitudes of 200 to 399 kilometers (124 to 248 miles) reenter the atmosphere within a few months. At orbital altitudes of 399 to 900 kilometers (248 to 559 miles), orbital lifetimes can exceed a year or more depending on the mass and area of the satellite. Above 900-kilometer (559-mile) altitudes, orbital lifetimes can be 500 years or more. (Interagency Group [Space], 1989, as referenced in U.S. Department of the Air Force, 1998) Exhibit 4-16 shows the relationship between altitude and orbital lifetime.

Exhibit 4-16. Relationship between Altitude and Orbital Lifetime



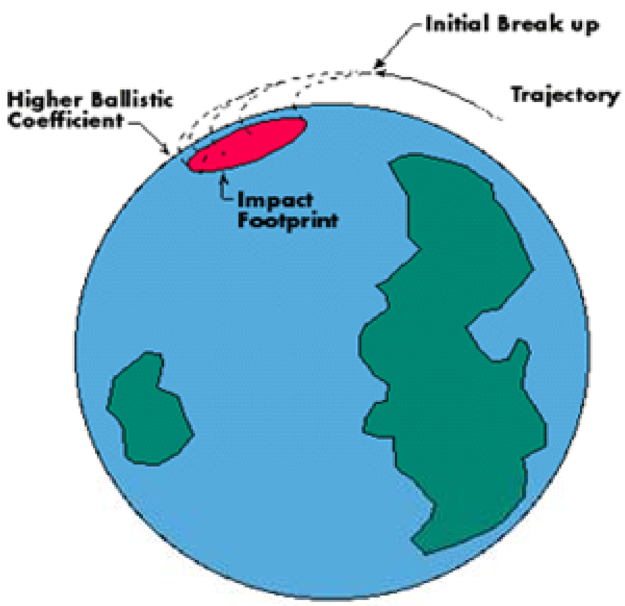
Debris in orbit gradually loses altitude. When orbiting objects enter dense regions of the atmosphere, friction between the object and atmosphere generates heat. This heat can melt or vaporize all or portions of the object resulting in minimal amounts of debris reaching the surface of the Earth. During reentry, the deceleration of the debris creates loads on the structure that can exceed ten times the acceleration of gravity. These loads combine with the high temperature to cause the debris to break apart.

Some debris can survive reentry heating. This occurs if the debris component’s melting temperature is high, or if its shape enables it to lose heat fast enough to keep the temperature below the melting point. (Aerospace Corporation, Center for Orbital Reentry and Debris Studies, 2003) In general, components made of aluminum and other materials with low melting temperatures do not survive reentry, while components made of materials with high melting temperatures, such as stainless steel, titanium, and glass, often do survive. Large pieces with moderate melting temperatures can also survive reentry, radiating heat over their large surface areas. Pieces that survive reentry tend to

be large and in some cases heavy, posing a significant hazard to people and property within the bounds of the object's reentry debris footprint. (Aerospace Corporation, Center for Orbital Reentry and Debris Studies, 2003) When possible, debris impact areas would be carefully selected to include deep ocean areas or designated locations on military ranges. However, the majority of orbital debris burns on reentry and thus does not reach the Earth. It is unlikely that the impact of debris associated with an uncontrolled reentry would pose a significant threat to the environment on Earth.

Debris that survives reentry would impact within debris or impact footprints, i.e., the areas on the land or water surfaces that would contain all of the debris pieces. Debris is more likely to terminate in water than on land because water covers 75 percent of the Earth's surface. Debris falling into water would produce impacts similar to those described for postlaunch activities in Alternative 1. It is possible to estimate the size of the impact footprint, but very difficult to predict precisely where the footprint would be on the Earth's surface or where specific pieces of debris would land. Exhibit 4-17 shows the various phases of reentry. After initial and subsequent breakups, surviving pieces of the reentering object would hit down in the debris or impact footprint area.

Exhibit 4-17. Typical Satellite Breakup



Source: Aerospace Corporation, Center for Orbital Reentry and Debris Studies, 2003

The size of the debris footprint is determined by estimating the breakup altitude of the orbiting object; then by estimating the mass and aerodynamic properties of surviving debris. Heavy debris would generally travel farther downrange within the debris footprint; lighter material would generally fall near the point of intercept. Footprint lengths can vary from 185 to 2,000 kilometers (115 to 1,243 miles), depending on the characteristics and complexity of the object.

The footprint width is generally determined by the impact of wind on the falling debris objects, with heavy objects less affected than lighter ones. The breakup process also may affect the width of the footprint. For example, if the object should explode during reentry, fragments would be spread out across the footprint. A footprint width of 20 to 40 kilometers (12 to 25 miles) is typical, with the most pronounced effects near the part of the footprint closest to the point of intercept. (Aerospace Corporation, center for Orbital Reentry and Debris Studies, 2003)

Upon termination of the useful life of a space-based weapon, the weapon and its platform would be deorbited in a controlled fashion. The deorbiting process for a space-based interceptor would not be different from deorbiting activities for other DoD or commercial objects on orbit. During the controlled deorbiting process, the interceptor and its platform would either be placed in a disposal orbit, which is normally 300 kilometers (186 miles) above geosynchronous orbit, or lowered through the atmosphere where, after experiencing the friction and heat of reentry, remaining debris would be deposited in a designated area of the ocean. The majority of the platform would be expected to burn upon reentry. The on-board chemicals would also burn, destroying them; therefore, they would not pose a threat to human health or the environment. The impacts associated with debris from deorbiting the weapon and its platform would be similar to the impacts of debris from postlaunch activities described in Alternative 1.

Debris from a successful intercept or a launch mishap resulting in the activation of an FTS would reenter the Earth's atmosphere in an uncontrolled manner. Missions are designed such that in the event of an FTS action by the flight safety officer, debris will reenter and impact either the BOA or on land on cleared ranges. It is also possible that during the planned deorbiting of a platform, the platform would experience a failure or lose communications with the ground controllers in which case the platform may reenter in an uncontrolled manner. In either scenario, the majority of the debris and platform would burn during reentry, resulting in a small amount, if any, inert debris reaching the Earth's surface.

4.2.1.1 Air Quality

Impacts from Launch/Flight

The air emissions associated with launching an interceptor from a space-based platform would be the same as those emitted during launch from any platform discussed in Alternative 1. However, emissions produced in a space environment would not affect the human environment; therefore, there would be no impact to air quality from space-based interceptors.

Impacts from Debris

Upon reentry, the majority of the space-based interceptor and its platform would burn due to the intense friction and heat created during reentry through the Earth's atmosphere. Any on-board hazardous materials would burn and would not pose a threat to human health or the environment. Some small particles and pieces of debris may serve as reaction sites for chemical reactions in the atmosphere; however, due to the infrequency of debris reentry and deorbiting events, the impacts would be insignificant.

4.2.1.2 Airspace

Impacts from Launch/Flight

Although launch of the interceptor would occur in space, the interceptor may be directed towards the Earth during intercepts and could impact the use of airspace in the interceptor's designated path. Any potentially affected airspace would be cleared before launch of the interceptor. Coordination with the appropriate FAA ARTCC and relevant military installations with responsibility for airspace management would minimize the potential for any adverse impacts to airspace use and scheduling.

Impacts from Debris

For controlled reentries, it would be possible to indicate an area of airspace that would need to remain cleared during reentry events. For uncontrolled reentries, current capabilities and procedures provide a limited ability to predict within a 30-minute, 9,656-kilometer (6,000-mile) window when and where a particular object would reenter the Earth's upper atmosphere. (U.S. Strategic Command, 2002) Given the difficulty in predicting the path of uncontrolled reentering space-based interceptors and their associated platforms, little advance warning could be given to clear airspace. However, most objects break up and vaporize under aerodynamic forces and heating that occur during reentry. Thus potential impacts to airspace are not expected to be significant.

4.2.1.3 Biological Resources

Impacts from Launch/Flight

The launch of interceptors from space-based platforms could result in impacts to biological resources. In the event that an intercept was attempted and was unsuccessful, the trajectory used by the interceptor could cause it to hit the Earth's surface. The trajectory for test events would be carefully selected such that the interceptor would impact in a cleared portion of the ocean or in a cleared military range. Also, space-based interceptors may be equipped with an FTS. In the event of a launch mishap, the FTS

would be activated to destroy the interceptor, which would further reduce impacts to biological resources.

Impacts from Debris

Upon reentry into the atmosphere, the majority of the interceptor and platform would be expected to break up and burn up due to the frictional forces and intense heat created upon reentry. Therefore, any on-board hazardous materials would also be consumed and would not pose a threat to biological resources. The remaining debris would fall to the Earth's surface and likely fall into open ocean waters where impact would be limited to fish and marine animals in the immediate surface waters surrounding the impact point. Fish and marine mammals at lower depths of the ocean would have more time to react to the sound of the impact and would be able to avoid the impact area.

Debris could potentially be scattered over a wide area. Factors affecting an object's path could include variations in the gravitational field of the landmass and ocean areas, solar radiation pressure, and atmospheric drag. Objects reentering may skip off the Earth's atmosphere, similar to a stone skipping across a pond, causing them to impact much further away than originally predicted and unintentionally disturbing wildlife and vegetation. (U.S. Strategic Command, 2002) The impacts of debris affecting biological resources would be similar to the impacts of postlaunch activities as described in Alternative 1.

4.2.1.4 Geology and Soils

Impacts from Launch/Flight

No impacts to geology and soils would be expected from the launch/flight of space-based interceptors.

Impacts from Debris

Because interceptor and station keeping platform propellants would likely be consumed during reentry into the upper atmosphere, debris and deorbiting activities for space-based weapons and their platforms would not be expected to release toxic substances that would impact soils.

The impact of debris from space-based weapons platforms or interceptors reaching the Earth's surface and creating craters or impacting unstable soils would be extremely unlikely, as most debris would not survive reentry. Debris that might survive reentry would likely be very small in size and would not create serious impact force on the surface. Further, when possible, debris impact areas would be carefully selected to include deep ocean areas or designated locations on military ranges, where impacts could

be contained. Because of the infrequency of debris reentry and the expected small size of surviving reentry debris, no significant impacts to geology or soils would be expected.

4.2.1.5 Hazardous Materials and Hazardous Waste

Impacts from Launch/Flight

The launch/flight of interceptors would not produce hazardous waste that would be transported to or disposed on Earth.

Impacts from Debris

Debris that is contaminated with hazardous materials would reenter the Earth's atmosphere and be exposed to high temperatures during reentry. This would likely render the debris inert by the time it reaches the Earth's surface. Debris and deorbited material would not be considered hazardous waste. Therefore, there would be no impact on hazardous waste management from space-based interceptor debris.

4.2.1.6 Health and Safety

Impacts from Launch/Flight

Launch trajectories would be selected such that, in the event of an unsuccessful intercept attempt, the debris from the interceptor launched from a space-based platform would impact in the open ocean area or in a designated area on land. This would minimize the possibility that health and safety of people on the ground would be affected by launch/flight activities. Also, space-based interceptors may be equipped with an FTS. In the event of a launch mishap, the FTS would be activated to destroy the interceptor, which would further reduce impacts to health and safety.

Impacts from Debris

Launch trajectories would be selected such that the debris from a space-based platform would impact in the open ocean area or in a designated area on land. This would minimize the possibility that health and safety of people on the ground would be affected by launch/flight activities. However, in the event of uncontrolled deorbiting, there is potential for the subsequent debris (devoid of any potentially harmful chemicals) to hit and injure humans. However, as mentioned above, humans only inhabit one-eighth of the Earth's surface; therefore, any impacts to health and safety expected from debris and deorbiting material would be minimal. The risk that an individual would be hit and injured by reentering orbital debris is estimated to be less than one in one trillion. As a reference point, the risk that an individual in the U.S. will be struck by lightning is approximately one in 1.4 million. Over the last 40 years, more than 1,400 metric tons

(1,543 tons) of material is estimated to have survived reentry with no reported casualties. (Aerospace Corporation, Center for Orbital Reentry and Debris Studies, 2003) Therefore, the impacts to health and safety expected from debris and deorbiting material would be negligible.

4.2.1.7 Noise

Impacts from Launch/Flight

No impacts from noise would be expected from the launch/flight of space-based interceptors.

4.2.1.8 Transportation

Impacts from Launch/Flight

There would be no impacts to transportation from launch/flight of space-based interceptors.

Impacts from Debris

Any orbital debris falling into the open ocean would most likely not be recovered. Debris recovery on land would be as described for Alternative 1, and would not have an impact on transportation.

4.2.1.9 Water Resources

Impacts from Launch/Flight

There would be no impacts to water resources from launch/flight of space-based interceptors.

Impacts from Debris

Upon reentry through the upper atmosphere, space-based interceptors and components would be subject to extreme heat, destroying residual chemicals or rendering them inert. Therefore, no impacts to water resources would be expected from debris and deorbiting material.

4.2.2 Test Integration

This section assesses the potential for environmental impacts of BMDS System Integration Test activities under Alternative 2.

Description of Tests Analyzed

The System Integration Tests would incorporate land-, sea-, air-, and space-based platforms for weapons, sensors, C2BMC, and support assets. The System Integration Test activities under Alternative 2 would be the same as those presented under Alternative 1.

In addition to the land-, sea-, and air-based interceptors described under Alternative 1, interceptors may be launched from space-based platforms under Alternative 2. All other activities and their associated impacts from System Integration Tests would be the same as those described under Alternative 1. GTs would not involve weapons components; however additional sensor and C2BMC components would be required to control and coordinate the activities of the four weapon platforms (land-, sea-, air-, and space-based) under Alternative 2. The System Integration Tests conducted under SIFT Scenarios 1 and 2 could include launches of interceptors from space-based platforms. Other aspects of these tests would be the same as described under Alternative 1.

Environmental Consequences

Component testing would continue under Alternative 2. These tests would be conducted in addition to the System Integration Tests described under Alternative 1; System Integration Tests conducted under Alternative 2 also could include the use of space-based interceptors. Space-based interceptors would replace a land-, sea-, or air-based weapon launch or activation. Space-based interceptors would be capable of providing defense against threat missiles in all flight phases.

Impacts from activities that are discussed earlier in this PEIS, including System Integration Tests using weapons from land-, air-, and sea-based platforms will not be discussed in this section. The analysis of System Integration Tests under Alternative 2 will focus on those environmental impacts that are unique to the use of space-based interceptors compared to those described for System Integration Test activities under Alternative 1.

The unique activities associated with each type of System Integration Test analyzed in this PEIS under Alternative 2 include

- **Integrated GTs**. The use of additional components to control and coordinate the activities of the four weapon platforms (land-, sea-, air-, and space-based).

- **SIFT Scenario 1 – Single Weapon with Intercept**. The launch of interceptors from space-based platforms with an intercept.

- **SIFT Scenario 2 – Multiple Weapons with Multiple Intercepts**. The launch of multiple interceptors from multiple weapon platforms (land-, sea-, air-, and space-based) at up to two targets with intercepts. Under Alternative 2, the following analysis assumes that the launch of a space-based interceptor would replace a land-, sea-, or air-based weapon launch or activation. The use of support assets or C2BMC during test events is addressed under Alternative 1.

Tests Not Analyzed By Resource Area

- **Integrated GTs**. The use of additional components to control and coordinate the activities of a space-based interceptor would result in a negligible increase in the severity of the impacts across the resource areas presented under Alternative 1; therefore, impacts from GTs will not be considered further in this section.

- **SIFT Scenario 1 – Single Weapon with Intercept**. Under Alternative 2, the launch of the interceptor from a space-based weapon platform instead of a land-, sea-, or air-based platform as described under Alternative 1, would result in a negligible reduction (a beneficial change) in the overall impacts on each resource area. Under Alternative 2 an interceptor launch from a space-based weapon would replace the interceptor launch from a land- or sea-based weapon, which would result in a reduction in ground level emissions. Based on the projected target intercept flight path of a space-based interceptor, Alternative 2 may result in fewer impacts to airspace than Alternative 1. If the flight path were limited to the exoatmosphere, Alternative 2 would have fewer impacts to airspace than Alternative 1; however, if the flight path were directed towards Earth for an endoatmospheric intercept the impacts to airspace would be the same as for Alternative 1. The impacts of the launch of a space-based interceptor would be reduced for air quality, airspace, biological resources, geology and soils, hazardous materials and hazardous waste, health and safety, noise, transportation, and water resources. The impacts of the launch of a space-based interceptor are addressed in Section 4.2.2.10.

  The impacts due to debris from launching an interceptor from a space-based platform are not unique for either SIFT scenario. Launching an interceptor from a space-based platform could allow intercepts to occur at higher levels of the atmosphere than described under Alternative 1, but the impacts due to debris reentry would be the same as those discussed earlier in this PEIS.

Tests Analyzed by Resource Area

- **SIFT Scenario 2 – Multiple Weapons with Multiple Intercepts**. The following sections present the environmental impacts, by resource area, for SIFT Scenario 2. For this programmatic analysis, a qualitative impact assessment for each resource area

was completed because specific System Integration Test parameters have not been developed that would provide quantitative values.

4.2.2.1 Air Quality

Under Alternative 2, there would be fewer impacts on air quality than under Alternative 1. Should an interceptor launch from a space-based weapon replace an interceptor launch from a land- or sea-based weapon, a reduction in ground level emissions would occur. If the activation of an air-based weapon were replaced, then a reduction in emissions would occur in the upper atmosphere (12,192 meters [40,000 feet]). The intercept would occur in the upper levels of the atmosphere, and would potentially occur in the exoatmosphere, where the majority of debris would burn upon reentry into the Earth's atmosphere.

4.2.2.2 Airspace

Under Alternative 2, there would be fewer impacts on airspace than under Alternative 1. Launch of an interceptor from space could result in a reduction in potential interference with airspace. Based on the projected target intercept flight path of a space-based interceptor, Alternative 2 may result in fewer impacts to airspace than Alternative 1. If the flight path is limited to the exoatmosphere, Alternative 2 would have fewer impacts to airspace than Alternative 1; however, if the flight path is directed towards Earth for an endoatmospheric intercept the impacts to airspace would be the same as for Alternative 1. Whether the intercept of a space-based weapon occurs in the endoatmosphere or exoatmosphere, the debris associated with an intercept of a space-based weapon would have the same impact on airspace as presented under Alternative 1. For exoatmospheric intercepts, the majority of the debris would burn upon reentry into the Earth's atmosphere; however, airspace would have to be cleared to allow for any debris from such an intercept to pass through the atmosphere to the surface of the Earth.

4.2.2.3 Biological Resources

Under Alternative 2, there would be fewer impacts on biological resources than under Alternative 1. Launch noise produced from a space-based interceptor would not reach the Earth. Therefore, tests under SIFT Scenario 2 would result in a reduction in noise and pollutant emissions associated with a launch or laser activation which could adversely affect biological resources. Specific impacts on biological resources would be related to threatened and endangered species, unique or sensitive environments, and migratory, breeding, and feeding activities that occur in an environment affected by such activities.

Coordination and consultation with appropriate regulatory agencies, as well as adherence to appropriate and relevant regulations would be required to address any potentially significant impacts on biological resources. Site-specific environmental analysis would be completed to evaluate such impacts.

4.2.2.4 Geology and Soils

The activities performed under Alternative 2 would not impact geology. Under Alternative 2, there would be fewer impacts on soil than under Alternative 1. If an interceptor launch from a space-based weapon would replace an interceptor launch from a land-based weapon there would be a reduction in ground level emissions; however, if launch of a sea- or air-based interceptor were replaced, there would be no change in the impact on soils.

4.2.2.5 Hazardous Materials and Hazardous Waste

Under Alternative 2, there would be fewer hazardous material and waste impacts than under Alternative 1. Fewer hazardous materials and hazardous waste would need to be disposed on Earth under Alternative 2. Such reductions would occur through the reduction of a launch or activation of a weapon from the human environment and the associated use of hazardous materials, and generation of hazardous waste. Because no impacts were identified under Alternative 1 from the increased use and generation of hazardous materials and hazardous waste, no significant impacts would be associated with Alternative 2.

4.2.2.6 Health and Safety

Under Alternative 2, there would be fewer health and safety impacts than under Alternative 1. Launching an interceptor from space rather than from land, air, or sea would result in a reduction in the number of individuals that would be exposed to health and safety risks associated with launch activities. Because no significant impacts were identified under Alternative 1 from the increased use and generation of hazardous materials and hazardous waste, no significant impacts would be expected from Alternative 2.

4.2.2.7 Noise

Under Alternative 2, there would be fewer noise impacts than under Alternative 1. Noise produced from the launch of interceptors from space-based platforms would not be audible on Earth. Because no significant impacts were identified under Alternative 1 from increased noise, no significant impacts would be expected from Alternative 2.

4.2.2.8 Transportation

The transportation impacts under Alternative 2 would be the same as the impacts under Alternative 1.

4.2.2.9 Water Resources

Under Alternative 2, there would be fewer impacts on water quality than under Alternative 1. An interceptor launch from a space-based weapon would replace an interceptor launch from a land-, sea-, or air-based weapon, which would result in a potential reduction in the debris and simulants that would reach a water resource based on the altitude where an intercept or flight termination would occur. Specific impacts on water resources are related to the unique or sensitive environments (wetlands, marine sanctuaries, essential fish habitat) that occur in the biome, which would be affected by such activities. Coordination and consultation with appropriate regulatory agencies, as well as adherence to appropriate and relevant regulations would be required to address any potentially significant impacts on water resources. Site-specific environmental analysis would be completed to evaluate potentially significant impacts.

4.2.2.10 Orbital Debris

- **SIFT Scenario 1 – Single Weapon with Intercep**t. Increases in orbital debris would be greater under Alternative 2 than under Alternative 1. Under Alternative 2 a higher proportion of the SIFT Scenario 1 tests would occur in the upper atmosphere because of testing associated with the space-based weapon. As defined under Alternative 1, the orbital debris would not pose a significant impact.

- **SIFT Scenario 2 – Multiple Weapons with Multiple Intercepts**. Increases in orbital debris would be greater under SIFT Scenario 2 than SIFT Scenario 1. Under SIFT Scenario 2 space-based interceptors, may be launched at a target in the upper atmosphere. As defined under Alternative 1, the orbital debris would not pose a significant impact.

4.2.3 Cumulative Impacts

As described for cumulative impacts from Alternative 1, worldwide launch programs for commercial, civil, and military programs were determined to be actions of international scope that could be appropriately considered for cumulative impacts in this PEIS. The impacts of worldwide launch programs were considered in the discussion of cumulative impacts for Alternative 1.

Alternative 2 includes placing weapons on all platforms considered for Alternative 1 (land, air, and sea) and placing weapons in space. The air emissions associated with launching interceptors from a space-based platform would be the same as those emitted during launch from any platform discussed in Alternative 1. However, emissions produced in a space environment would not affect the human environment; therefore, the cumulative impacts analysis for Alternative 2 does not address the additive impacts of emissions produced by launches from a space-based platform. Placing weapons in space

involves adding additional structures to space for extended periods of time; therefore, it is appropriate to include in this cumulative impacts analysis other programs that are international in scope which place structures in space for extended periods of time. The International Space Station (ISS) was determined to be an action that is international in scope and has a purpose of placing structures in space for extended periods of time. Therefore the cumulative impacts analysis for Alternative 2 encompasses the discussion of worldwide launch programs as discussed for Alternative 1 and includes a discussion of the impacts of the proposed BMDS in conjunction with the ISS.

The ISS is a collaborative project including contributions from 27 countries worldwide. As originally designed, the ISS would have a mass of about 471,736 kilograms (1,040,000 pounds) and would measure 109 meters (356 feet) across and 88 meters (290 feet) long, with almost an acre of solar panels. (ISS, 1999) The first piece of the ISS was placed into orbit on November 20, 1998; the ISS is still under construction and therefore the current orbiting structure does not meet the dimensions described above. However, the ISS the largest single human-made structure currently orbiting in space.

The ISS maintains an orbit around the Earth. The ISS and other man-made orbiting objects can be adversely affected by orbital debris. Orbital debris is produced during orbital launches and would be produced during some proposed BMDS test events and activities including those used to place space-based weapons on orbit. If the orbital debris produced during BMDS activities was located in orbits on the same plane or higher than the ISS the potential would exist for orbital debris to impact the ISS. The extent of the impact of orbital debris on structures depends on the size of the debris and the velocity at which it is traveling.

Debris as small as a fleck of paint approximately 0.02 centimeter (0.008 inches) in diameter traveling at a velocity of three to six kilometers per second (two to four miles per second) has been documented to create a 0.5 centimeter (0.2 inch) indention in the windshield of the Space Shuttle. In LEO, an aluminum sphere 0.13 centimeter (0.05 inch) in diameter has damage potential similar to that of a .22-caliber long rifle bullet. An aluminum sphere one centimeter (0.4 inch) in diameter is comparable to a 181-kilogram (400-pound) safe traveling at 97 kilometers per hour (60 miles per hour). A fragment 10 centimeters (3.9 inches) long is roughly comparable to 25 sticks of dynamite. In general, debris smaller than 0.1 centimeter (0.04 inch) in size does not pose a hazard to spacecraft functionality. Debris from 0.1 centimeter (0.04 inch) to one centimeter (0.4 inch) in size may or may not penetrate a spacecraft, depending on material and whether shielding is used. However, penetration through a critical component, such as the flight computer or propellant tank, can result in loss of the spacecraft. Debris fragments between one and 10 centimeters (0.4 and 3.9 inches) in size will penetrate and damage most spacecraft. Astronauts or cosmonauts engaging in extra-vehicular activities could be vulnerable to the impact of small debris. On average, debris

1 millimeter (0. 04 inch) is capable of perforating current U.S. space suits. (Cour-Palais, 1991, as referenced in Commission on Engineering and Technical Systems, 1995)

In general, any orbital debris produced by BMDS activities would likely be small, primarily consisting of explosive bolts and small pieces of hardware. It may also be possible for debris related to an intercept to become orbital debris. However, because the majority of BMDS activities would occur in LEO where debris would gradually drop into successively lower orbits and eventually reenter the atmosphere, the debris would not be a significant hazard to the ISS. As BMDS testing becomes more realistic, there is potential for an increased amount of debris reaching and remaining on orbit. Most of this debris would likely not remain on orbit for more than one revolution, and eventually all of the debris would de-orbit. NASA and its ISS partners may be able to implement mitigation strategies to further reduce the impacts to the ISS from orbital debris. NASA and the U.S. Air Force Space Command monitor orbiting space objects and are aware of instances when the ISS is predicted to be in proximity to space debris that has the potential to damage spacecraft.

MDA would evaluate risk to existing space assets prior to test launches as indicated in Appendix L Orbital Debris. MDA would use launch window screening and schedule tests to eliminate risk of BMDS intercept debris impacting the ISS. Because the debris produced by BMDS activities would be expected to be small and would eventually be removed from orbit, and MDA would schedule launches to avoid the ISS, there would be no significant impacts expected to the ISS from the implementation of Alternative 2 for the BMDS PEIS.

4.3 No Action Alternative

Under the No Action Alternative, the MDA would not develop, test, deploy, or plan for decommissioning activities for an integrated BMDS. Instead, the MDA would continue existing test and development of individual missile defense systems as stand-alone capabilities. Under the No Action Alternative, individual components would continue to be tested to determine the adequacy of their stand-alone capabilities, but they would not be subjected to System Integration Tests. Further, C2BMC architecture would be designed to meet individual components needs and would not be designed or tested to meet the needs of an integrated system. The No Action Alternative would not allow for the effective development of an integrated BMDS to defend against threat missiles in all flight phases.

The No Action Alternative involves the continuation of current MDA activities for individual weapons, sensors, C2BMC, and support assets and would not include integration or System Integration Testing of these components. For the potential sites being considered for deployment, the No Action Alternative would be a continuation of activities currently occurring or planned at those locations. Therefore, the environmental

impacts associated with the No Action Alternative would be the same as the impacts resulting from existing activities assuming no integration. Because System Integration Testing would not occur under the No Action Alternative, the impacts associated with this testing would not occur.

The decision not to develop and field a fully integrated BMDS could result in the inability to respond to a ballistic missile attack on the U.S. or its deployed forces, allies, or friends in a timely and successful fashion. Further, the No Action Alternative would not meet the purpose of or need for the proposed action or the specific direction of the President and the U.S. Congress.

4.4 Adverse Environmental Effects That Cannot Be Avoided

Adverse environmental effects that cannot be avoided include the removal of vegetation during site preparation and construction activities; minor short-term noise impacts startling of wildlife; deposition of small amounts of pollutants on land, air, and sea; minor increased generation of hazardous materials; and emission of EMR.

In general, most known adverse effects resulting from implementation of the BMDS would be mitigated through project planning and design measures, consultation with appropriate agencies, and the use of Best Management Practices. As a result, most potential adverse effects would be avoided and those that could not be avoided should not result in a significant impact to the environment. Consultation with the appropriate agencies would result in the development of mitigation measures needed to ensure that impacts remain at less than significant levels.

4.5 Relationship between Short-Term Use of the Human Environment and the Maintenance and Enhancement of Long-Term Productivity

Section 1502.16 of the CEQ NEPA Implementing Regulations; require that the relationship between short-term uses of the human environment and the maintenance and enhancement of long-term productivity be discussed.

Proposed BMDS activities would take advantage of existing facilities and infrastructure to the extent practicable. The implementation of the BMDS would not necessarily preclude the use of facilities and infrastructure for other purposes. Therefore, options for future use would not be eliminated.

4.6 Irreversible or Irretrievable Commitment of Resources

Implementing the BMDS would not be expected to result in the loss of threatened or endangered species or cultural resources. However, some irretrievable resources would be used (e.g., construction materials, fuel, and labor). Site preparation and construction activities would result in some minor loss of biological habitat and wetlands, but impacts

would be minimized through the implementation of mitigation measures. Sensitive biological habitat would be avoided to the extent practicable. Proposed BMDS activities would not irreversibly curtail the range of potential uses of the environment. There would be no preclusion of development of underground mineral resources that were not already constrained.

Although the proposed BMDS activities would result in some irreversible or irretrievable commitment of resources such as various construction materials, minerals, and labor, this commitment of resources is not significantly different from that necessary for many other defense research and development programs carried out over the past several years. Proposed activities would not commit natural resources in significant quantities.

4.7 Federal Actions to Address Protection of Children from Environmental Health Risks and Safety Risks (EO 13045, as Amended by EO 13296 and EO 13229)

This PEIS has not identified any environmental health and safety risks that may disproportionately affect children, in compliance with EO 13045 as amended by EO 13229.

6 LIST OF PREPARERS

This list presents the primary contributors to the technical content of this PEIS.

Government Preparers

Name: Martin Duke
Affiliation: MDA
Education: BS Civil Engineering, MS Engineering Management, Registered PE
Experience: Twelve years environmental compliance and acquisition management experience

Name: Col Allison Polchek
Affiliation: MDA
Education: JD, LLM Environmental Law
Experience: Nine years environmental assessment and NEPA experience

Contractor Preparers

Name: Deborah K. Shaver
Affiliation: ICF Consulting, MDA Contractor
Education: BS Chemistry, MS Chemistry
Experience: Thirty-one years environmental assessment management experience

Name: Sara Eisenstat
Affiliation: ICF Consulting, MDA Contractor
Education: BA Environmental Science and Policy
Experience: Two years environmental assessment experience

Name: Brantley Fry
Affiliation: ICF Consulting, MDA Contractor
Education: JD, BA Sociology
Experience: Two years environmental assessment experience

Name: Brenda Girod
Affiliation: ICF Consulting, MDA Contractor
Education: BA Personnel Administration, BS Journalism
Experience: Fifteen years environmental program management experience

Name: David Goldbloom-Helzner
Affiliation: ICF Consulting, MDA Contractor
Education: BA Chemistry, BS Engineering and Policy
Experience: Seventeen years air quality and health and safety analyses experience

Name: Pam Schanel
Affiliation: ICF Consulting, MDA Contractor
Education: BA Environmental Public Policy
Experience: Nine years environmental assessment experience

Name: Audrey Slesinger
Affiliation: ICF Consulting, MDA Contractor
Education: MSc Geology, BS Geology
Experience: Four years environmental assessment experience

Name: Todd Stribley
Affiliation: ICF Consulting, MDA Contractor
Education: MS Environmental Science and Policy, BS Biology
Experience: Eleven years environmental assessment experience

Name: Stacey Zee
Affiliation: ICF Consulting, MDA Contractor
Education: MS Environmental Policy, BS Natural Resource Management
Experience: Seven years environmental assessment experience

USSPACECOM	United States Space Command
VHF	Very high frequency
V/m	Volts per meter
VOC	Validation of Operational Concept
W/kg bw	Watts per kilogram body weight
XBR	X-Band Radar

APPENDIX K
COMMENT RESPONSE

COMMENT RESPONSE

Introduction

The Missile Defense Agency (MDA) received approximately 8,500 comment documents on the Draft Ballistic Missile Defense System (BMDS) Programmatic Environmental Impact Statement (PEIS). These comment documents were received via phone (0.14 percent), facsimile (0.08 percent), e-mail and through the electronic form available on the BMDS PEIS web site (5 percent), and mail (94 percent). To further facilitate public comment, the MDA held four public hearings

- October 14, 2004, Arlington, Virginia;
- October 19, 2004, Sacramento, California;
- October 21, 2004, Anchorage, Alaska; and
- October 26, 2004, Honolulu, Hawaii.

Both oral and written comments were received at the hearings constituting 0.70 and 0.14 percent, respectively, of the total comments.

Methodology for Considering Comments and Comment Documents

A comment document is defined as a document that is submitted by a commenter (e.g., letter, postcard, e-mail, telephone message, oral comment at the public hearing, etc.), and a comment is defined as a distinct statement or question about a particular topic. A comment document may contain several comments. The MDA logged in and assigned individual numbers to each comment document based on how the comment document was received. Comment documents are numbered as follows.

- Phone – DC_P0001
- Facsimile – DC_F0001
- E-mail/Web site – DC_E0001
- Mail – DC_M0001
- Public Hearing Oral – DC_PHO0001
- Pubic Hearing Written – DC_PHW0001
- Other – DC_O0001

Comment document numbers are listed in Exhibit K-1, which is organized alphabetically by commenter name. All comment documents received during the comment period were given equal consideration during preparation of the Final PEIS, regardless of the delivery method or commenter.

When public comments are large in number and volume, the National Environmental Policy Act (NEPA) does not require Federal agencies to reprint all written comments in

the Final Environmental Impact Statement (EIS). However, all comments must be considered in preparing the Final EIS. Council on Environmental Quality (CEQ) guidance states "if a number of comments are identical or very similar, agencies may group the comments and prepare a single answer for each group. Comments may be summarized if they are especially voluminous. The comments or summaries must be attached to the EIS regardless of whether the agency believes they merit individual discussion in the body of the final EIS."[1] For this PEIS, MDA included full text copies of all comment documents containing comments considered within the scope of the PEIS and specifically identified the comments requiring responses.

Template Letters

In sorting comment documents, MDA identified four distinct template letters that were submitted via e-mail, facsimile, or regular mail. These template letters, which are classified as Comment Template A, B, C, and D, are discussed in Section K.2. There were some variations of these template letters; therefore, Section K.2 provides randomly selected copies of variations of each of the four template letters.

Out of Scope Comments

NEPA requires Federal agencies to focus analysis and documentation on the significant issues related to a proposed action. Many of the comments received on the Draft PEIS were declarative statements not requiring a direct response, but which did need to be noted in the context of overall public review. Some of the comments received were related to budgetary or policy issues such as system cost, potential threat, and system effectiveness. These comments are considered outside the scope of this PEIS and require no revision to the PEIS and no direct response, except to note the comments for the record.

Section K.3 summarizes out of scope comments and provides the reasons why these comments do not require a substantive response. It should be noted that all comments were considered and the text of all comments and comment documents are included in the administrative record for the PEIS.

Comment Documents Containing In Scope Comments

Comment documents that contained substantive comments that were determined to be within the scope of this PEIS were identified. These comment documents are reproduced in Section K.4. In general, comments that addressed the resource areas analyzed in the Draft BMDS PEIS, feasible alternatives, relevant laws and regulations, and specific

---

[1] CEQ, Forty Most Asked Questions Concerning CEQ's National Environmental Policy Act Regulations, March 16, 1981. (46 *FR* 18026, March 23, 1981, as amended in 51 *FR* 15618, April 25, 1986)

comments relating to the impacts analysis, were considered to be within the scope of the PEIS.

Section K.4 includes reproductions of the original comment documents containing in-scope comments that were received during the public comment period for the Draft BMDS PEIS. Section K.4 also includes relevant excerpts of the in-scope comments and a response to each. Where appropriate, revisions to the Final BMDS PEIS were made to address these comments.

Comments Submitted by Federal Agencies

Several comment documents were submitted by Federal agencies, such as the United States (U.S.) Environmental Protection Agency (EPA) and the Department of the Interior. These comment documents are reproduced in Section K.5. Section K.5 also includes responses to each comment. Where appropriate, revisions to the Final BMDS PEIS were made to address these comments.

K.1 Summary of Commenters

It is important that each commenter be able to clearly identify that their comments were considered and where and how their comments were addressed. Exhibit K-1 organizes all comment documents by commenter name, comment document number, commenter organization, and section in this Appendix where specific comments from each comment document are addressed. As noted earlier, template letters are addressed in Section K.2, out of scope comments are addressed in Section K.3, in-scope comments are addressed in Section K.4, and comments submitted by Federal agencies are addressed in Section K.5. This exhibit is organized alphabetically by commenter's last name. If multiple signatures were provided on a comment document, the comment document is listed under the first signatory's name.

K.2 Template Letters

The MDA identified four template letters that were received via e-mail, facsimile, or U.S. postal service. These template letters are categorized as Comment Template A, B, C, and D. There were some variations of these template letters; therefore, the following sections include randomly selected variations of these letters. Comment documents that were included as variations of each template included several comment themes. Although the specific wording varied slightly the comment themes were the same. All of the comment documents in this group included some or all of the comment themes. The following sections include examples of the template letters, identified comment themes and the MDA's responses to those themes.

K.2.1 Comment Template A

K.2.1.1 Examples of Template A

Missile Defense Agency
BMDS PEIS
c/o ICF Consulting
9300 Lee Highway
Fairfax, VA 22031

Dear Mr. Lehner,

I am writing today to support the "No Action" alternative to deploying a missile defense system. The United States should not deploy a missile defense system unless it will improve the overall ecological, political, and security environment. On all three grounds, the proposed system fails.

Deployment of the Bush administration's proposed missile defense system threatens the global environment. It will increase the likelihood of a nuclear catastrophe by impelling Russia to maintain a larger nuclear arsenal on high alert than it otherwise would, and by driving China to build and deploy a larger arsenal than it otherwise would. The impact of a nuclear war, either accidental or intentional, would dwarf any other environmental nightmare scenario one can envision.

Moreover, the system does nothing to improve our security environment. It has yet to be tested in realistic conditions and would be ineffective against a real attack.

Deployment should be halted until the Programmatic Environmental Impact Statement is finished and the system succeeds in realistic testing.

Sincerely,

Oct 13, 2004

Rick Lehner
c/o ICF Consulting
9300 Lee Highway
Fairfax, VA 22031

Dear Mr. Rick Lehner,

I am writing today to support the "No Action" alternative to deploying a missile defense system. The United States should not deploy a missile defense system unless it will improve the overall ecological, political, and security environment. On all three grounds, the proposed system fails.

Deployment of the Bush administration's proposed missile defense system threatens the global environment. It will increase the likelihood of a nuclear catastrophe by impelling Russia to maintain a larger nuclear arsenal on high alert than it otherwise would, and by driving China to build and deploy a larger arsenal than it otherwise would. The impact of a nuclear war, either accidental or intentional, would dwarf any other environmental nightmare scenario one can envision.

Moreover, the system does nothing to improve our security environment. It has yet to be tested in realistic conditions and would be ineffective against a real attack.

Deployment should be halted until the Programmatic Environmental Impact Statement is finished and the system succeeds in realistic testing.

Sincerely,

K.2.1.2 Template A Comment Themes and Responses

Comment Theme 1. The BMDS would create an arms race "…by driving China to develop and deploy a larger arsenal than it otherwise would."

Response. These types of statements are conjectural in nature and are not appropriately addressed in a NEPA environmental analysis. Therefore, comments concerning the potential effect of the BMDS on the accumulation of weapons by other nations or groups were determined to be outside the scope of the BMDS PEIS.

Comment Theme 2. "Voting" for or "supporting" the No Action Alternative presented in the BMDS PEIS or supporting consideration of a "real" No Action Alternative.

Response. The CEQ's September 2002 report titled *CEQ Task Force Review of the NEPA Process: Summary of Public Comments* stated "It is important to recognize that the consideration of public comment is not a vote-counting process in which the outcome is determined by the majority opinion. Relative depth of feeling and interest among the public can serve to provide a general context for decision-making. However, it is the appropriateness, specificity, and factual accuracy of comment content that serves to provide the basis for modifications to planning documents and decisions. Further, because respondents are self-selected, they do not constitute a random or representative public sample." The comment period for the Draft PEIS does not encompass a voting

process for the alternatives. Therefore, these comments do not require a substantive response.

As noted in CEQ's "Forty Most Asked Questions", there are two interpretations of the No Action Alternative depending on the nature of the proposal being evaluated. In situations where "no action" is illustrated in instances involving Federal decisions on proposals for a project, "no action" would mean the proposed activity would not take place. In situations that involve an action such as updating a land management plan where ongoing programs initiated under existing legislation and regulations will continue, even as new plans are developed, "no action" may be thought of in terms of continuing with the present course of action until that action is changed. It is further noted that to construct an alternative based on no land management at all would be a useless academic exercise. For this PEIS, because the proposed action involves the integration of existing discrete missile defense systems, the no action alternative would be to continue with existing stand-alone systems; not to scrap all existing systems like the PATRIOT missile already in use in theater defense by U.S. forces.

Comment Theme 3. The BMDS has not been tested and would be ineffective in a real attack.

Response. This PEIS does not address issues related to DoD threat assessment policy or the technological feasibility of missile defense design. These comments regarding the effectiveness or ineffectiveness of the proposed system in defeating threat missiles were determined to be outside the scope of the BMDS PEIS and therefore do not require a substantive response. MDA has considered the environmental impacts of system integration flight testing in this PEIS. This testing would help MDA fine tune the various systems components of the BMDS and continue to identify additional functional capabilities needed to assure the security and efficacy of the system. However, the President made the decision to deploy a limited defensive capability to ensure the safety and security of the U.S. homeland while the system was being further developed and tested. Also, because the BMDS is a spirally developed defensive system, there may never be the ultimate deployment of a single architecture or even of a set of system architectures. Continuous improvement, technology development, and testing are critical to MDA's development of the BMDS.

Comment Theme 4. The BMDS would not improve the political environment.

Response. These types of statements are the opinion of the commenter and thus are not appropriately addressed in an environmental analysis. Therefore, comments concerning the potential effect of the BMDS on terrorism or global stability were determined to be outside the scope of the BMDS PEIS and do not require a substantive reply.

Comment Theme 5. The BMDS would not improve the security environment.

Response. These types of statements are the opinion of the commenter and thus are not appropriately addressed in an environmental analysis. Therefore, comments concerning the ability of the BMDS to defend against a realistic threat or provide safety for the U.S. were determined to be outside the scope of the BMDS PEIS and do not require a substantive reply.

Comment Theme 6. Deployment of the BMDS should be halted until the PEIS is finished and the system succeeds in realistic testing.

Response. This PEIS considers the environmental impacts from possible realistic testing scenarios that could be used to test the BMDS. However, this environmental analysis is not the appropriate venue to determine the outcome of testing or to determine when or how to deploy an integrated BMDS. Therefore, comments concerning deployment of the BMDS only after the success of realistic testing were determined to be outside of the scope of the BMDS PEIS and do not require a substantive reply.

Comment Theme 7. The BMDS would not improve the ecological environment.

Response. This comment reflects the opinion of the commenter. The PEIS analyzes the environmental impacts of the implementation of an integrated BMDS as discussed under Alternative 1 in Section 4.1.1; this includes the use of weapons, sensors, Command and Control, Battle Management, and Communications (C2BMC), and support assets for all of the resource areas described in Section 3. The environmental impacts of Test Integration under Alternative 1 are analyzed in Section 4.1.2. The impacts of activities at Locations Outside the Continental U.S. are discussed in Section 4.1.3. The cumulative impacts associated with Alternative 1 are considered in Section 4.1.4. The environmental impacts associated with Alternative 2 are addressed in Sections 4.2.1 Impacts Analysis, 4.2.2 Test Integration, and 4.2.3 Cumulative Impacts. The impacts of the No Action Alternative are addressed in Section 4.3. Thus the BMDS PEIS provides decision makers with information regarding potential environmental impacts of the proposed implementation alternatives so that effective decisions can be made about system implementation in the context of impacts to the environment.

Subject: Public Comment Re: Star Wars

To whom it May Concern:

I am writing to support the "No Action" alternative for the following reasons:

1) This new Star Wars program as outlined in the PEIS will be ***destabilizing*** thus creating new momentum to move the deadly and dangerous arms race into the heavens. This will create more global instability.

2) Testing and deployment of weapons in space will create massive amounts of new ***space debris*** making the environment of space even more contaminated and thus unavailable for future space flight.

2) This new Star Wars plan will be ***extraordinarily expensive*** requiring massive cuts in health care, education, public services, and environmental clean-up.

3) The likely use of ***nuclear power*** for eventual space-based weapons would be an environmental disaster.

4) Space-based weapons, described in the PEIS as being "defensive", could easily serve an ***offensive purpose*** as outlined in the Space Command's *Vision for 2020* that says the U.S. will "deny" other nations the use of space.

5) Toxic ***rocket exhaust pollution*** is now contaminating the Earth and punching a hole in the ozone layer. This plan would dramatically expand these polluting launches.

In light of the above and the huge cost of this plan at a time when people in our country and around the globe are suffering so greatly due to lack of basic human needs, I feel it is morally imperative to turn away from this project and work for the good of humanity on this earth.

Sincerely,

Subject: Ballistic Missile Defense System

I understand the public is invited to comment on PEIS before Nov 17th. So here I am.
I was a high school science teacher for 24 years. So I have studied and learned about the dangers and effects of radiation.
I believe the current "no action alternative" is insuffiicient and should be rewritten for the following reasons:
1) Nuclear reactors and systems should be kept out of space because that move will only increase the arms race.
2) Even though the purpose of space-based weapons would be "defensive", they could be used for "offensive" purposes. (we don't want to start any nuclear wars. I have had a first-hand view of Hiroshima in 1945 since I was overseas with the USO entertainung the troops.)
3) We don't want to increase polluting rocket launches. (The ozone layer is already being damaged thus creating climate change.)
The money could be put to much better use for health care, education, public services, etc.

Subject: pentagon star wars plan

I support the "No Action Alternative" in relation to the pentagon star wars plan because of the following reasons: (1) rocket exhuast and space debris from testing in space could pollute outer space and increase the ozone depletion already exixsting and (2) the fabulous ly expensive cost of this program. The Bush Administration has already created record debts and I don't see any hope for this problem being solved anytime soon. There are enough problems on earth without making more in space. I am not naive and realize that the Bush Administration loves giving money to the military industrial corporate complex, but aren't they already profiting enough on violence and death with Bush's invasion of Iraq? Money in defense of this country could be better spent on health care and social initiatives than on ridiculous space projects.

I firmly support the "No Action Initiative."

K.2.2.2 Template B Comment Themes and Responses

Comment Theme 1. The BMDS would be extraordinarily expensive.

Response. Budgetary policy issues including the cost of the proposed BMDS and other DoD related acquisition programs are not part of the decision to be made in this environmental analysis. Therefore, these types of issues were determined to be outside the scope of this PEIS. This PEIS considers the environmental impacts of various alternatives to develop, test, deploy, and plan for the decommissioning of an integrated BMDS.

Comment Theme 2. The cost of the BMDS will require spending cuts in other areas.

Response. Such comments on budgetary policy issues including how Federal funds should be spent provide an expression of personal or political philosophy or opinion. These types of comments do not address the environmental issues addressed in this PEIS and are outside the scope of the analysis.

Comment Theme 3. The BMDS would create an arms race.

Response. These types of statements are the opinion of the commenter and are thus not appropriately addressed in a NEPA environmental analysis. Therefore, comments concerning the potential effect of the BMDS on the accumulation of weapons by other nations or groups were determined to be outside the scope of the BMDS PEIS.

Comment Theme 4. The BMDS could be used as an offensive weapon.

Response. BMDS weapons are described as defensive system components that could be used to destroy threat missiles. Statements including those suggesting the use of these weapons for other purposes are the opinion of the commenter and are thus considered outside of the scope of the BMDS PEIS.

Comment Theme 5. "Voting" for or "supporting" the No Action Alternative presented in the BMDS PEIS or supporting consideration of a "real" No Action Alternative.

Response. The CEQ's September 2002 report titled *CEQ Task Force Review of the NEPA Process: Summary of Public Comments* stated "It is important to recognize that the consideration of public comment is not a vote-counting process in which the outcome is determined by the majority opinion. Relative depth of feeling and interest among he public can serve to provide a general context for decision-making. However, it is the appropriateness, specificity, and factual accuracy of comment content that serves to provide the basis for modifications to planning documents and decisions. Further, because respondents are self-selected, they do not constitute a random or representative public sample." The comment period for the Draft PEIS does not encompass a voting process for the alternatives. Therefore, these comments do not require a substantive response.

As noted in CEQ's "Forty Most Asked Questions," there are two interpretations of the No Action Alternative depending on the nature of the proposal being evaluated. In situations where "no action" is illustrated in instances involving federal decisions on proposals for project "no action" would mean the proposed activity would not take place. In situations that involve an action such as updating a land management plan where ongoing programs initiated under existing legislation and regulations will continue, even as new plans are developed, "no action" may be thought of in terms of continuing with the present course of action until that action is changed. It is further noted that to construct an alternative based on no management at all would be a useless academic exercise. For this PEIS, because the proposed action involves the integration of existing discrete missile defense systems, the no action alternative would be to continue with existing stand-alone systems; not to scrap all existing systems like the PATRIOT missile already in use in theater defense by U.S. forces.

Comment Theme 6. The BMDS will be politically destabilizing.

Response. These types of statements are the opinion of the commenter and are thus not appropriately addressed in an environmental analysis. Therefore, comments concerning the potential effect of the BMDS on terrorism or global stability were determined to be outside the scope of the BMDS PEIS and do not require a substantive reply.

Comment Theme 7. The BMDS would increase environmental damage including damage to the ozone layer from rocket launch emissions.

Response. Many generic environmental issues are considered in the PEIS. However, impacts to some resource areas including Cultural Resources, Environmental Justice, Land Use, Socioeconomics, Utilities, and Visual Resources are more appropriately considered in site-specific environmental documentation. Each of these was discussed

regarding methodology and thresholds for significance to provide a “roadmap” for performing future site-specific analyses tiering from the PEIS. The following resource areas were considered in the PEIS: Air Quality, Airspace, Biological Resources, Geology and Soils, Hazardous Materials and Hazardous Waste, Health and Safety, Noise, Transportation, Water Resources, and Orbital Debris.

The PEIS analyzes the environmental impacts of the use of BMDS Components under Alternative 1 in Section 4.1.1; this includes the use of weapons, sensors, C2BMC, and support assets for all of the resource areas described above. The environmental impacts of Test Integration under Alternative 1 are analyzed in Section 4.1.2. The impacts of activities at Locations Outside the Continental U.S. are discussed in Section 4.1.3. The cumulative impacts associated with Alternative 1 are considered in Section 4.1.4. The environmental impacts associated with Alternative 2 are addressed in Sections 4.2.1 Impacts Analysis, 4.2.2 Test Integration, and 4.2.3 Cumulative Impacts. The impacts of the No Action Alternative are addressed in Section 4.3.

Specifically, damage to the ozone layer from rocket launch emissions was considered in Section 4.1.1.2 for launches of interceptors and impacts on air quality including ozone depletion in the stratosphere.

K.2.3.1 Examples of Template C

October 20, 2004

Missile Defense Agency

MDA BMDS PEIS, c/o ICF Consulting
9300 Lee Highway
Fairfax, VA 22031

Missile Defense Agency:

I am writing to support a real "No Action" alternative to the deployment of a missile defense system. This means no further testing, development, or deployment. Deployment of such a system threatens a new nuclear arms race, puts the global environment at risk, and does not improve the security of the United States.

Deployment of a missile defense system will increase the likelihood of a nuclear catastrophe. It impels Russia to maintain a larger nuclear arsenal on high alert than it otherwise would. Deployment also drives China to deploy a larger arsenal. The impact of a nuclear war, whether accidental or intentional, would dwarf any other environmental nightmare one can envision.

Moreover, the system does not improve our security. So far, it has yet to be tested in realistic conditions and would be ineffective against an attack. While in the future the capabilities of the system can be expanded at great expense, these developments are likely to be made useless by the newly improved weapons and countermeasures of potential adversaries.

Finally, the $10 billion a year being spent on missile defense should be spent on measures that are more effective and environmentally sound. One example is the program to secure stockpiles of nuclear weapons material in the former Soviet Union and other countries.

The testing, development, and deployment of the missile defense system should be halted, given that the system leads to environmental harm and potentially to environmental devastation and does so without improving the security of the United States.

Sincerely,

October 24, 2004

Missile Defense Agency

Missile Defense Agency:

I am writing to support a real "No Action" alternative to the deployment of a missile defense system. This means no further testing, development, or deployment. Deployment of such a system threatens a new nuclear arms race, puts the global environment at risk, and does not improve the security of the United States.

Moreover, the system does not improve our security. So far, it has yet to be tested in realistic conditions and would be ineffective against an attack. While in the future the capabilities of the system can be expanded at great expense, these developments are likely to be made useless by the newly improved weapons and countermeasures of potential adversaries.

This is a waste of my hard-earned tax money. I do not feel more secure with such a system. I instead feel very insecure. Nuclear weapons are not the way to make me feel secure or defended. I think it would be better to use the monies on systems that are environmentally sound and are not potentially hazardous to me and others who are being defended.

The testing, development, and deployment of the missile defense system should be halted, given that the system leads to environmental harm and potentially to environmental devastation and does so without improving the security of the United States.

Sincerely,

K.2.3.2 Template C Comment Themes and Responses

Comment Theme 1. Monies slated for the BMDS should be spent on other programs or services.

Response. Comments on budgetary policy issues including how Federal funds should be spent provide an expression of personal or political philosophy or opinion. These types of comments do not address the environmental issues addressed in this PEIS and are outside the scope of the analysis.

Comment Theme 2. Deployment of the BMDS would create an arms race.

Response. These types of statements are the opinion of the commenter and thus are not appropriately addressed in a NEPA environmental analysis. Therefore, comments concerning the potential effect of the BMDS on the accumulation of weapons by other nations or groups were determined to be outside the scope of the BMDS PEIS.

Comment Theme 3. Supporting a "real" No Action Alternative.

Response. As noted in CEQ's "Forty Most Asked Questions," there are two interpretations of the No Action Alternative depending on the nature of the proposal being evaluated. In situations where "no action" is illustrated in instances involving Federal decisions on proposals for project, "no action" would mean the proposed activity would not take place. In situations that involve an action such as updating a land management plan where ongoing programs initiated under existing legislation and regulations will continue, even as new plans are developed, "no action" may be thought of in terms of continuing with the present course of action until that action is changed. It is further noted that to construct an alternative based on no management at all would be a useless academic exercise. For this PEIS, because the proposed action involves the integration of existing discrete missile defense systems, the no action alternative would be to continue with existing stand-alone systems; not to scrap all existing systems like the PATRIOT missile already in use in theater defense by U.S. forces.

Comment Theme 4. The BMDS has not been tested and would be ineffective in a real attack.

Response. This PEIS does not address issues related to DoD threat assessment policy or the technological feasibility of missile defense design. These comments regarding the technological feasibility of defeating threat missiles are the opinion of the commenter and were determined to be outside the scope of the BMDS PEIS and therefore do not require a substantive response. MDA has considered the environmental impacts of system integration flight testing in this PEIS. This testing would help MDA fine tune the various

systems components of the BMDS and continue to identify additional functional capabilities needed to assure the security and efficacy of the system. However, the President made the decision to deploy a limited defensive capability to ensure the safety and security of the U.S. homeland while the system was being further developed and tested. Also, because the BMDS is a spirally developed defensive system there may never be the ultimate deployment of a single architecture or even of a set of system architectures. Continuous improvement, technology development, and testing are critical to MDA's development of the BMDS.

Comment Theme 5. Potential adversaries will develop new weapons and countermeasures to render the BMDS ineffective.

Response. These types of statements are the opinion of the commenter and are thus not appropriately addressed in an environmental analysis. Therefore, comments concerning the potential effect of the BMDS on terrorism or global stability were determined to be outside the scope of the BMDS PEIS and do not require a substantive reply.

Comment Theme 6. The BMDS will not improve the security of the U.S.

Response. These types of statements are the opinion of the commenter and are thus not appropriately addressed in an environmental analysis. Therefore, comments concerning the ability of the BMDS to defend against a realistic threat or provide safety for the U.S. were determined to be outside the scope of the BMDS PEIS and do not require a substantive reply.

Comment Theme 7. The testing, development, and deployment of the BMDS damages the environment.

Response. The PEIS analyzes the environmental impacts of the implementation of the BMDS under Alternative 1 in Section 4.1.1, this includes the use of weapons, sensors, C2BMC, and support assets for all of the resource areas described in Section 3. The environmental impacts of Test Integration under Alternative 1 are analyzed in Section 4.1.2. The impacts of activities at Locations Outside the Continental U.S. are discussed in Section 4.1.3. The cumulative impacts associated with Alternative 1 are considered in Section 4.1.4. The environmental impacts associated with Alternative 2 are addressed in Sections 4.2.1 Impacts Analysis, 4.2.2 Test Integration, and 4.2.3 Cumulative Impacts. The impacts of the No Action Alternative are addressed in Section 4.3.

To: mda.bmds.peis
Subject: Comments on New Star Wars Program

To whom it may concern re: The new Star Wars program.

I strongly oppose any and all new Star Wars programs. The current "no action alternative" is insufficient, and the PEIS must be re-written for the following reasons:

- **Spending**. Time has proven that these types of programs take on a life of their own. Much of that life is an economic existence based on technological failures; a deadline missed, an unanticipated expense - and then evolves a process fueled by a new economic dependence on the American government tax dollars to succeed. We are not able to continue to fund such programs, which by their very nature create new dependencies on an already fragile economy.
- **Ecological Factors**. As an American living and traveling abroad, I live daily with the pollution created by economies driven by borrowed and irresponsible 'second-hand ' American technology gone amuck. Over time another new American technology will, in all probability, create envy and be used in yet another irresponsible way. The present American fear of escalating international nuclear proliferation is a case in point.
- **Moral Perspectives**. Much of the just completed American Presidential election was based on a development of ideas surrounding an American moral response based on fear of aggression and terrorism. Extending that argument to the whole world, what is the meaning of a common and global morality regarding this issue? My conclusion is that this proposal ignores the voices of much of the world.
- **Initiatives Based On Fear**. Feeding the fears of people may make this initiative popular with some, but it is the fear that must be addressed and not another military "objective" based on tactics that the Big Bad Wolf may get you, so prepare a house that is unassailable. Another model is needed.
- **Who Suffers?** To name but a few, there are the poor who continue to suffer from monies directed elsewhere, those countries that do not have a voice because they sit at an uneven economic table and an uneven power table with the rest of the world.
- **Tracking the Issue.** In a world that already has a short attention span for important issues and is daily saturated in such a way that we do not track these issues, it is critical that we not give people yet another initiative that will be quickly forgotten and, therefore, we will not pay attention to over time. This issue has huge and lasting global consequences.
- **Power**. Our global situation is already precarious and filled with many questions over which United States has exerted its power. Presently, this power is often perceived of as unjust. To add yet another initiative that will add to this feeling is not a model for a just society.

For the above and many other reasons, **I believe that the current "no action alternative" is insufficient, and the PEIS must be re-written**.

To whom it may concern re: The new Star Wars program.

I strongly oppose any and all new Star Wars programs. The current "no action alternative" is insufficient, and the PEIS must be re-written for the following reasons:

Spending. Time has proven that these types of programs take on a life of their own. Much of that life is an economic existence based on technological failures; a deadline missed, an unanticipated expense - and then evolves a process fueled by a new economic dependence on the American government tax dollars to succeed. We are not able to continue to fund such programs, which by their very nature create new dependencies on an already fragile economy.
Ecological Factors. As an American living and traveling abroad, I live daily with the pollution created by economies driven by borrowed and irresponsible 'second-hand ' American technology gone amuck. Over time another new American technology will, in all probability, create envy and be used in yet another irresponsible way. The present American fear of escalating international nuclear proliferation is a case in point.
Moral Perspectives. Much of the just completed American Presidential election was based on a development of ideas surrounding an American moral response based on fear of aggression and terrorism. Extending that argument to the whole world, what is the meaning of a common and global morality regarding this issue? My conclusion is that this proposal ignores the voices of much of the world.
Initiatives Based On Fear. Feeding the fears of people may make this initiative popular with some, but it is the fear that must be addressed and not another military "objective" based on tactics that the Big
Bad Wolf may get you, so prepare a house that is unassailable. Another
model is needed.
Who Suffers? To name but a few, there are the poor who continue to suffer from monies directed elsewhere, those countries that do not have a voice because they sit at an uneven economic table and an uneven power
table with the rest of the world.
Tracking the Issue. In a world that already has a short attention span for important issues and is daily saturated in such a way that we do not track these issues, it is critical that we not give people yet another initiative that will be quickly forgotten and, therefore, we will not pay attention to over time. This issue has huge and lasting global consequences.
Power. Our global situation is already precarious and filled with many questions over which United States has exerted its power. Presently, this power is often perceived of as unjust. To add yet another initiative that will add to this feeling is not a model for a just society.

For the above and many other reasons, I believe that the current "no action alternative" is insufficient, and the PEIS must be re-written.

K.2.4.2 Template D Comment Themes and Responses

Comment Theme 1. The BMDS would depend on American government tax dollars and would stress the economy.

Response. Budgetary policy issues including the cost of the proposed BMDS and other DoD related programs are not part of the decision to be made in this environmental analysis. Therefore, these types of issues were determined to be outside the scope of this PEIS. This PEIS considers the environmental impacts of various alternatives to develop, test, deploy, and plan for the decommissioning of an integrated BMDS.

Comment Theme 2. The BMDS would cause monies to be diverted away from other services and programs.

Response. Comments on budgetary policy issues including how Federal funds should be spent provide an expression of personal or political philosophy or opinion. These types of comments do not address the environmental issues addressed in this PEIS and are considered outside the scope of the analysis.

Comment Theme 3. Supporting a "real" No Action Alternative.

Response. As noted in CEQ's "Forty Most Asked Questions," there are two interpretations of the No Action Alternative depending on the nature of the proposal being evaluated. In situations where "no action" is illustrated in instances involving Federal decisions on proposals for project, "no action" would mean the proposed activity would not take place. In situations that involve an action such as updating a land management plan where ongoing programs initiated under existing legislation and regulations will continue, even as new plans are developed, "no action" may be thought of in terms of continuing with the present course of action until that action is changed. It is further noted that to construct an alternative based on no management at all would be a useless academic exercise. For this PEIS, because the proposed action involves the integration of existing discrete missile defense systems, the no action alternative would be to continue with existing stand-alone systems; not to scrap all existing systems like the PATRIOT missile already in use in theater defense by U.S. forces.

Comment Theme 4. The BMDS would add to an already precarious global situation.

Response. These types of statements are the opinion of the commenter and thus are not appropriately addressed in an environmental analysis. Therefore, comments concerning the potential effect of the BMDS on terrorism or global stability were determined to be outside the scope of the BMDS PEIS and do not require a substantive reply.

Comment Theme 5. Opposition to the "Star Wars" program.

Response. Alternative 1 would not include the use of space-based weapons while Alternative 2 would include the use of weapons from space-based platforms. While this PEIS considered two implementing alternatives for the BMDS, this PEIS performed an environmental analysis, not a policy analysis of the alternatives. The comments that were collectively summarized and grouped as *"Opposed to Weapons in Space"* were comments that expressed a philosophy, value, or opposition to an action. These comments were not substantive comments on the scope of the *environmental analysis* in this PEIS regarding the use of space-based weapons but rather statements against the *policy* of using space-based weapons. These comments appear to fit within the definition provided for non-substantive comments, i.e., comments that express a philosophy, value, or support or opposition for an action; therefore, it would appear to be appropriate to include them in this grouping. These types of issues are not part of the decision to be

made in this environmental analysis. Therefore, these comments were determined not to require a substantive reply.

Comment Theme 6. The BMDS technology will eventually be used in an irresponsible way leading to ecological risk.

Response. Many generic or non-specific environmental issues are considered in the PEIS. Some resource areas including Cultural Resources, Environmental Justice, Land Use, Socioeconomics, Utilities, and Visual Resources are more appropriately considered in site-specific environmental documentation. Each of these was discussed regarding methodology and thresholds for significance to provide a "roadmap" for performing future site-specific analyses tiering from the PEIS. The following resource areas were considered in the PEIS: Air Quality, Airspace, Biological Resources, Geology and Soils, Hazardous Materials and Hazardous Waste, Health and Safety, Noise, Transportation, Water Resources, and Orbital Debris.

The PEIS analyzes the environmental impacts of the use of BMDS Components under Alternative 1 in Section 4.1.1, this includes the use of weapons, sensors, C2BMC, and support assets for all of the resource areas described above. The environmental impacts of Test Integration under Alternative 1 are analyzed in Section 4.1.2. The impacts of activities at Locations Outside the Continental U.S. are discussed in Section 4.1.3. The cumulative impacts associated with Alternative 1 are considered in Section 4.1.4. The environmental impacts associated with Alternative 2 are addressed in Sections 4.2.1 Impacts Analysis, 4.2.2 Test Integration, and 4.2.3 Cumulative Impacts. The impacts of the No Action Alternative are addressed in Section 4.3.

K.3 Out of Scope Comments

After determining which comment documents had text that was the same as or similar to that provided in one of the four types of template letters, all comments were reviewed to determine if they addressed substantive or out of scope comments. Out of scope comments were grouped according to their subject matter and in accordance with 40 Code of Federal Regulations (CFR) § 1503.4 and "Forty Most-Asked Questions Concerning CEQ's National Environmental Policy Act Regulations" these comments were briefly summarized and the reasons why these comments were considered out of scope were documented.[2] Each subject matter topic and a summary of the comments received are presented in Sections K.3.1 through K.3.18. Examples of specific comments related to each topic are also provided. Following the summary and examples is an explanation of why these comments were determined to be out of scope. All comments received have been noted and will be included in the administrative record for this PEIS.

---

[2] The Council on Environmental Quality has determined that when a large volume of comments are received it is appropriate to summarize the comments rather than reproduce the comments in the NEPA document.

K.3.1 Opposed to the BMDS

Summary. Many commenters stated that they were opposed to the testing and/or development of missile defense technologies including those proposed for the BMDS.

Examples. "I say NO STAR WARS" (DC_E0017), "This Ballistic Missile Defense system has to be one of the most stupid plans ever invented to waste the resources of the people of the USA and create a new arms race based in space." (DC_E0021), "I strongly oppose any form of missle [sic.] defense system plan for space.NO! NO! NO!" (DC_E0062), "Pie in sky while overlooking bombs in our backyard - is NOT Smart and definitely dangerous. Shelve it!" (DC_E0089)

Response. As stated in Section 1.2 of the Draft BMDS PEIS, on January 2, 2002, Secretary of Defense Rumsfeld issued a directive to the DoD to establish a single development program for all the work needed to design, develop, and test elements of an integrated BMDS that would operate under a newly titled MDA. Therefore, it has been determined that a BMDS should be developed. This PEIS considers the environmental impacts of various implementing alternatives for such a system. Therefore, comments regarding opposition to the BMDS *per se* and other related policy issues were determined to be outside the scope of this environmental analysis.

K.3.2 Missile Defense Program is too Expensive, Opposed to Funding the BMDS

Summary. Many commenters expressed a belief that that missile defense development and testing is too expensive.
Examples. "I find the other two options a waste of money and a morally empty endeavor." (DC_E0029), "The precision in timing and location needed in order to intercept a missile makes this an unrealistic program, especially considering the outrageous costs of it." (DC_E0050), "Going forward with the planned BMDS appears both scientifically irrational, highly costly, and dangerous to our national security." (DC_E0074)

Response. Comments on budgetary policy issues including the cost of the proposed BMDS and other DoD related programs are not part of the decision to be made in this environmental analysis. Therefore, these types of issues were determined to be outside the scope of this PEIS. This PEIS considers the environmental impacts of various alternatives to develop, test, deploy, and plan for the decommissioning of an integrated BMDS.

K.3.3 Federal Funds should be used to Address Domestic or International Problems

Summary. Several commenters suggested that monies allocated to missile defense could be better spent to address other social domestic or international problems. Other commenters suggested that these funds should be spent decreasing the stockpile of

weapons in other countries rather than developing and testing a U.S. missile defense capability.

Examples. “The perception of a nation willing to forgo the funds desperately needed for education, for health and for the development of labor intensive industries that provide jobs, is the perception of a nation locked in the illusive pursuit of security, even at the risk of inducing weapons competition that will ultimately reduce security.” (DC_E0015), “Wouldn't the money be better spent on helping those countries where poverty is at levels which make people angry and may therefore lead to violence?” (DC_E0032), “Why would we incur the wrath of the rest of the world, commit to huge costs that undermine spending on the people's needs, endanger the planet's viability by further decimating its environmental balance and endanger the lives of billions?” (DC_E0055)

Response. Comments on budgetary policy issues including how Federal funds should be spent provide an expression of personal or political philosophy or opinion. These types of comments do not address the environmental issues addressed in this PEIS and are considered outside the scope of the analysis.

K.3.4 BMDS Would Create an Arms Race

Summary. Some commenters expressed concern that the development of a missile defense system by the U.S. would be viewed as a threat by other countries that would cause them to develop weapons systems to defeat the BMDS.

Examples. “First, they will multiply offensive missiles, ratcheting up the catastrophically expensive arms race.” (DC_E0007), “Its deployment unquestionably will accelerate the arms race into space - those who disagree with that likely assumption are very weak in their denial.” (DC_E0019), “This just continues the arms race.” (DC_E0058)

Response. These types of statements are the opinion of the commenter and are thus not appropriately addressed in a NEPA environmental analysis. Therefore, comments concerning the potential effect of the BMDS on the accumulation of weapons by other nations or groups were determined to be outside the scope of the BMDS PEIS.

K.3.5 Opposed to Nuclear Weapons

Summary. A few commenters stated that they were opposed to the use of nuclear weapons as part of a missile defense system. Commenters also expressed concern that another country could use a nuclear weapon to defeat the BMDS.

Examples. “Any kind of using of Nuclear weapons in this Beautiful must be abondoned [sic.] and use such things in the proper use for providing electricity.” (DC_E0010), “The planet, the human race, all of life on this unique place called Earth cannot survive one

country's global dominance from space or the use of nuclear weapons from anywhere." (DC_E0055), "We do not need any nuclear missile system." (DC_E0061)

Response. The MDA has no plans to include nuclear material as part of the BMDS; therefore the PEIS does not consider the use of nuclear material or weapons as part of the BMDS. This PEIS does not address issues related to DoD threat assessment policy or the technological feasibility of missile defense design. Therefore comments regarding opposition to use of nuclear weapons or the technological feasibility of defeating a threat nuclear warhead were determined to be outside the scope of the environmental analysis in the PEIS.

K.3.6 BMDS could be used as an Offensive Weapons System

Summary. Several commenters expressed concern that the BMDS would not be used as a defensive system but would be used as an offensive system. These commenters expressed beliefs both that the BMDS would become a first strike system and also that other countries would see the BMDS as an offensive system and a threat to their own security.

Examples. "To be truthful about the program, it is essentially an OFFENSIVE system, in every sense of the word." (DC_E0016), "Other nations are aware that the conversion of these weapons from reactive to proactive is a simple one." (DC_E0054)

Response. BMDS weapons are described as defensive system components that could be used to destroy threat missiles. Statements including those suggesting the use of BMDS weapons components for other purposes are the opinion of the commenter and thus are considered outside of the scope of the BMDS PEIS.

K.3.7 "Voting" for No Action Alternative

Summary. Many commenters stated that they were in favor of or supported the No Action Alternative identified in the Draft BMDS PEIS.

Examples. "WE FAVOR THE 'NO ACTION' ALTERNATIVE!!!!!!" (DC_E0006), "I support the "**No Action**" option--the 3rd of 3 possible options." (DC_E0033), "It is in the opinion of many with which I've conferred to submit a No Action Alternative." (DC_E0093)

Response. The CEQ's September 2002 report on Comment Received on the NEPA Task Force stated "It is important to recognize that the consideration of public comment is not a vote-counting process in which the outcome is determined by the majority opinion. Relative depth of feeling and interest among he public can serve to provide a general context for decision-making. However, it is the appropriateness, specificity, and factual accuracy of comment content that serves to provide the basis for modifications to

planning documents and decisions. Further, because respondents are self-selected, they do not constitute a random or representative public sample." The comment period for the Draft PEIS does not encompass a voting process for the alternatives. Therefore, these comments do not require a substantive response.

K.3.8 "Voting" for Alternative 1

Summary. Commenter stated that they were in favor of developing the BMDS as described under Alternative 1.

Example. "please take plan 1 astrhe best fopr a stable defence system" [sic.] (DC_E0065)

Response. Please see response to K.3.7.

K.3.9 Administrative

Summary. Several commenters submitted inquiries via e-mail or phone for administrative requests. Some of these commenters requested hard copies of the Draft BMDS PEIS. Other commenters requested additional information about the location of public hearings or whether the comment period had been extended.

Examples. "Please send me a copy by air mail if you have not already done so." (DC_E0001), "I would like to have a hard copy of the 'Ballistic Missile Defense System Draft Programmatic Environmental Impact Statement' (1 September 2004) sent to me as soon as possible- by the fastest shipping method." (DC_E0002), "I would definitely be interested in going to the hearing." (DC_E0028)

Response. Requests for alternate means of reviewing the Draft BMDS PEIS were accommodated. Responses were provided to individuals requesting additional information about the location of public hearings and the scheduled closure of the public comment period. While these comments were noted for the administrative record they do not require a substantive reply in this PEIS.

K.3.10 BMDS as a Technology Will Not Work

Summary. Several commenters expressed their belief that the technologies used as part of the BMDS would not be effective against threat missiles. Some of these commenters stated that additional realistic testing should be conducted prior to making a decision to deploy the BMDS.

Examples. "With its questionable record so far in testing, MDA, which MUST work nearly perfectly all the time to not only be effective, but safe, should not go forward." (DC_E0019), "I have read about the total unfeasibility of this program. The precision in

timing and location needed in order to intercept a missile makes this an unrealistic program, especially considering the outrageous costs of it." (DC_E0050), "There will be a "phase lag" between the time the modified software can be developed and the time it can be installed and tested; the requirement for the continual upgrading of software alone makes it unlikely that the system can be considered operational any time soon." (DC_E0076), ""A defense that does not work against a threat that does not exist"" (DC_E0077)

Response. This PEIS does not address issues related to DoD threat assessment policy or the technological feasibility of missile defense design. These comments regarding the technological feasibility of defeating threat missiles are the opinion of the commenter, were determined to be outside the scope of the BMDS PEIS and therefore do not require a substantive response. MDA has considered the environmental impacts of system integration flight testing in this PEIS. This testing would help MDA fine tune the various systems components of the BMDS and continue to identify additional functional capabilities needed to assure the security and efficacy of the system. However, the President made the decision to deploy a limited defensive capability to ensure the safety and security of the U.S. homeland while the system was being further developed and tested. Also, because the BMDS is a spirally developed defensive system there may never be the ultimate deployment of a single architecture or even of a set of system architectures. Continuous improvement, technology development, and testing are critical to MDA's development of the BMDS.

K.3.11 BMDS Encourages Terrorism, Threatens Global Stability, and Perceived as Threat by Other Nations

Summary. Several commenters expressed that the development of a BMDS would encourage those who wish the U.S. harm to resort to terrorist activities in lieu of using missiles. Some concerns were raised that the BMDS does not address the current threat against the U.S. In addition, some commenters expressed that the BMDS would lead to global instability.

Examples. "If it works, or is suspected by potential antagonists to possibly work, their response will be twofold. First, they will multiply offensive missiles, ratcheting up the catastrophically expensive arms race. Second and more importantly, they will divert their energies to produce sub-radar cruise missiles and, worse, divert their energies to smuggle WMD across our borders, weapons with no return addresses and zero warning time." (DC_E0007), "Star Wars will breed hostility to those nations implementing it and to those who "host" the stations needed for the program to run (e.g. Fylingdales in Yorkshire, UK) - this is not welcome when we want to encourage peace, not war" (DC_E0017), "It is an insane response to security concerns and will make things more unstable." (DC_E0055)

Response. These types of statements the opinion of the commenter and thus are not appropriately addressed in an environmental analysis. Therefore, comments concerning the potential effect of the BMDS on terrorism or global stability were determined to be outside the scope of the BMDS PEIS and do not require a substantive reply.

K.3.12 Opposed to Weapons in Space or "Star Wars"

Summary. Several commenters expressed that they were opposed to deploying weapons in space. Some commenters encouraged space to be used only for peaceful purposes including space exploration and commercial applications.

Examples. "Space should never be militarized." (DC_E0011), "No weapons in space!" (DC_E0024), "I support the "No Action" alternative to missile defense systems, especially those that would utilize space." (DC_E0036), "Please stop the militarization of space now." (DC_E0038), "The planet, the human race, all of life on this unique place called Earth cannot survive one country's global dominance from space or the use of nuclear weapons from anywhere. I fear this is simply another scheme to make a few people rich -- the corporations who get the contracts, the corporations who benefit from mining the moon." (DC_E0055)

Response. Alternative 1 would not include the use of space-based weapons while Alternative 2 would include the use of weapons from space-based platforms. While this PEIS considered two implementing alternatives for the BMDS, this PEIS performed an environmental analysis, not a policy analysis of the alternatives. The comments that were collectively summarized and grouped as *"Opposed to Weapons in Space"* were comments that expressed a philosophy, value, or opposition to an action. These comments were not substantive comments on the scope of the *environmental analysis* in this PEIS regarding the use of space-based weapons but rather statements against the *policy* of using space-based weapons. These comments appear to fit within the definition provided for non-substantive comments, i.e., comments that express a philosophy, value, or support or opposition for an action; therefore, it would appear to be appropriate to include them in this grouping. These types of issues are not part of the decision to be made in this environmental analysis. Therefore, these comments were determined not to require a substantive reply.

Other commenters may have provided substantive comments on the use of space-based platforms either as they relate to debris production or other issues of concern. These comments will be addressed as part of Section K.4 of this Appendix.

K.3.13 BMDS Does Not Defend Against a Realistic Threat or Provide Safety for the U.S.

Summary. Several commenters expressed that the development of a BMDS would not defend against a realistic threat or provide safety for the U.S.

Examples. "The prospect of having weapons in space threatening anyone on earth will not enhance our security, but rather further destabilize our relations with other nations…" (DC_E0039), "Furthermore, the construction of such a system is liable to increase the danger to our own country by goading potential enemies to build bigger and better missile systems of their own." (DC_E0096), "The proposed system will promote a false sense of security…" (DC_PHO0027), "…[the BMDS] would not offer any protection for a more likely sea-platform launched attack." (DC_E0180), "Anyone serious about protecting the United States, not to mention other people in the world, would be making some effort to reduce the global spread of weapons, especially these weapons of mass destruction which don't even have a real world threat against which to defend." (DC_E0182)

Response. These types of statements are the opinion of the commenter and are thus not appropriately addressed in an environmental analysis. Therefore, comments concerning the ability of the BMDS to defend against a realistic threat or provide safety for the U.S. were determined to be outside the scope of the BMDS PEIS and do not require a s

K.3.14 Realistic Testing Should be Conducted Prior to BMDS Deployment

Summary. Several commenters expressed that realistic testing of BMDS components should be conducted prior to deployment of the BMDS.

Examples. "…should the decision be made to pursue the program that a more realistic testing program be developed and carried out as a part of the development program." (DC_E0156) "I urge everyone concerned to halt all missile defense system deployment until realistic testing is completed and the system is demonstrated to be very successful under realistic conditions, including likely countermeasures such as decoy targets." (DC_E0440) "The worse aspect is the rush to deployment before components have been tested fully." (DC_M0001)

Response. This PEIS considers the environmental impacts from possible realistic testing scenarios that could be used to test the BMDS. However, this environmental analysis is not the appropriate venue to determine the outcome of testing and thus to determine when or how to deploy an integrated BMDS. Therefore, comments concerning deployment of the BMDS only after successful realistic testing were determined to be outside of the scope of the BMDS PEIS and do not require a substantive reply.

K.3.15 Generic Comments on Environmental Issues

Summary. Several commenters presented general concerns about the potential environmental impacts associated with the development, testing, deployment, and decommissioning of the BMDS. Comments that were identified under this category tended to be statements of opinion and were not supported by scientific evidence or were not specific comments on the analysis presented in the PEIS.

Examples. “In considering the Environmental Impact of the proposed BMD system, the PEIS should address the full extent of possible environmental impacts on our planet and the proposed surrounding outer space intended field of operations” (DC_E0424), “Even if MD does work, the likely health and environmental consequences of the fallout from an intercepted missile (potentially with a nuclear, biological or chemical warhead) being dispersed over populated areas render the system unacceptable.” (DC_F0007), “Deployment of such a system threatens a new nuclear arms race, puts the global environment at risk, and does not improve the security of the United States.” (DC_E0343) “Deployment of the Bush administration’s proposed missile defense system threatens the global environment.” (DC_M7903)

Response. Many of these general or non-specific environmental issues are considered in the PEIS. Some resource areas including Cultural Resources, Environmental Justice, Land Use, Socioeconomics, Utilities, and Visual Resources are more appropriately considered in site-specific environmental documentation. Each of these was discussed regarding methodology and thresholds for significance to provide a “roadmap” for performing future site-specific analyses tiering from the PEIS. The following resource areas were considered in the PEIS: Air Quality, Airspace, Biological Resources, Geology and Soils, Hazardous Materials and Hazardous Waste, Health and Safety, Noise, Transportation, Water Resources, and Orbital Debris.

The PEIS analyzes the environmental impacts of the implementation of the BMDS under Alternative 1 in Section 4.1.1, this includes the use of weapons, sensors, C2BMC, and support assets for all of the resource areas described above. The environmental impacts of Test Integration under Alternative 1 are analyzed in Section 4.1.2. The impacts of activities at Locations Outside the Continental U.S. are discussed in Section 4.1.3. The cumulative impacts associated with Alternative 1 are considered in Section 4.1.4. The environmental impacts associated with Alternative 2 are addressed in Sections 4.2.1 Impacts Analysis, 4.2.2 Test Integration, and 4.2.3 Cumulative Impacts. The impacts of the No Action Alternative are addressed in Section 4.3.

K.3.16 “Voting” for Alternative 2

Summary. Commenter indicated support for Alternative 2 as presented in the BMDS PEIS.

Examples. “I would encourage our government to continue research and development of a space based weapons system or systems based on the needs of the United States as outlined by the Joint Chiefs of Staff.” (DC_E0353)

Response. Please see response to K.3.7.

K.3.17 In Favor of BMDS

Summary. A few commenters stated that they were in favor of the testing and/or development of missile defense technologies including those proposed for the BMDS.

Examples. "I am writing today to support the the [sic.] deployment of the missile defense system." (DC_M7808), "I believe we should have a limited missle [sic.] defense system capable of defending the USA and our allies from a small scale missle [sic.] attack (50 or fewer missles [sic.]." (DC_M7712) "I am writing today to support the missle [sic.] defense system." (DC_M7739), "Therefore, I fully support the Bush Administration's plans for missile defense." (DC_M7843)

Response. As stated in Section 1.2 of the Draft BMDS PEIS, on January 2, 2002, Secretary of Defense Rumsfeld issued a directive to the DoD to establish a single development program for all the work needed to design, develop, and test elements of an integrated BMDS that would operate under a newly titled MDA. Therefore, it has been determined that a BMDS should be developed. This PEIS considers the environmental impacts of various implementing alternatives for such a system. Therefore, comments expressing a favorable opinion of the BMDS and other related policy issues were determined to be outside the scope of this environmental analysis.

K.3.18 Miscellaneous Issues or Topics

Summary. Several commenters provided comments that were determined to be on issues or topics that did not pertain to the BMDS. These comments were determined to be out of scope. Examples of these comments are provided below.

Examples. "Likewise destroying the population of the earth through AIDS Ebola, SARS, Anthrax, Chemtrails, lethal drugs, deadly vaccines programmes, fluoridation of water, etc should also be halted forthwith." (DE_E0198), "…We have programs now that have technology that can actually change the way that we think. We have to choose that. It's a choice we have to make. But we can actually change from a victim mentality to a very powerful mentality in taking responsible for our actions. This kind of technology is also available in Israel and practiced on a regular basis all over the world through a program called Landmark Education. There is also a program called the HeartMath that teaches thinking through the heart, as opposed to strictly through the head…." (DC_PHO0034) "…In a little joke on the refrigerator where a man is standing on stage and he's asked to play a concerto. He says, "Don't make me come down there" to the audience. I'm going to go down there. I don't know how successful I will be. But maybe if everybody who lives in Sacramento will call Mr. Mort Salisman and leave messages on his machine and ask him why nobody was here and why Channel 3 and Channel 10 didn't come either. I don't know what they're doing but I know -- I don't know. I don't think so because they checked the list…." (DC_PHO0035) "…The World's first thermonuclear

device utilizing hydrogen fusion, a project code-names Mike, was detonated on Enewetak in 1952…." (DC_PHW0012)

Response. Because the subject matter of these comments did not pertain to the BMDS they were determined to be out of scope or non-substantive and are therefore not considered further.

K.4 In Scope Comment Documents

Comment documents that contained substantive comments that were determined to relate to the scope of this PEIS were identified.[3] These comment documents are reproduced in Section K.4.1. In general, comments that addressed the resource areas analyzed in the Draft BMDS PEIS, feasible alternatives, relevant laws and regulations, and specific comments relating to the impacts analysis, were considered in scope. Responses to in scope comments are provided in Section K.4.2. Section K.4.2 includes the comment document number and sequential number of the comment, the resource area addressed by the comment, the text of the comment, and MDA's response. Where appropriate, revisions to the Final BMDS PEIS were made in response to these comments. Note that the names and addresses have been removed from the reproductions to protect the privacy of the commenters.

K.4.1 Reproductions of Comment Documents Containing In Scope Comments

[3] Note: responses to comments from Federal agencies are provided in Section K.5 of this Appendix.

Subject: MDA BMDS PEIS

1) The new Star Wars program as outlined in the PEIS will be destabilizing thus creating new momentum to move the deadly and dangerous arms race into the heavens. This will create more global instability and nuclear materials accumulation and contamination around the world.

2) Testing and deployment of weapons in space will create massive amounts of new space debris making the environment of space even more contaminated and thus unavailable for future space flight.

3) This new Star Wars plan will be extraordinarily expensive requiring massive cuts in environmental clean-up of other problems, with the many drastic environmental impacts that would cause.

4) The likely use of nuclear power for eventual space-based weapons would be a long term environmental disaster.

5) Space-based weapons, described in the PEIS as being "defensive", could easily serve an offensive purpose as outlined in the Space Command's Vision for 2020 that says the U.S. will "deny" other nations the use of space.

6) Toxic rocket exhaust pollution is now contaminating the Earth and punching a hole in the ozone layer. This plan would dramatically expand these polluting launches.

7) Offensive tactics such as new decoys, maneuvering warheads, concurrent high altitude nuclear bursts to disable sensors, all make the probability of complete success of the BM defense almost zero.

8) Unless the offensive missiles are sensed on launch and destroyed during boost, the dirty bomb effects will rain on the targets anyway; and the proposed system is not designed to intercept during boost.

9) Other offense delivery mechanisms like suitcases in a shipping container, were not addressed, and would probably be more effective.

DC_E0030

10) The environmental effects of the X-band radar upon people and birds have not been thoroughly studied.

11) The conservative cultist and Republican affectionado, Sun Myong Moon, has helped the North Koreans obtain submarines; so the launch points and trajectories for which the system was planned can be circumvented, yielding the system worthless.

12) Shifting alliances and politics may make Russia, China, India, Pakistan, or any of several middle east countries more of a threat than North Korea. Alternatives to world-ending war mistakes are needed, not infinite arms building around the world.

13) For all these reasons I support the "No Action Alternative."

Dwight Rousu

I would rather live with uncertainty than with answers that are wrong. (from Feynman)

Subject: public comments on national security utility of ballistic missile defense system

Dear Sir / Madam

I request that the following be added to the record of public comments as part of the initial assessment of the feasibility of the proposed ballistic missile defense system currently under consideration by the present (Bush) administration.

My credentials are that I have a Bachelors in Electronics and a PhD in physics. I spent 10 years in automatic image analysis, and have authored several publications and some patents in that field - in addition to papers I have authored in physics. A large part of that 10 years was spent working for a defense company, some of which on a DARPA project, developing automatic image analysis with potential applications for intelligent weapons guidance. I was awarded a research scholarship at Princeton University, and currently work for a non-profit research institute in Austin, Texas.

In the following, the term `image' applies to any time-evolving 2D array of data captured by optical, infra-red, and microwave sensors.

Very briefly, it is my perception that the state of the art in automatic image analysis is such that reliable object recognition is possible only in well-controlled environments wherein the quiescent illumination, the clutter, and preferably the orientation of the target object are under control. These environmental constraints obviously cannot be imposed on a ballistic missile defense system, and therefore one should be very skeptical of claims that enemy missiles can be reliably identified. To the extent that the proposed system depends on automatic detection of enemy missiles, it is very unlikely that it will be reliable, given the present state of the art.

No doubt more reliable methods will be developed in future. But I urge an honest evaluation of the current test data, and realistic assessment of possible future improvements, uncorrupted by commercial and political influences.

Yours Sincerely,

Dr. Michael Ibison

Subject: Public Comment on Space based missle defense system

To whom it may concern:
My name is Arne Soderman. I'm working and living in Portland, OR. After reviewing this plan for a space-based missle defense system I have criticisms that are not remedied by any option you've given the public. Of the three choices, I am compelled to support the "No Action (#3)", as it is the least destructive to the environment.

Acquiring the necessary materials, construction, and especially deployment of these systems into space are uneqivocally harmful. Rockets emitting a plethora of chemicals, continue to punch holes in our thinning ozone layer; and that which falls to the earth poisons our groundwater and rivers (perchlorate). Intensifying this for enemies non-existant (for no good reason) would be pointless destruction.
Larger objects that return to earth, or stay in orbit present problems as deadly space litter travelling at thousands of miles per hour, or hundreds as they strike the earth. Space litter has already killed (when Mir was left to gravity) and more only increases the chances of the loss of human, animal, and plant life as objects fall where they may.

The detonation of these weapons destroys the environment in a way that makes the above concerns seem silly. Nuclear winter is the end of human kind.
When we threaten others with nuclear devices, we are responsible for the nuclear devices that they come to possess. When we detonate first, that which happens as a result is also our responsibility. This missle defense system is advancing the world towards nuclear proliferation. We should abandon all weapons nuclear, and return to the United Nations Disarmament Treaty process. I can't support anything but a True "NO ACTION".

sincerely
Arne Soderman

Subject: comments on the draft BMDS PEIS

5 Nov. 2004

via E-mail to: mda.bmds.peis@icfconsulting.com MDA BMDS PEIS c/o ICF Consulting 9300 Lee Highway Fairfax, VA 22031

Below are my comments on the draft Programmatic EIS (PEIS) for the Ballistic Missile Defense System (BMDS). Some of the PEIS deficiencies could be fixed by changes to the draft but this document comes so late in BMDS development and testing that it is largely irrelevant. Section 1.2 shows that environmental analyses have already been done for most components; notable exceptions are Aegis BMD and space-based weapons.
Development and testing of most components are well underway and decisions about initial deployment of GBI's and Aegis BMD ships have been made. The spiral development process which, according to the PEIS (page ES-7) allows MDA to "consider deployment of a missile defense system that has no specified final architecture and no set of operational requirements,"
seems to preclude any meaningful assessment. The PEIS could make a useful contribution by analyzing how to judge the effectiveness of a system with no operational requirements.

Another major general deficiency is that the No Action alternative is not considered seriously. It is asserted on page 2-67 that it "would not meet the purpose of or need for the proposed action or the specific direction of the President and the U.S. Congress." Footnote 19 on page
1-6 quotes the part of the 1999 Missile Defense Act which declares a policy to "deploy as soon as is technologically possible an effective NMD system." It is noted on page 1-6 that Pres. Clinton decided in Sept. 2000 not to authorize deployment of an NMD system for reasons including technical uncertainties and unsuccessful flight tests. Two GAO reports in
2003 and a Union of Concerned Scientists report Technical Realities in May
2004 raise serious questions about the readiness for deployment of current NMD components. Therefore, it seems that the No Action alternative (which was essentially U.S. policy until 2002) is preferable until one can demonstrate that an "effective" NMD is "technologically possible." The most recent NMD intercept attempt failed on 11 Dec. 2002, six days before Pres. Bush announced that the U.S. would deploy an initial NMD system. The test results so far and independent analyses suggest that it is at least questionable whether an effective NMD system is possible.

Detailed comments follow.

1) The PEIS should give quantitative information on the reliabilities of the boosters to be used to launch targets for BMDS tests. I noted in my scoping comment (See first comment on page B-15 of the draft PEIS.) that I had asked for this information in my comments on the 1994 BMD draft PEIS and that the response was inadequate for any meaningful assessment of the risks from launch failures. This information is especially important to include in the PEIS because the same target boosters are used in various test programs and because the information has not been included in previous environmental analyses. I noted in my comments on the 2003 GMD ETR draft EIS that an analysis of Minuteman test launches found a rate of severe failures of 15% and that the Strategic Target System has had one serious failure
(9 Nov. 2001 launch from Kodiak) in five launches. Including my scoping comment in exhibit B-9 as a health and safety issue seems to imply that this aspect should be analyzed in the PEIS. At the 26 Oct. public meeting in Honolulu, I was assured that including booster reliability information would be considered.

2) The PEIS should examine in detail treaty compliance of various BMDS tests. The draft

PEIS has no discussion of INF Treaty restrictions on long-range air-launched and sea-launched targets or START Treaty restrictions on sea-launched targets even though I raised this issue in my scoping comments. (See fourth comment on page B-15.) The GMD ETR EIS did not consider treaty compliance despite the fact that previous analyses
(1994 TMD ETR EIS and 1998 TMD ETR Draft Supplemental EIS) did consider this issue. The 1994 TMD ETR EIS refers to the INF treaty prohibition of air-launched and sea-launched missiles with ranges between 500 and 5,500 kilometers. The 1998 TMD ETR DSEIS notes that the START treaty prohibits launches from sea-based platforms and that launches from ships are restricted to ranges less than 600 kilometers. If subsequent compliance reviews of air-launched and sea-launched targets have been done, they should be discussed in the PEIS and references to them should be cited.
I was assured at the 26 Oct. meeting in Honolulu that this would be considered.

3) The PEIS discussion of cumulative impacts in section 4.1.4 and Appendix I has no details about the location, schedule, and specific missiles to be used for the estimated 515 launches from 2004 to 2014. This is important because there are annual limits on the numbers of launches at the Pacific Missile Range Facility (PMRF), Kodiak, and Vandenberg AFB, as noted in the GMD ETR EIS. The GMD ETR EIS estimated 10 launches per year so the PEIS needs to give some details about the additional 415 launches. Some information about future launches for tests of some BMDS components is provided in Appendix D. However, there are no estimates for Aegis BMD tests and only vague estimates for GMD tests. For example, it is stated on page D-25 that, "GMD test plans include a number of missile-launches (interceptors and/or targets) from each launch facility per year." The PEIS should also include impacts of test launches of offensive missiles.
For example, tests of the Trident D5 are reported to be planned near PMRF in 2005.

4) Page D-15 of the PEIS contains misleading information about previous NEPA analyses related to Aegis BMD. It cites the 1998 PMRF Enhanced Capability EIS as a supporting NEPA analysis. In fact, this EIS explicitly excluded the Navy Theater-Wide System (now called Aegis BMD) from evaluation. No subsequent environmental analysis has been done even though Aegis-LEAP tests have been done near PMRF. The PEIS should indicate when environmental analyses of this system will be done. Press reports have indicated that 20 sea-based midcourse interceptors are scheduled for deployment in 2005. The PEIS states on page D-19 that three Aegis BMD cruisers and 15 Aegis BMD destroyers would be available for deployment at the end of Block 2004.

5) The PEIS has no discussion of the unresolved safety issues involving Strategic Target System and THAAD launches at PMRF which I noted in my scoping comments (second comment on page B-15). No detailed hazard areas have been shown for Strategic Target System launches at azimuths other than 280 degrees. Similarly, no diagrams showing the THAAD hazard area were given in the 2002 THAAD EA and no detailed analysis was cited to justify the reduction in the hazard area radius from 20,000 feet in the
1998 PMRF EIS to 10,000 feet in the THAAD EA. There can be no meaningful public evaluation of the risks of such launches without this information.

6) The PEIS contains a short discussion of future laser weapon systems (page F-7) and the Tactical High Energy Laser (page F-9). It notes that testing of a laser demonstrator began in 2000. The PEIS should review these tests and testing plans for other high-power laser weapons and other directed-energy weapons. An article in the 18 Dec. 2002 Jane's Defence Weekly indicated that a megawatt-class free-electron laser could be tested at PMRF in two to three years.

7) In addition to "hit-to-kill" interceptors and directed-energy weapons, there have been reports that interceptors armed with nuclear weapons are also being considered for missile defenses. The PEIS should indicate what research and development work is being planned for such weapons as part of the Advanced Systems in Appendix F. How would such systems be tested without violating the Limited Test Ban Treaty and the Comprehensive Test Ban Treaty?

8) In 2002 the Defense Dept. announced that it would classify details about missile defense tests that had previously been public information. How can the public and independent technical analysts assess the impacts of tests and judge the effectiveness of BMDS components if this information is unavailable? Similarly, how can one estimate the impacts of entirely secret programs?

9) There are egregious errors in Exhibit 4-11 on page 4-102. There is an addition error

in the line for HCl emissions. The more serious error is that the total emissions of 115 kilograms for the representative interceptor is too small by a factor exceeding 100. Table 4.1.1-8 of the
2003 GMD ETR Final EIS gives total stage 1 exhaust emissions of greater than 15,000 kilograms. The GBI analyzed in that EIS had a total propellant mass of 19,767 kilograms of which 15,069 was in stage 1. The PEIS notes on page D-20 that each GBI may contain up to 20,500 kilograms of solid propellant. Exhibit 4-11 should be corrected; the information for BMDS launches in Exhibits 4-13, 4-14, and 4-15 may need correction if it is based on the interceptor data in Exhibit 4-11.

10) The brief history of U.S. missile defense activities in section 1.2 excludes any mention of critical technical analyses of components and testing of them. For example, the 1998 report of the Pentagon panel headed by Gen. Welch characterized the inadequate preparation for flight tests as a "rush to failure." Two GAO reports in 2003 (GAO-03-441 and GAO-03-600 available at www.gao.gov) questioned the adequacy of testing and readiness for NMD deployment. The May 2004 report Technical Realities (available at www.ucsusa.org/global_security/missile_defense/index.cfm)
by the Union of Concerned Scientists provided a critical analysis of the NMD system being deployed. It is noted on page 1-7 that Pres. Bush's
17 Dec. 2002 decision to deploy an initial defense capability followed "continued test bed development and successful flight test activities."
It should be added that this decision followed by six days a test failure and that the test record so far is five intercepts in eight attempts.

11) The brief history of the Lightweight Exoatmospheric Projectile (LEAP) program on page D-17 states that tests in the early 1990's showed that LEAP "could be integrated into a sea-based tactical missile for ballistic missile defense." In fact there were no successful intercepts in five attempts in these tests. Two successful Aegis LEAP intercept tests in 2002 are described but there is no mention of the intercept failure on 18 June 2003.
The Aegis LEAP test record so far is four intercepts in five attempts.

12) It is stated on page D-40 that there were eleven THAAD flight tests in the 1990's and that, "Upon successful intercept, the THAAD program began planning to validate the performance capability and overall effectiveness of the THAAD element, flights tests, and intercepts of target missile launches over more realistic distances..." Of the eight intercept attempts in the 1990's tests, there were only two hits.

13) The example test scenario on page 2-13 involves use of the Cobra Dane radar. However, the August 2003 GAO report GAO-03-600 noted that there were no plans to test this radar using BMDS targets. Are such tests now planned in the next ten years?

14) The details of integrated flight test events are characterized as "only conceptual at this time" on page 2-50. Some test scenarios examined in the
2003 GMD ETR EIS had jet routes between Hawaii and the West Coast crossing the target and interceptor debris areas. What details about these tests will be made available for public evaluation?

15) Section D.2 has a brief discussion of land-based and sea-based Kinetic Energy Interceptors (KEI) for use as possible components of a boost-phase defense. It should be noted that a study of possible boost-phase defenses -- including surface-based and space-based KEI -- found that they would have limited capability against liquid-fueled ICBMs and were unlikely to be practical against solid-fueled ICBMs. This study was done by an American Physical Society study group and was released in July 2003. It is available at
www.aps.org/public_affairs/popa/reports/nmd03.cfm

Subject: PEIS Comments Corrected Version Please Use Only This Copy

Note from Laurence H. Ebersole: This is my corrected comment. Please disregard the previous one sent today. I was misinformed about Alternative Three being a no project alternative. Rather, I want to point out that the entire project is Flawed and should be Halted (alternative three merely continues the existing programs without halting them).

Laurence H. Ebersole

November 8, 2004

Dear Consultants:

RE: Comment on Ballistic Missile Defense System.

As I understand the situation, public comments are invited to help with the review of the proposed, Ballistic Missile 'Defense' System.

I believe that halting the project is the best option.

My concerns are both substantive and technical. First my substantive concerns.

I) I think, the World Court Decision of 1996, along with customary international law, and binding treaty, all require that the United State's along with all stated nuclear powers, disarm nuclear weapons; not build more, or make technological shields against the use of nuclear weapons. Goals, and specifics for this nuclear disarmament can be resolved without further delay, since the ground work is already part of the history of arms control, and disarmament agreements.

Therefore, to implement, for instance, Article IV of the Nuclear Non Proliferation Treaty, and to completely ratify the Comprehensive Test Ban Treaty, are a best shield against nuclear weapons ever being used, or the thereat of use of these weapons. Please remind the proponents of this weapons system to uphold these international agreements. Please do not violate these agreements by constructing, planning to construct, the proposed missile 'defense' systems.

II) Technologically, the concept of a missile defense is flawed for an Anti-Missile Missile System. The system can be used as a first strike system, and be viewed this way, thus, contribute to weapons proliferation. The system will drain public funds further away from humane uses like higher education, social rehabilitation, environmental cleanup, child care, health care -- the economic, social, and cultural

DC_E0179

human rights asserted in the Universal Declaration of Human Rights (Articles 23 & 25 among others). The system is not needed and is a "pork" program for the profits of the weapons makers. The system contributes to pollution and greater atmospheric ozone destruction, at a time when the impacts of global warming are reasons to be concerned. The system involves radionuclide's and nuclear elements which are toxic, and themselves can burn and potentially causes public health problems.

Conclusion: Please implement a Halt to all further development to design, building, planning, deployment, of a first strike weapons system known as the Anti Missile Missile System (the ballistic missile 'defense' system).

Yours Sincerely

Laurence H. Ebersole

Subject: PEIS on the Balistic Missile Defense System: Public comment

Hanford Watch
November 8, 2004

I am commenting on behalf of our organization on the Alternatives being proposed by the government on continuing on with the building of the BMDS as well as choosing from among your proposed options.

We are against all of the proposed alternatives, including the No Action Alternative for the following reasons.

First, this program so far as produced few results for the incredible amount of taxpayer dollars that have been spent since Reagan's Presidency. Much of the thinking behind this pork project has been based on flawed premises and illusions of grandeur by the people who are getting rich off the scheme.

Second, this PEIS is supposed to show the impacts of this project on the environment. According to your charts the impacts will be great on our water, which is becoming a scarce resource (that is, clean water, drinkable water), on our air which is already a hazard to human health for all living creatures and in particular for the children of the planet--the future generation and on the earth in the places it is being built. There will be horrendous impacts from the debris that is left in space and will eventually affect the planet It will impact the oceans and the species that inhabit the ocean. Nuclear power will be used in this project and we to date and in the future have no way to protect ourselves from the extreme and long-lasting hazards of the waste. Yucca Mountain and WIPP will hold only a small portion of all the commercial and defense waste that exists now, not to mention all that will be created in the future by programs of the defense department. It will further degrade the land which sustains us.

Third, this project will further destabilize the globe, which seems to be part of the intent. This program will not save us from terrorists who have no need of the sophisticated weapons that this "shield" is to theoretically protect us from. This program fosters an arms race as well as weapons proliferation rather than deterring other nations or "enemies" from competing with us. . It is part of the double standard by which our government and the defense department operate, only making the world a far less safe place. The real intent of the program according to some of your own documents is to take control of the world by space, land, sea and air as the gulf widens between "the haves and the have not's"--a gamut of policies planned by a group of the administration that is in power at this time.

Finally, this project has and will continue to squander our precious resources, especially our money, our tax dollars while education systems flounder, health care becomes a luxury only for the rich (while we all have our health placed in more jeopardy by such projects. We are living under an incredible deficit which our children will not even be able to make a dent in and will continue on the road to becoming a third world country.

DC_E0186

To continue on with this project as would be the case even under the "no action alternative" is unconscionable. We believe that even if you were to re-do the PEIS, there would be no reasonable alternative other than shutting down the project and calling it the loss it already is.

Sincerely,

Paige Knight, President

It is my understanding that Alternative 3 means "no change" so that all programs continue as planned. This is not acceptable. The statement must be rewritten to allow for a true "no action" choice....meaning NO R&D or Production of the missile defense program, no weapons in space!

Rosalie Paul, Georgetown, Maine

The PEIS considers three options:

Alternative 1, missile defenses without space-based weapons.
Alternative 2, missile defenses with space-based weapons.

Alternative 3, no action.

Subject: Missile Defense- Rewrite entire PEIS, please. stop funding Star WArs

The PEIS must be rewritten, because the "No action" alternative is insufficient. The most appropriate choice is to stop all funding of Star Wars Missile defense.

The extraordinary expense of this program is inexcusable, and should be discontinued. The entire program will do far more harm to the entire world and US security than if it were discontinued.

To develop missile defense at this level will move the arms race to space, and will destabilize an already unstable world.

The use of nuclear power to propel the missiles and the likely debris we would be releasing into space is environmentally, a disaster.

I want no more of my tax dollars to support this foolish program. Please rewrite the PEIS to allow the sanest alternative- scrapping this program entirely- to be a choice. The best choice.

Thank you.

Sincerely,

Will Fudeman

Subject: Comments of Star Wars

To whom it may concern:

The night sky is a beautiful sight. It brings a sense of wonder and awe for a universe our species is only beginning to know. There is so much we don't know, but one thing we better learn quick is how to live in peace. Going ahead with Bush's Star Wars plan brings war and nuclear power into Outer Space. It makes other nation-states afraid of what the US might do. It could start another Cold War. Anyone with a heart and knowledge of science knows that bombs in Outer Space is a violation of the life force.

Deployment of these new weapons litters the atmosphere with space junk, just what we don't need in a world that already doesn't know how to recycle most of its rubbish. When people around the planet are starving and homeless, why spend an extraordinarily amount of money on a program that helps nobody? The flumes from the fuels only comes back to Earth and makes us sick. Isn't it time we wised up and stopped killing ourselves?

For all these reasons I believe the "No Action Alternative" is insufficient and the entire PEIS should be rewritten.

Subject: NOT ACCEPTABLE!

None of the three options for PEIS is acceptable! The third is the most dangerous because it is so deceptive, meaning "business as usual." Let's scrap this entire frivilous program and get on with the vital business of remediation of the mistakes of the past four years and prevention of more of the same during the second Bush administration.

To Whom It May Concern,
I am writing in opposition to the three options of the MDA BMDS PEIS, including the No Action option, since it is in reality not a true No Action as it includes continued development of interceptors.
I urge you to revise these options with more concern for the environmental damages that will result from these actions.
Thank you.

Subject: why no?

Stop the madness!!! We do not need weapons in space. That would only create an entirely new arms race. If selling weapons is all one cares about this is the goal. It has been agreed internationally to use the heavens for only peaceful endeavors. Common sense reveals many problems here on earth that need attending to, and with our government already overspent it makes no sense. the biggest concern is that this "defense" system is just another offensive weapon, adding to our already illegal slant toward preemtively blasting whomever we say is the criminal of the day. How do we know of this intent? because the defense missiles have failed all attempts to hit other missiles, the only answer is that someone wishes to have space-strike capability.

The"No Action Alternative" is insufficient and the entire PEIS should be rewritten.

No nukes in space!!!!!!

Paul Cunningham

Subject: Oct. 14, 2004 BMDS Draft PEIS Comments

Carolyn Heitman

October 14, 2004

Sent E-mail to: mda.bmds.peis@icfconsulting.com

Enclosed are my comments on the BMDS Draft PEIS.

The MDA did a very poor public relations job in regard to getting the word out on the availability of the Draft PEIS and on the October 2004 public hearings in what will be the affected BMDS test communities. The public cannot make comments on something they do not know exists if it is not well advertised in advance (e.g. notices in newspapers). Holding public hearings in Anchorage, Alaska when the BMDS test site is located on Kodiak Island, Alaska, and in Sacramento, California when the test site is at Vandenberg AFB near Los Angeles, showed the MDA's intent was to make it as difficult as possible for members of the public to travel to the meeting places to testify and give their comments on the Draft PEIS. The MDA put a public notice in the Kodiak Daily Mirror and sent a copy of the Draft PEIS to the Kodiak Island Borough's office only after being urged by local residents. Otherwise, local officials and community members would not have known of its existence. This repetitive MDA behavior is unacceptable.

Some of the issues I wanted to see addressed by the MDA which I listed in my June 7, 2003 comments on the Notice of Intent to Prepare a PEIS for the BMDS were:

(1) Whether or not any *low-yield nuclear material* will be used in the BMDS test systems (boosters, payloads, dummy warheads, satellites, interceptors, targets, radar systems)
(2) Whether or not any *low-yield nuclear material* will be stored at Research Development Test Sites
(3) If *depleted uranium* will be used in/on target missiles, interceptors, satellites, boosters, etc.
(4) If *depleted or spent uranium* will be stored at Research, Development Test Sites
(5) A listing of the Test Sites where target missiles will be launched to be intercepted by the Airborne Laser
(6) Include detailed information on *High-Powered Microwaves* ('Directed Energy') will be used as part of the BMDS and the environmental hazards associated with their transmission into the atmosphere and ionosphere (include human Electromagnetic Radiation (EMR) hazards)
(7) If missiles are being proposed for launch from Fort Greeley, Alaska
(8) Information on proposed BMDS launches from Poker Flats Rocket Range, Alaska

None of the above issues were clarified or answered in the Draft PEIS, so once again-- I am requesting the issues be addressed.

NOTE: Regarding Fort Greeley, Alaska-- is the MDA proposing to launch future 'interceptors' in a 'north trajectory' (or south trajectory), over Alaska native villages from that location? If so, the PEIS should list all safety drop-zones for falling booster stages and proposed trajectory launches, along with what safety steps will be taken to protect natives in their villages. Also include potential cumulative environmental damage to the tundra from falling boosters.

The MDA has never referenced or included discussion on the **INF Treaty MOU** in any previous Ea or EIS in regard to missile defense testing, nor is it discussed in the BMDS Draft PEIS. *Why not? Why is the MDA avoiding*

DC_E0319

this issue? Nor has the MDA referred to or listed the Research and Development test site locations in Alaska on the INF Treaty MOU list (e.g. Kodiak Launch Complex, Alaska and Poker Flats Rocket Range, Alaska). The MDA's avoidance of discussion on these test launch sites, leaves open the question as to whether or not *nuclear material* can and *will* be launched from these test-site locations on future targets, interceptors, boosters, dummy warheads or used in laser systems. The PEIS *should* include information on the INF Treaty, the INF Treaty MOU test locations, plus any proposed future plans to use nuclear material as part of ground-based or space-based BMDS testing. The MDA is projecting test plans up to the year 2014, so it already knows if nuclear material is part of the BMDS test system (power for space-based platforms, lasers, etc).

There has not been an environmental assessment since 2001 (that the public is aware of) regarding the reliability of the STARS missile to justify the continuation of this launch vehicle. The November 2001 STARS launch from the Kodiak Launch Complex resulted in failure (the missile 'exploded' 7 miles off Kodiak's shores after launch and the MDA attempted to cover up the accident). No public reports were released on this launch failure. The STARS missile has not been improved since the early 1990's launch failures from Kwajalein Atoll. This program should be discontinued due to its unreliability, safety hazards, and pollution to air and water.

The BMDS Draft PEIS discusses ground testing of 'portable' lasers, but does not list all the potential test sites. A September 2004 ABC news report stated a Delta Airlines pilot received an eye injury when a laser beam came through the cockpit window on his approach to the Salt Lake City, Utah airport. There have been no further reports regarding where the laser beam originated; However, it leaves open the possibility of whether some ground-based or air-based laser tests were going on at the High Energy Laser Systems Test Facility located at the White Sands Missile Range in New Mexico and the Delta Airlines pilot happened to get caught in the laser's crossfire. Utah and New Mexico are within close proximity in air miles. As stated in the Draft PEIS (Volume 1, page 4-21 thru 4-34), environmental and human health hazards would result from testing air based and ground based 'portable' lasers, which is: cancer causing chemical releases into the air and waters, potential skin burns and retina damage from laser beams and/or laser 'scatter', hazards to commercial and other aircraft, birds, plants and wildlife. "Hydrochloric acid produced as a result of the interaction between laser emissions and moisture in the air has the potential to produce impacts on biological resources, including plants and aquatic animals, and water quality" (Draft PEIS Volume 1, page 4-23). "Exhaust emissions from laser activation have the potential to harm human health." "Laser beams can cause serious health problems if they contact the skin or eyes" (Volume 1, page 4-34). The PEIS should include all proposed laser test sites including the BOA, and, what experiments will take place at each site, and the total amount of acreage needed as a safety zone. For example, will the Airborne Laser 'test fire' at targets or interceptors launched from Vandenberg AFB, Kwajalein, Kodiak Island, Fort Greeley, or Poker Flats Rocket Range, Alaska?

The Alaska Aerospace Development Corporation (a.k.a. Missile Defense Agency) has requested jurisdiction over an additional 14,000 acres of Narrow Cape '*public*' land on Kodiak Island, Alaska, over and above the 3,800 acres it already has jurisdiction over. The PEIS should include what type of BMDS testing/activity is being proposed for the Kodiak Launch Complex that would require almost 18,000 acres of public land. Since the request was made *after* the release of the July 2003 Ground-Based Midcourse Defense (GMD)-Extended Test Range FEIS, the reason for the request should have been included in the BMDS Draft PEIS.

The Draft PEIS did not give enough detail on the variations of BMDS 'Directed Energy' weapon systems in Appendix F--'Advanced Systems' (e.g. high-powered microwaves), or proposed ground-based test locations. All proposed plans should be included in the PEIS for directed energy weapons. A high-power 'electromagnetic' phased array radar network is located on Kodiak Island, Alaska, but the MDA has refused to acknowledge its existence or purpose in all previous Kodiak Launch Complex Environmental Assessments since 1999 (when the microwave system started operating). The microwave's 1.9 Mega Watts (MW) of power has the potential to be used as a BMDS weapon by turning on its high power and directing it at a target or missile, thereby disabling the target's electronics and/or 'heating' up the target and causing it to explode in flight. The U.S. Air Force has received funding for several years for its 'Directed Energy' or 'Electromagnetic Warfare' program (which includes high-powered microwave systems). It is time for the MDA to 'declassify' the program and acknowledge the Kodiak microwave and explain how it will be used in BMDS testing and the human health hazards to Kodiak Island residents from the electromagnetic radiation (EMR) when the microwave is operating.

Draft PEIS Volume 2, pages D-25, D-26 (Exhibit D-6) states Ground-Based 'Interceptors' will be launched from the Kodiak Launch Complex (KLC), Alaska. In the Fall of 2003, a press release by the MDA stated only target missiles, not interceptors would be launched from the KLC. No previously released EAs or EISs have included plans for launching interceptors from Kodiak Island.

Kodiak Launch Complex and Kodiak Island issues that should have been discussed in detail in the BMDS Draft

DC_E0319

PEIS are:

(1) Island-wide areas that will be evacuated for BMDS activity
(2) Health and Safety procedures for exposure to launch debris- especially for potentially affected populated native villages such as Old Harbor and Akhiok
(3) Doing a site-specific operating document (referred to in Volume 2, page H-13)
(4) The potential electromagnetic explosive devices, ionizing and non-ionizing radiation hazards
(5) Hazards and trajectories of interceptors
(6) Special Use Airspace and Domestic Warning Areas

'Generally, sites where activities for the proposed BMDS activities may occur are located far from towns and population centers and are surrounded by open space' (PEIS Volume 2, page H-14).
This does not apply to the Kodiak Launch Complex. The test site is located only a few miles from a populated and State of Alaska recreational area. Cabins, homes, bed and breakfast accommodations are located near the Pasagshak River, which is highly frequented by fishermen and tourist during summer months, and hunters and recreational users during the winter months. Cabins and homes are in year-around use in the winter unless the roads are impassable due to snow coverage. However, this is not expected to be a problem since the road to the launch site has to be accessible to workers (especially in preparation for an upcoming launch). The PEIS needs to discuss proposed BMDS activity on Kodiak Island in detail.

BMDS Draft PEIS Volume 2, Page D-27—Deployment; MDA proposed plans for 2004-2005 include as many as 16 interceptors (GBI) at Fort Greeley, Alaska and 4 interceptors at Vandenberg AFB, California; However, no mention is made regarding the number of interceptors at the KLC. *Why not?* Are missile silos being proposed for Kodiak Island? If so, how many? If not, state the launch method. The safety hazards of launching interceptors from the KLC should have been discussed in the Draft PEIS, considering the high winds which occur on Kodiak Island throughout the year-- peak gusts up to 35 miles per hour in June and 83 miles per hour in December (PEIS Volume 2, Page H-18, Section H.2.1—Air Quality). As Kodiak residents have previously pointed out to the MDA in other EA comments (which the MDA has ignored), launching missile targets, and now possibly *interceptors* in a southwest trajectory down the East side of Kodiak Island would be extremely risky and potentially hazardous should a launch accident occur, because of populated native villages (e.g. Old Harbor and Akhiok) which are within the 'explosive safety hazard zone'.

Include in the PEIS the projected *cumulative impacts* from 'radiation fallout' for all space-based weapon systems (lasers, interceptors, warheads, e.g.).

Page 4-112, Section 4.1.4--Cumulative Impacts, does not give any useful or detailed information regarding the 515 projected BMDS launches during 2004-2014. The PEIS needs to include a breakdown of the 515 proposed launches and where each launch will take place (ground-based, sea-based, and space-based test locations). Where did the MDA come up with the 'magic' number of 515? A total of only 10 launches per year have been proposed from the KLC in previous EA documents (Air Force, Army). The MDA needs to validate and justify the need for 515 launches, considering the fact that 'Emissions from activities for the proposed BMDS include carbon monoxide, sulfur oxides, nitrogen oxides, volatile organic compounds, hazardous air pollutants, and particulate matter'. 'Most sites where activities for the proposed BMDS may occur would be classified as a major emissions source' (BMDS Draft PEIS Volume 2, pages H-18- H-19—Existing Emission Sources)

The Arctic Council comprising government representatives from Canada, Denmark, Finland, Iceland, Norway, Russia, Sweden and the United States, recently completed a report (October 21, 2004, Cambridge University Press), 'Impacts of a Warming Arctic: Arctic Climate Impact Assessment' (ACIA), which stated the Arctic is warming at an alarming rate. Scientists have not determined how much of the warming is due to human influence and how much is due to natural climate cycles, but whatever the cause, it is currently affecting indigenous Arctic people (hunters falling through the melting ice, declining reindeer herds and difficulty traveling in road less regions with no snow for sleds). U.S. Senators John McCain and Joe Lieberman said: "dire consequences of global warming in the Arctic underscores the need for their proposal to require U.S. cuts in emissions of carbon dioxide and other heat-trapping greenhouse gases (Associated Press, November 9, 2004).

The MDA's own admission in the Draft PEIS confirms the fact that: "Launches can contribute to cumulative impacts including ozone completion, global warming, and orbital debris, which could affect global warming and depletion of the stratospheric ozone layer (Volume 2, page I-2—Cumulative Impacts).

DC_E0319

The MDA must discontinue all future BMDS test plans which will contribute to further global warming or contamination in the affected Biomes listed in the PEIS; especially the Arctic Tundra Biome and the Sub-Arctic Taiga Biome-which includes areas of the Aleutian Chain where various radars or sensors are activated or will be activated as part of the proposed BMDS (e.g. Adak Island where the Sea-Based X-Band Radar will be home-ported, Shemya Island where the COBRA DANE is located, and the BOA in the Gulf of Alaska).

The 1990 Clean Air Act Amendments identified 188 chemical pollutants which cause or contribute to cancer, birth defects, genetic damage, and other adverse health effects. "The PEIS has not identified any environmental health and safety risks that may disproportionately affect children, in compliance with Executive Order (EO) 13045 as amended by EO 13229" (PEIS page 4-134, Section 4.7).
Executive Order 13045 of April 1997, states that each Federal agency, including the Department of Defense (as defined in 5 U.S.C.102)

(a) shall make it a high priority to identify and assess environmental health risks and safety risks that may disproportionately affect children, and
(b) shall ensure that its policies, programs, activities, and standards address disproportionate risks to children that result from environmental health risks or safety risks.

Executive Order 13229 (October 9, 2001) does not change the requirements of EO 13045 (April 21, 1997), it only amends section 3-306 of that order "for a period of 4 years from the first meeting" and inserting in lieu thereof "for 6 years from the date of this order". The PEIS cannot identify environmental health and safety risks if the Department of Defense (MDA) has not requested any studies on the issue.

The PEIS should include any environmental health hazard studies the Department of Defense(DOD) has done since 1997 on children living in communities near rocket/missile launch sites and/or U.S. military training bases world-wide. An excerpt from an October 1, 2004 DOD news release titled: 'DOD, California Perchlorate Sampling Prioritization Protocol Reached', stated: "Currently, no drinking water standard for perchlorate has been adopted". According to the news article, the DOD apparently is finally agreeing to involve itself with environmental studies, along with the state of California, to research the findings of large quantities of perchlorates in the state's drinking water. Since perchlorate is a rocket and missile propellant, and there have been no previous drinking water standards for the chemical, the PEIS cannot state without conclusive studies that there has been no health and safety risks to children (or the general public) who live near test launch sites.

Executive Order 13045, Section 1. Policy 1-101 states: "A growing body of scientific knowledge demonstrates that children may suffer disproportionately from environmental health risks and safety risks. These risks arise because: children's neurological, immunological, digestive, and other bodily systems are still developing; children eat more food, drink more fluids, and breathe more air in proportion to their body weight than adults". Section 2-203, "Environmental health risks and safety risks means risks to health or safety that are attributable to products or substances that the child is likely to come into contact with or ingest (such as the air we breathe, the food we eat, the water we drink or use for recreation, the soil we live on, and the products we use or are exposed to)". Once again, refer to Draft PEIS Volume 2, pages H-18, H-19—Existing Emission Sources; "Most sites where activities for the proposed BMDS may occur would be classified as a major emissions source". It is the *major emission sources* related to MDA activities, which has the people living near launch test sites concerned. The PEIS should include *ALL* test sites locations that will be affected by future BMDS activity.

Another area of concern that is mentioned in the Draft PEIS, is the MDA's current testing of Israel's 'Arrow Weapon System' in the United States. The October 24, 2003 'Arrow System Improvement Program (ASIP) Environmental Assessment' (EA), discusses the MDA testing of the system over a 4 year period, with "targets being launched from either the Mobile Launch Platform in the Point Mugu Sea Range or Vandenberg AFB". According to the Arrow System EA, the Arrow interceptor would intercept a "liquid-fueled target system (LFTS) that uses a main liquid fuel, an oxidizer, and an initiator fuel for vehicle motor ignition and propulsion". The EA further states: "the Arrow interceptor missile is a two-stage vehicle launched from a six-pack mobile launcher. The missile contains approximately 1,670 kilograms (3,600 pounds) of solid rocket propellant in the booster. The interceptor with the propellant has a hazard classification of 1.3 and consists of hydroxyl terminated polybutadiene (HTPB), ammonium perchlorate, and aluminum powder. The interceptor also contains an optical (infrared) seeker and a radar sensor. The payload includes a focused blast-fragmentation warhead, with a hazard classification of 1.1D. Combined, the Arrow interceptor missile with its payload has a hazard classification of 1.1."

Considering the Arrow interceptor missile has a Hazard class of 1.3 ('mass fire') and the payload's warhead a Hazard class of 1.1 ('mass explosion'), the PEIS should include information on all potential ground-based hazards (and locations) and space-based hazards from the Arrow 'interceptor' and exploding 'warhead' that will release

DC_E0319

chemicals and add to further air and land contamination if there is a launch accident (or even if there is not an accident). Also, list the name of the warhead in the PEIS. It should have been listed in the Draft.

In fiscal year 2004, the ASIP "Caravan 2 would consist of two flight tests of the enhanced Arrow Weapon System at a U.S. test range (to be determined) against a threat-representative target at approximately full range" (BMDS Draft PEIS, Volume 2, page D-46).

The October 24, 2003 'Arrow Weapon System Improvement Program EA'—Alternatives to the Proposed Action—Alternatives Not Carried Forward, states: "A number of candidate test ranges were examined, in addition to the Point Mugu Sea Range. All of the candidate test ranges were analyzed for various operational and technical considerations including safety, range availability, instrumentation, operational cost, and logistical support. At the conclusion of the evaluation, only the Point Mugu Sea Range met the ASIP test program requirements".
This is contradictory with the statement in the Draft PEIS (Volume 2, page D-46), which states a U.S. test range "'would be determined" for the Caravan 2 flight tests.

Since the release of the ASIP EA in 2003, the BMDS PEIS should include all updated plans to launch the Arrow interceptor missile from other test launch sites/locations (e.g. Reagan Test Site, Kwajalein Atoll, Aleutian Chain, Gulf of Alaska, Poker Flats Rocket Range, Fort Greeley, or the Kodiak Launch Complex).

The fact that Israel does not have land available for 'interceptor' missile testing, does not justify the MDA's decision to bring and test another country's 'experimental' war weapons into the U.S, which will contribute to the pollution of U.S. oceans, drinking waters, air and land. Nor should the MDA be helping Israel by testing weapons that will then be shipped back to Israel to be used against its enemies in its 'religious' war, in order to further the 'Israeli Terminal Missile Defense' program. The United States should be doing what it can to negotiate peace rather than promoting war via another country.

The wording is not much different in the excuse the MDA gives for testing the Arrow interceptor in U.S. territory-"Commitments to Israel would not be fulfilled, and the United States would not realize any benefits to its own Terminal Missile Defense test program from participation in the ASIP" (Arrow System Improvement Program EA, October 24, 2004). Regarding the BMDS Draft PEIS and No Action Alternative, the MDA comments: "This alternative would not meet the purpose of or need for the proposed action or the specific direction of the President and the U.S. Congress to defend the U.S. against ballistic missile attack". Perhaps the PEIS could explain exactly what the President and Congress have proposed for the BMDS, because the MDA evidently does not know 'the specifics of the final architecture or operational requirements' otherwise, the information would have been included in the Draft PEIS, so the public would have an Alternative 3 option to comment on that did not include 'exploding' missiles in space or firing space-based lasers at ground targets, which eventually will lead to the U.S. Department of Defense's control of space by the year 2020 (U.S. Air Force, Vision 2020).

The PEIS needs to explain how the method of launching and exploding missile targets and interceptors in space is going to protect the U.S. borders and coastlines and deter 'terrorists' threats or attacks. Unless the MDA plans on tracking terrorists by infrared satellites, firing an Israeli 'Arrow' interceptor or space-based laser weapon at them before they cross over U.S. borders, the BMDS will prove to be useless in protecting the United States.

Since no Alternative 3 is listed, the BMDS Draft PEIS is also 'useless' and a waste of the public's time to comment, because the MDA really does not care to hear what the public has to say, and most likely, Volume 1 of the BMDS PEIS has already been printed and the MDA is waiting to receive and include public comments before releasing it and publicly announcing to the news media that the BMDS is 'deployed'.

Please send an e-mail acknowledgement that my comments have been received. Thank you.

Subject: Comments on the BMDS PEIS

To Whom It May Concern,

I've been alerted to the problems of BMDS and am submitting these comments on the PEIS.

My major concerns have no place in the narrow confines of the comment process but I add them at the end anyway because the unintended consequences of many seemingly benign endeavors have come back to haunt humanity.

To directly address the impacts of BMDS, I have these comments:

1. It is too expensive for what we get. The opportunity cost of that money going to BMDS could bankrupt us the way the USSR exhausted itself with its military budget. We would be better off with a more educated population who have decent jobs, and a cleaner environment, which we won't be able to afford.

2. The hydrogen chloride injected into the atmosphere with each launch has incredible potential to neutralize ozone, enlarging the famous hole which now requires Australian school children to be outside only with hats and long-sleeved shirts.

For the larger picture:

As a teenager, I was proud that my father worked for the Arms Control & Disarmament Agency. Besides the huge tax savings that resulted from the test ban treaties, we have no idea of what sort of nuclear catastrophe we avoided.

Much later, when President Reagan brought up his Star Wars notion, the feasibility reports made it clear what a ridiculous idea this was, like trying to stop a bullet with a bullet. Nevertheless, by preying on Americans' fears, Star Wars was moving ahead. Luckily, the collapse of the Soviet Union ended the foolishness.

By building Star Wars, we set a terrible example to other nations that we intend to be invulnerable, and therefore we become a threat to all other nations. They have no reason to trust us not to initiate war.

We now live in a world of terrorist threat. We need to learn that resentment of imperious America fuels more violence than we can ever head off, and that threats to our security will be as low tech as having religious fundamentalists give up their lives to pilot planes into office buildings. Fairness, respect, and cooperation are key in defusing

True, there are other nuclear nations that could launch against us. However, it would be far wiser to give every North Korean, Pakistani and Indian a share of what it would cost to build Star Wars so they can buy land, build houses, start businesses, and educate their children. Peace comes from contented people in prosperous nations.

Americans don't pay much attention to complex technological and scientific issues. But when they find out the monetary and social costs of following the wrong experts' advice, they get very angry.

Citizens rose up to stop above ground atomic bomb testing and supported the test ban treaty. We insisted on the Clean Air and Clean Water Acts. We buy more organic food every year because that is safer to eat and better for the environment.

Why not do the right thing now, instead of trying to clean up the mess later? An ounce of prevention is worth a pound of cure.

Subject: BMDS PEIS

Peter G. Cohen

November 15 2004

BMDS PEIS

PURPOSE: As all of the nations capable of deploying intercontinental ballistic missiles are either allies or friendly, the need for this system has not been established.
The real danger of hostile nuclear weapons being delivered to the United States or allies by rogue nations is not addressed by this program. The real danger being the sale or theft of nuclear materials by hostile nations or groups from existing stocks. It is well known that these stocks are not properly guarded or disposed of and that insufficient moneys are being deployed by the U.S. to accomplish this defensive measure promptly and completely.
Thus, the real danger is not addressed by the proposed action, while its extreme technical difficulties and great cost further delay the prompt securing of radioactive materials worldwide.
Furthermore, this Maginot Line in the sky will stimulate other nations to develop the means to penetrate this defense before it is even completed. For example, our own new high speed drone could deliver a weapon at such speed as to make interception impossible.

PROPOSED ACTION: The definition of the proposed action includes preparations and deployment, but does not mention use of the proposed integrated system. If it is deployed and used against missiles carrying nuclear weapons, the detonation of these weapons in flight will cause radioactive materials to be widely dispersed in the atmosphere around the world. Recent studies by the CDC /NCI conclude that thousands of Americans have contracted cancers and died from U.S. testing of nuclear weapons 1950-61. Recent studies in the Chernobyl area have shown that genetic defects caused by radiation are passed down from generation to generation. In other words, there is a very real danger that the use of this system would further degrade the human gene pool. The effects upon the continuation of ocean life are unknown.
The testing of the system at Vandenberg AFB has inevitably had the effect of polluting the surrounding area with perchlorates. We do not know the extent of birth defects and growth retardation caused by rocket fuel in this area because no studies among this population have been done. The testing and deployment of the BMDS should be halted until the effects on the human population are known.

METHODOLOGY: Most scientists agree that the process of ³incrementally develop and deploy² being used in this system is the most expensive and least feasible method of developing a working system. As you are well aware, many of the necessary systems have not been tested and no tests have come close to battlefield conditions. It is against Pentagon rules for procurement to go forward on an unproved system.

CONCLUSION: As the environmental impacts of testing and operating this system are dangerous to an unknown degree, and as the benefits to be derived are highly questionable and alternative protections in universal nuclear disarmament are both pledged by the U.S. and possible, no further funds should be

DC_E0326

appropriated and testing and deployment should cease immediately.

Subject: Star Wars PIES

1. The three alternatives being considered are insufficient and deceptive. "No Action" is an endorsement of the current ABM program which is badly flawed and which should be terminated. The PIES as it is being conducted does not meet congressional requirements and must be started over with real alternatives.

2. Placing weapons in space is inherently destabilizing -- upsetting international relationships, forcing response in kind, creating dangerous confrontations, accidents, and errors. If weapons are placed in space they will be used in space resulting in disasterous pollution by debris, and most probably, by radiation.

3. We already know from previous tests that nuclear weapon detonations in or near space cause long-term radiation pollution and serious disturbance of the Van Allen belts, damage and destruction of satellites over vast expanses of space, as well as interruption of power grids and communication nets on the ground. Once weaponization of space starts the use of nuclear weapons will be unavoidable, and of terrible consequence to the US.

4. There is no such thing as a purely "defensive" weapon. Once a weapon is created and deployed it can, and will, be used offensively. The Star Wars objective, "To project the power of the US globally so as to dominate the world" (a quote from the AFMSC presentation) is that of apocalyptic visionaries and has no place in rational considerations of US best interests. The Star Wars concept does not advance or protect the interests of the US, it destroys and defeats our true and traditional interests. It is not a defensive system, it is offensive in every meaning of the word.

5.. I have spent a lifetime working with missles and satelites. I know just how reliable they and the people who operate them are. I find it easy to foresee the disasters that will occur with a new collection of weapons on earth or in orbit designed for instant activation, instantanious response. We shot down an innocent commercial airplane over the Mediterranean using "conventional" weapons. Just think of the accidents we will cause with Star Wars !!

6. There is no actual threat to the US that can possibly justify Star Wars. There is no conceivable threat that Star Wars weapons could address that could not be met more effectively by other means already available. There is no reason for Star Wars -- just the irrational ambition of some to dominate the world. And the cost!!! We have already poured 100 billion dollars down the ABM rathole -- and into the aerospace industry for a useless, untested "system" that won't work, deployed against no threat. We must not continue this enormous waste while our infrastructure, our schools, our health programs suffer for lack of funds. We are a nation of idiots!

Missile Defense Agency
MDA BMDS PEIS, c/o ICF Consulting
9300 Lee Highway
Fairfax, VA 22031

Missile Defense Agency:

I am writing to support a real "No Action" alternative to the deployment of a missile defense system. This means no further testing, development, or deployment. Deployment of such a system threatens a new nuclear arms race, puts the global environment at risk, and does not improve the security of the United States.

Sincerely,

anne kelly

WOMEMWITH HILL WOMEN'S PEACE CAMP(AIGN)
C/o 8 Somerville Terrace, East Busk Lane, Otley, West Yorkshire, UK

Submission for the attention of

MISSILE DEFENSE AGENCY
DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT
Mda.peis@cfconsulting.com

[Further details and supporting evidence for all statements made in this submission are available on application to Anne Lee, only if required for the purposes of the public consultation relating to US Missile Defense Agency's Programmatic Environmental Impact Statement]

Introduction

WoMenwith Hill Women's Peace Camp(aign) is a non-violent direct action campaign focused in opposition to Menwith Hill Station and in addition calling for the closure of US Bases in Britain and around the world. We are also affiliated to the Global Network Against Weapons and Nuclear Power in Space, the Yorkshire Campaign for Nuclear Disarmament and the Menwith Hill Forum (a locally-based group set up to examine issues of public concern resulting from the presence of the US Bases at Menwith Hill and Fylingdales).

The WoMenwith Hill Women's Peace Campaign is aware of, and supports all objections to, the degradation of the earth and space environments, which are and would result from implementation of the United States' Missile Defence programme. It is with this overall detrimental impact in mind that we submit our representation, specific to the programme's environmental impact at the ground stations and more specifically at Royal Air Force Menwith Hill and Royal Air Force Fylingdales Stations in the British Isles.

Crucial to the US Missile Defence programme is the stationing of 'forward surveillance' facilities located outside the continental USA at US Bases on land it is permitted to use by host nations. The political structure of such nations may be very different from the Federal Government (e.g. Britain is a Monarchy: q.v. 'Crown Defence Land'). The legislation regulating environmental controls in other countries may be very different, possibly more stringent, than that which obtains within the USA. It is incumbent on the Missile Defense Agency to apprise itself of, and publish an undertaking to comply with, mandatory statutory requirements wherever on the Earth it proposes to site Missile Defence facilities.

We submit that the following observations, although relating mainly to our personal experiences of the position at the US Bases at RAF Menwith Hill and RAF Fylingdales, both in North Yorkshire, England, have wider relevance. The Missile Defense Agency's Programmatic Environmental Impact Statement must acknowledge and include Environmental Impact Assessments for each and every US Missile Defence Base proposed to be sited on land in nations with British or British Commonwealth status, and also in other independent sovereign nations (e.g. Denmark's sovereignty over Thule).

The global ground stations operate as:

- Downlink and relay stations for a global surveillance network, principally deploying signals' intelligence and photo-reconnaissance satellites to assess *inter alia* preparations to launch intercontinental ballistic missiles (ICBMs).

- Downlink and relay stations for a satellite infrared tracking system to provide early warning of and tracking, after launch, of ICBMs targeted on the continental USA.

- Early Warning Radar Stations positioned around the Arctic Circle to identify a launch of ICBMs targeted on the continental USA and continue to track them in flight.

- Proposed launch sites for interceptor missiles to attack ICBMs.

Global Surveillance Network

The long-established US satellite-surveillance downlink and relay Bases, such as Menwith Hill and Pine Gap, positioned around the world for the purpose of intelligence gathering, are necessary components of the US Missile Defense System, as they would be used to monitor in advance, the preparations for the launch of a rocket. These facilities comprise part of the US Missile Defence system package and exclusion from the US Missile Defence Agency's Programmatic Environmental Impact Statement deliberations cannot be justified.

Britain and the British Commonwealth conveniently provide the USA with land for its surveillance stations around the world. Because of the 'special relationship' binding Britain, the USA considers that ground stations located on British or British Commonwealth soil to be particularly secure. Thus the USA has surveillance facilities located in the British Isles, Canada, Australia, New Zealand, Ascension Island and Diego Garcia or co-located with British surveillance facilities (e.g. Cyprus).

The British Government has been compliant in acceding to the wishes and interests of the USA, even going so far as to evict the population of the Chagos Islands to permit the construction of the US Base on the island of Diego Garcia.

US Missile Defence at Bases in Britain: Recent History

Specific to the US Bases in England, the British Government has already granted permission for the USA to upgrade the Early Warning Radar at Fylingdales and agreed that, if necessary it may be used for US Missile Defense. Further formal requests for the Missile Defense use of Menwith Hill, as a satellite downlink and relay for infrared tracking systems; construction of an X-Band Radar, and the stationing of the interceptor missiles in Britain, are anticipated.

RAF Fylingdales

The formal request for the use of RAF Fylingdales for US Missile Defence purposes was announced by the Rt Hon Geoff Hoon, Secretary of State for Defence, in the House of Commons on 15 December 2002. His decision to grant permission was deferred to allow a public consultation exercise to be carried out. This was curtailed by the imposition of a deadline of 15 January 2003 (the Christmas Recess of Parliament intervened) for representations to be submitted to the House of Commons Defence Committee and 31 January 2003 for the public announcement of his decision.

In January 2003, we contributed submissions to the deliberations of the House of Commons Defence Committee. The public consultation period was a totally inadequate farce of democratic procedure. The Committee was extremely worried that the Secretary of State for Defence had rushed through the procedure with unseemly haste and even publicly announced his decision prior to issuance of the Committee's conclusions.

On 29 January 2003, the House of Commons Defence Committee published its conclusions. (*MISSILE DEFENCE Report of Session 2002 – 03, HC 290 – 1*). It contained a strongly worded criticism accusing the Secretary of State for Defence of stifling the debate:

'Despite the Secretary of State's unequivocal statement that he wanted the decision to be informed by public and parliamentary discussion, he has acted in a way that has effectively curtailed such discussions…

'…we deplore the manner in which the public debate on the issue of the upgrade has been handled by the Ministry of Defence. It has shown no respect for either the views of those affected locally by the decision or for the arguments of those opposed to the upgrade in principle.'

The Committee demanded further information about the nature of the Early Warning Radar upgrade, its operations and the impact on the environment. They stated that:

- The upgrade will not simply be replacement of old computer systems. It will be a change of use.
- In addition to the radar identification and tracking capabilities the upgrade will incorporate *'support* [for] *the capability of the interceptor missiles'*.
- The existing agreements, which allow the USA's operations at Fylingdales and Menwith Hill, do not permit the use of these Bases for US Missile Defence.
- The possible hazard of the radio frequency radiation emissions from the radar had not been properly investigated and there was considerable public concern.

Nevertheless the House of Commons Defence Committee did conclude that it was permissible to allow this limited upgrade Fylingdales Early Warning Radar and its use '*in missile defence mode*' for US Missile Defense purposes.

Their conclusion is wrong.

The installation and operation of components of the USA's Missile Defense System on Britain's Crown Defence Land is unlawful and would require a new Act of Parliament.

The Defence Committee's demand for further information was acknowledged on 16 June 2003 by the UK Ministry of Defence's publication of a Report: *'Upgrade to RAF Fylingdales Early Warning Radar – Environment and Land Use Report'*. This may be found at http://www.mod.uk/publications/raf_fylingdales_upgrade/

The MoD's Report did not address the Committee's concerns

- About the implications of the change of use.
- Whether the existing agreements legally permit the development.
- It dealt inadequately with the concerns about the effects of the radar emissions.

The MoD's Report is also inaccurate in several identifiable areas.

The MoD's Report is not an impartial assessment conducted by an independent inspector. Its purpose is a propaganda exercise, to reassure Parliament, the public and especially the North York Moors National Park Authority, the local Council responsible for the upkeep of the National Park, which includes the Fylingdales area. The MoD's Report asserts that no Planning Application for the radar upgrade would be necessary, because the environmental impact would be *de minimus.*

A Planning Application, which would necessitate consultation with the Council's Planning Committee, would have allowed the public the opportunity to make comments and objections at a public Council Meeting reported by the media. Objectors to the development were thus denied the opportunity of a platform to state their arguments and make demands for an impartial Environmental Impact Assessment, Archaeological Survey and Public Inquiry.

A '*Response*', to the MoD's Report, submitted on behalf of WoMenwith Hill Women's Peace Camp(aign), was delivered to the North York Moors National Park Authority, in advance of its full Council Meeting on 29 September 2003. At this meeting the decision relating to the requirement for a Planning Application for the Fylingdales' upgrade was to be determined.

Six days in advance of the supposed democratic, decision-making meeting, the media published a statement from the Council that no Planning Application was required. The Chief Planning Officer's decision, was based on the assurance in the MoD's Report that, because there would be no alteration to the physical appearance of the site and no increase in Radio Frequency power radiating from the pyramid, there could be no grounds requiring submission of a Planning Application.

'Change of use' of premises (e.g. a shop to offices) normally requires a Planning Application and would have justified such for the Fylingdales upgrade.

The WoMenwith '*Response*' was circulated to the UK Ministry of Defence Estates' Organisation in September 2003. To date no reply has been received. We believe this may be because the Ministry of Defence is avoiding addressing the assertion that their Fylingdales' Upgrade Report contains inaccuracies.

The Defence Secretary's decision, in December 2002, to defer consideration of the associated X-Band Radar (which would be a major construction and would require a Planning Application and probably Public Inquiry) may be a reaction to the strength of public opinion. In 2002, the media reported widespread public concern about the abrogation of the Anti-Ballistic Missile Treaty; the implications of Britain's involvement with 'Star Wars' and fears that the upgrade of Fylingdales represented the 'thin end of the wedge'. Many people suspect that by deferring consideration of X-band Radar plans to a future date, the Secretary of State for Defence was deploying a tactic to try to defuse objections by introducing the US Missile Defence programme's components in piecemeal instalments.

Although the Fylingdales' radar upgrade was stated not to justify a Planning Application, this would not be true of either X-Band Radar installations or missile interceptor launch sites. Proposals to construct such would generate mass opposition. There would be objections from the peace movement and environmentalists internationally in addition to local concern for the consequential environmental degradation to the locality. US Missile Defence developments would be challenged through Parliament and the normal channels for presentation of arguments at Public Inquiries.

Some of the opposition to further developments would involve an escalation of non-violent direct action, similar to that at Greenham Common in the 1980's.

On 13 April 2004, BBC TV carried the news that work had started on the Fylingdales 'revamp'.

On 17 October 2004, the media carried the 'leak' that a secret, top-level agreement had been reached to permit siting of missile interceptors in Britain.

On 14 November, *The Observer* published a letter from the Secretary of State for Defence denying that missile interceptors would be placed at Fylingdales or that any secret discussions had taken place.

Menwith Hill

It is not generally acknowledged that the whole of Menwith Hill's Operations plays a role in US Missile Defense.

The long-established signals' intelligence systems have the capability to detect the advance preparations prior to a missile launch, and convey that information via the US National Security Agency's Defense Special Missile and Aeronautics Center at Fort Meade.

Two radomes and operations buildings for a space-based infrared tracking system have already been installed and the Station's organisation restructured, in advance of any permission for its use for US Missile Defense. The satellite infrared capability can track ICBMs at and after launch.

During the past two years or more there has been a steady stream of Planning Applications to the Harrogate Borough Council for infrastructure expansion at Menwith Hill. Indications are that the Base operations are due to expand c. 50% (e.g. a recent Planning Application is for 50% increase in the electricity generated for use by the satellite downlink and computer operations).

As at Fylingdales, there are suspicions that dribbling through the Planning Applications may well be a deliberate policy to defuse objections. Gradual introduction of these plans means that each is considered individually and not in the overall context of the as the total package. Public opposition, therefore, has been virtually non-existent

Because of regulations relating to developments on Crown Land (q.v. 'Crown Defence Land: Ownership, Occupation and Use') prior to the introduction of new legislation in May, the Harrogate Borough Council had no statutory powers of enforcement should it have objected to any of these proposals for expansion at Menwith Hill. In practice the law has never been tested, because the Council almost unanimously supports the presence of the US Base. It is one of the biggest employers in the district and is said to benefit the local economy by $62M annually. A statutory Public Inquiry, which would provide a well-publicised platform for objections to be heard, can happen only by the Council's application. It may thus appear to be unrealistic in the prevailing circumstances to expect that the Harrogate Borough Council would ever request it.

There have however been two recent changes in legislation governing developments considered to have significant environmental impact. These are the provisions of the Aarhus Convention, allowing the public to have greater participation in decisions impacting on the environment and the European Parliament's removal of the Crown Land exemption from the Environmental Impact Assessment, which must accompany any substantial development proposals (q.v. 'Crown Defence Land: Developments: Environmental Impact').

An argued case calling for Environmental Impact Assessment, Archaeological Survey and a Public Inquiry was submitted by WoMenwith Hill Women's Peace Camp(aign) to the Harrogate Borough Council's Planning Department, and the Ministry of Defence Estates' Organisation, in response to a recent Planning Application to enclose the whole of Menwith Hill, including the areas of pasture, inside a razor-wire topped security fence bristling with CCTV cameras.

The case was submitted in January 2004, prior to the changes in the relevant legislation in May.

On 26 February, under the 'delegated legislation' arrangements, a non-elected Civil Servant (a Planning Officer) approved the plans.

Neither these plans, nor any others in the past two years, have been put on the Agenda for deliberation by the elected members of the Council's Planning Committee Meeting.

Crown Defence Land: Ownership, Occupation and Use: the Law

Ownership of Crown Land

Defence Land is designated 'Crown Land'. The three categories of Crown Land are:

- 'Crown Estate' is land owned by the monarch, the revenue from which accrues to the State in exchange for an income, apportioned by Parliament, for the royal family (the Civil List).
- Duchy of Lancaster and Duchy of Cornwall Lands are in the private possession of the monarch and the heir to the throne.
- Land owned by the State and administered by Her Majesty's Government, such as the Ministry of Defence. During the term of his Office, the Secretary of State for Defence is deemed for legal purposes to be the owner of the Crown Defence Lands, held in his trust on behalf of the nation.

The size of the Crown Defence Estate in the UK is 240,000 hectares (593, 052 acres). This includes considerable areas in North Yorkshire, England, most of which was appropriated during World War 11 and is surplus to any current requirement for military purposes.

Menwith Hill Station and Fylingdales Station are both located on Crown Defence Land in North Yorkshire.

Acquisition and Use of Land by the Secretary of State for Defence: the Law

The appropriation and management of land for the purposes of the defence interests of the British Isles is regulated by the Defence Act 1842 and the Military Lands Acts 1892 to 1903 plus subsequent amendments (e.g. to incorporate the Royal Air Force).

Defence Act 1842

Title: '*Acquisition and Use of Land'*

'Citation: to consolidate and amend the Laws relating to the Services of the Ordnance Department, and the vesting and Purchase of Lands and Hereditaments for those Services, and for the Defence and Security of the Realm'.

The 1842 Act, therefore, states specifically the purpose for which land in Britain may be appropriated and its use for '*the defence and Security of the Realm*'.

The Defence Act 1842 is the legislation passed by Queen Victoria, which established 'Her Majesty's Surveyors of Ordnance'. The Ordnance Survey, instituted for military purposes, eventually became the UK statutory civilian authority for mapmaking. Unless Parliament were to pass new legislation re-establishing Her Majesty's Ordnance Survey Department, the 1842 Act cannot be repealed.

The 1842 Act empowers the Secretary of State for War (now Defence) to purchase land either by agreement with the landowner or by compulsory purchase. The Act permits surveyors to enter onto privately owned land in order to survey it for the possibility of acquiring it for military purposes.

The Military Lands Act 1892

'PART 1

Powers to purchase land. – (1) A Secretary of State may purchase land in the United Kingdom under this Act, for the military purposes of any portion of Her Majesty's military forces'.

The 1892 Act is an attempt to form a single body of legislation incorporating and/or repealing the previous different Acts passed throughout Queen Victoria's reign.

The 1892 Act defines the extent of, but also the limitations on, the Secretary of State's management of Crown Defence Lands: *'…for the military purposes of any portion of Her Majesty's military forces'.*

Occupation of Crown Defence Land by a Foreign Power: the Law

The occupation of Crown Defence Lands by the visiting forces of a foreign sovereign power is governed by the provisions of the North Atlantic Treaty Organisation's Status of Forces Agreement (NATO SOFA), which was signed in London on 19 June 1951, later ratified by the UK Parliament as the Visiting Forces Act, 1952.

Article 1X (s.3) of the Visiting Forces Act states:

'…the authorities of the receiving State shall assume sole responsibility for making suitable arrangements to make available to a force or civilian component the buildings and grounds which it requires…'

The 1951 NATO SOFA was agreed

'…appropriate to the relationship which exists between the United Kingdom and the United States for the purpose of our common defence' (Jeremy Hanley, Minister of State for the Armed Forces, in reply to the late Bob Cryer MP, 25 March 1994. *Hansard*)

The stipulation '*arrangements for common defence'* is stated by the NATO SOFA, the Visiting Forces Act and repeated in the updated International Headquarters and Defence Organisations Act 1964.

In 1999 the legislation was amended by Order in Council to take account of recent changes in legislation (e.g. the Town and Country Planning Act 1990). The amendment to the existing legislation is the Visiting Forces and International Headquarters (Application of Law) Order 1999 (Statutory Instrument 1736).

Significantly, in light of the USA's request for its unilateral use of lands allocated for NATO purposes, the 1999 Statutory Instrument omits to repeat '*arrangements for common defence'*. Nevertheless, as the originating Acts have not been repealed, the condition stating *'arrangements for common defence'* remains applicable.

The Law is specific, the Secretary of State is granted statutory powers to acquire and manage land for the purpose of the defence of the realm - and not for the purpose of the exclusive defence of a foreign power, whatever the relationship between Britain and that nation.

The Law does not empower the Secretary of State to grant the USA, or any other foreign power, military use of the Crown Defence Lands in his care, unless it is specifically used for the defence of the British Isles. Thus the Law would disallow the USA's use of UK Defence Lands for the USA's Missile Defence system, which is not designed to protect the British Isles from an attack by Intercontinental Ballistic Missiles. US Missile Defence is exclusively for the protection of the continental USA.

The Law allows foreign power member of NATO to conduct military activities on Crown Defence Land in support of NATO. For example, to comply with the Law, the interception of communications by the US National Security Agency at Menwith Hill Station must be for military purposes only - and on behalf of NATO. The collection of intelligence exclusively for US national interests or any other purpose (e.g. political, diplomatic or commercial, such as the collection and distribution by the ECHELON global network) is an illegal misuse of Crown Defence Land.

This begs the question of whether the NATO SOFA '*arrangement*' for the USA's occupation and use of Menwith Hill and Fylingdales is legitimate and whether the Secretary of State for Defence knowingly colludes with the conduct of illegal activities (q.v. 'Collusion: Environmental Impact'). The Law is clear - the entire function, not just part, of the operations at Menwith Hill Station and Fylingdales must be for British and NATO military activities conducted in defence of the UK.

The High Court of the Royal Courts of Justice has examined in what circumstances the US Bases' authorities are exempt from compliance with the law and the jurisdiction of the Courts (Menwith Hill US Base Commander, Colonel G Dickson Gribble v Helen John, 31 July 1997).

The Office of Secretary of State, whether of Defence or of any other UK Government Ministry, does not confer on its holder a statutory authority to negotiate disposal of national assets, such as Crown Defence Land, to a foreign power.

It would appear that the Secretary of State for Defence, the Rt Hon Geoff Hoon MP, has exceeded and abused the powers granted to his office.

We believe his action is in Law *ultra vires* and *mala fides* and therefore Treason.

Crown Defence Lands: Developments: Environmental Impact

Since the Fylingdales and Menwith Hill submissions, there has been a significant step towards implementation of the Aarhus Convention, which gives the public greater participation in the decision-making process related to developments having impact on the environment.

In January 2004, the European Commission considered taking legal action against the UK over failure to comply with European Union's legislation requiring that Environmental Impact Assessments be carried out prior to certain developments. The European Commission took the first step in the legal procedure, when it issued a final warning to the UK Government, stating that its legislation was inadequate to cover developments on land owned by the State (i.e. Crown Land).

Crown Land was excluded from statutory planning enforcement and exempt from the various UK regulations transposing the EU's Environmental Impact Assessment Directive (85/337/EEC as amended by 97/11/EC) into UK Law.

The UK Government maintained that administrative procedures already existed under the Town and Country Planning Act 1984 (Department of the Environment Circular 18/84) to ensure public consultation on Crown Land developments. However, the European Commission considered that legislative measures incorporating statutory powers were needed. The UK Government accepted this as necessary and the relevant legislation removing 'Crown Immunity', the Planning and Compulsory Purchase Act, received Royal Assent on 22 May 2004.

Possibly it is significant that the raft of measures for the expansion of Menwith Hill's infrastructure was submitted in the two years prior to 22 May 2004.

Proposed developments on Crown Land are subject now to the normal statutory planning controls. This will include a statutory requirement to conduct Public Inquiry to consider evidence of the implications of major development proposals and to conduct a full Environmental Impact Assessment and Archaeological Survey.

It remains to be seen whether the UK Ministry of Defence will successfully argue that future developments relate to UK 'national security' and whether they can be exempted from Environmental Impact Assessment under the new legislation. Presumably the Secretary of State for Defence would have to justify such a position and produce evidence for exemption – and prove that US Missile Defense functions for the 'national security' of the British Isles.

The proposal to construct X-Band Radar or locate missile interceptors at launch sites in the British Isles would be classified as a development requiring statutory Public Inquiry conducted by an impartial Planning Inspector. This would be conducted similar to a Court of Law to hear evidence from all interested parties including members of the public. The UK Ministry of Defence would not be permitted to issue its own Environment Report, such as that for the Fylingdales' Upgrade, arguing a one-sided case, to which the public made no contribution.

The conduct of non-statutory Public Inquiry, under the previous Circular 18/84 procedure, was carried out to examine the environmental impact consequent on the Ministry of Defence's plans for developments at the Otterburn Ranges on Crown Defence Land in the Northumberland National Park. The Public Inquiries ran for five years. In October 2001, in consequence of 9/11,the Planning Inspectors' recommendations were overridden. The UK Secretary of State for Defence ordered the developments to proceed. He then had the power to do this if it was perceived to be in the interests of the defence of the realm.

The recent changes in legislation under the Planning and Compulsory Purchase Act, 2004, remain to be tested.

US Bases on Crown Defence Land: Pollution of the Environment

The former Royal Air Force Base at Greenham Common serves as an example of the contamination resulting from its occupation by the US Airforce.

The information publicly available describing the restoration and regeneration of Greenham and Crookham Commons is published on the West Berkshire District Council website **http://www.westberks.gov.uk**. The website presents only a fraction of the overall pollution picture. In practice only the surface environment has had remedial treatment. The prohibitive

cost of investigating the underground contamination means that the total detrimental impact will never be assessed.

It is not possible to assess a figure for the costs incurred in the limited restoration of the surface of the land. The West Berkshire Council's figure of c. £1.5 million does not take account of the considerable unpaid work of volunteers.

The US Government has no statutory responsibility for, and makes no contribution towards, the cost of the clean up.

Fylingdales and Menwith Hill: Environmental Concerns

The following illustrative examples comprise only some of the environmental issues about which we have made representations to the relevant authorities in recent years. This list is by no means exhaustive.

- **The Environmental Impact of Fylingdales' Solid State Phased Array Radar: Radio Frequency Emissions**

There is widespread public concern about the detrimental environmental impact created by the Fylingdales' radar pyramid.

The foremost concern is the possible harmful biological effects of the non-ionising radio frequency emissions from the radar.

For example, the local village of Goathland is a major tourist attraction because it is featured in the Heartbeat TV 'soap opera' and its antique steam railway. Goathland is in direct line-of-sight from the Fylingdales radar pyramid and is therefore a recipient of RF emissions from the 'sidelobes' of the radar.

Although the UK Ministry of Defence assures the local population that the radar is entirely safe, it sets off car alarms and disables ignition systems as far away as Goathland. The Base authorities publish a health and safety guide for employees and visitors warning of these effects and the possible danger of creating a spark by induction if attempting to fill a petrol tank using a metal container.

There is no adequate official scientific study of the biological effects on plant, animal and the human body resulting from Fylingdales' radar emissions.

Professor Dave Webb, Chair of Yorkshire Campaign for Nuclear Disarmament, has published a paper, '*Is it Safe?*' which can be read at **http://cndyorks.gn.apc.org/fdales/**. Professor Webb maintains that the safety standards are inadequate and presents the evidence to substantiate his arguments. The reassuring conclusions published in the UK Ministry of Defence's '*Upgrade to RAF Fylingdales Early Warning Radar - Environment and Land Use Report*' are based on the inadequate safety guidelines . We endorse Prof. Webb's position and submit that his paper be considered by the US Missile Defense Agency as a contribution to public responses to the Programmatic Environmental Impact Statement.

- **The Environmental Impact on the Landscape: Visual Degradation**

Both Fylingdales and Menwith Hill occupy elevated positions in rural areas of high-quality landscape – in areas economically heavily dependent on tourism. The incongruous 'sci-fi' structures, Menwith Hill's 30 giant white 'golf balls' and Fylingdales huge truncated pyramid silhouetted against the sky, are visible for miles, especially from the surrounding hills.

Fylingdales is in the North York Moors National Park.

Menwith Hill overlooks Nidderdale. The boundary of the Nidderdale Area of Outstanding Natural Beauty (eventually to be incorporated into the Yorkshire Dales National Park) was tightly drawn around Menwith Hill's perimeter to exclude the Base on grounds that it is ugly.

The National Parks are areas of the British Isles, where a strictly enforced statutory conservation policy applies to preserve the rural amenity in perpetuity as a national heritage.

Only considerations of acute emergency national security would permit developments such as Menwith Hill and Fylingdales.

- **The Impact on Britain's Archaeological Heritage**

Both Fylingdales and Menwith Hill are sites of prehistoric importance known to date from the Neolithic period or earlier. Conservation of the archaeological heritage is a prime consideration in Britain and must be considered in the deliberations for the US Missile Defense Agency's Programmatic Environmental Impact Statement. The damage to these sites so far is incalculable. Herewith two examples:

Menwith Hill:
The Base is located on Forest Moor, an area of significance to archaeologists for its Neolithic settlement, testified by the wealth of flint microliths.

The site is adjacent to an Iron-Age Brigantian Fort. The Roman Road joining the fort at Ilkley (Olicana) to the city of York (Eboracum) borders the southern boundary of the Base.

The US occupants in c.1990 removed an ancient megalith known as 'Tibby Bilton', possibly the last standing remnant of a prehistoric group or circle of standing stones.

Fylingdales (or more properly, Snod Hill):
The presence of a tumulus, a group of (fallen) megaliths and petroglyphs is evidence that Snod Hill is a prehistoric funerary site.

Snod Hill is crossed by prehistoric trackways, ancient rights of way dating from the Bronze Age or earlier, for over two thousand years in use as a 'Salt Road' from the coastal settlements. The Salt Road is notorious in later history as a route for smugglers.

The Salt Road was closed peremptorily and permanently to permit the construction of the Early Warning Radar facilities.

- **The Environmental Impact on the Land: Flora and Fauna**

The location of Fylingdales Station gives rise to concern because of its proximity to Sites of Special Scientific Interest. Special conservation measures statutorily apply to such sites. In the case of Fylingdales it is because of endangered plant species and breeding sites for rare moorland birds. No construction work is permitted at Fylingdales during the birds' breeding season – April to August inclusive.

Herewith two recent examples out of the many complaints made to the Bases' authorities:

Fylingdales:

In January 2002 the unauthorised construction of a limestone internal perimeter patrol road, part of the security upgrade in advance of its US Missile Defence role, gave rise to fears that the effect would be to raise pH levels in the surrounding acid bogs. Construction work had to be halted to allow an Environmental Impact Assessment to be conducted. This was not an impartial assessment by an independent inspector, but a mitigation exercise carried out by the UK Ministry of Defence. In the event it was concluded that to remove the road and reconstruct it in a less alkaline material would cause greater damage than to permit it to remain.

Menwith Hill:
The discovery of a colony of rare feral orchids, in natural wetland on the north-west of the Base, led to an investigation by Professor Bateman, Keeper of Botany at the Natural History Museum, the country's top orchid expert. As a result of his research in 1999, the proposed high security fence was relocated to skirt the orchid site instead of cutting through it and the Menwith Hill authorities agreed to conserve the orchids' site as a reserve. Further complaints are ongoing because of their failure to implement Prof. Bateman's management recommendations.

- **The Impact on the Water Environment**

The UK Environment Agency is the statutory body responsible for monitoring and maintaining the quality of the water environment including the public water supply. It has no access or authority to investigate the Crown Defence Land inside the Bases, but it does monitor the emergent water outflows, including the sewage and can authorise remedial action.

Herewith two examples of recent complaints:

Fylingdales:
During the heavy flooding of 31 July 2002 the Fylingdales sewage works overflowed and raw sewage ran down the hillside and entered Eller Beck at Ellerbeck Bridge east of the Base. Eller beck flows through the village of Goathland. The Goathland Parish Council was informed and discussed the issue at its August Parish Council Meeting.

Menwith Hill:
The site causes concern because of its position on the gathering ground for the city of Leeds water supply. The surface water run-off from the Base enters Swinsty Reservoir via Spinksburn Beck.

The Menwith Hill Forum made enquiries recently about the history of environmental contamination resulting from the presence of Menwith Hill. The Environment Agency responded to the request and from its enquiries it emerged that a major spill of diesel fuel (the Station generates its own electricity from diesel generators) had occurred in the mid-90's, but that all the documentary evidence had been destroyed. The only surviving evidence is the memories of those personnel who were engaged on the remedial clean-up.

The fact that there was no public announcement at the time of this incident is one example that serves to indicate that it is not possible for statutory public authorities to assess the level of contamination created to the land and the water inside these Bases.

If such evidence cannot be presented to the Missile Defence Programme Environmental Impact Survey, how can it be taken into consideration?

Within the UK no official body with oversight responsibilities to monitor development abuses on the US Bases exists.

- **Unlawful Unauthorised Developments: the Environmental Impact**

There have been a number of instances where we have brought abuses of planning process to the attention of the relevant local government authorities and the UK Ministry of Defence. These include for example:

Fylingdales:
The security fence (and unauthorised internal perimeter police patrol road) on the southwest side of the Base unlawfully encroached outside the boundary of the Base onto land held by the Forestry Commission.

The Under Secretary of State for Defence was obliged to remedy the position by a transfer of land.

Menwith Hill:
The security fence in the Main Gate area unlawfully encroached onto the highways' verge outside the boundary. The fence had to be removed and reconstructed.

It is unacceptable that the UK authorities turn a blind eye towards unauthorised developments and it it incumbent on members of the public to have to complain.

- **Maintaining the Security: the Environmental Impact**

The Bases are acknowledged to be targets for 'terrorists'. The security of the Bases is totally ineffective and costs the USA and UK a considerable sum to maintain. Menwith Hill and Fylingdales bristle with razor-wire-topped high security fences, CCTV cameras, intruder alarm systems, and are constantly patrolled by armed police and guard dogs.

The UK Ministry of Defence Police Officers are ostensibly the defenders of the Bases. It is impossible for these Police Officers to secure the Bases, even were their numbers to be increased. Their main function is for propaganda purposes, to convey the impression that they are guarding UK facilities, which impression is reinforced in the Courts when they prosecute peace activists. The UK Government has admitted that at Menwith Hill they are actually paid for by USA, which not only reimburses the UK Government for personnel salaries and expenses, but also purchases and maintains their patrol vehicles and buildings.

The occupation of Menwith Hill by over 100 Greenpeace protesters in July 2001 revealed just how inadequate was the security. The response was to upgrade the security by installing more of the failed systems and increasing the police numbers.

The following public concerns have been reported in the local media:

- Councillors fear the consequences to the local community of an attack on Menwith Hill, particularly the consequences of a 'dirty bomb' on the environment and human populations.
- The Emergency Services would be unable to cope with a 'terrorist attack'.
- In November 2001 a hoax Anthrax scare at the Harrogate Postal Distribution Office was dealt with by the Emergency Services and disrupted postal deliveries. The hoax demonstrated how vulnerable the supplies and services to the Bases are to 'terrorist attack'.
- The consequences to the locality from a shower of missile debris produced by collision between ICBM and an interceptor missile.
- The cost to the local taxpayers of providing additional, civilian North Yorkshire police to patrol the Bases.

- The crime-wave in cities such as York attributed to the deployment of the civilian police to patrol the Bases.
- The recreational amenities, Yorkshire Dales' and North York Moors' tourist attractions, are patrolled by armed police.
- Protest actions will be stepped up with consequences for the local community, e.g. blockading traffic.
- Human rights and civil liberties are infringed by application of the Terrorist Act 2000, for a radius of ten miles surrounding Fylingdales and five miles around Menwith Hill, (e.g. s. 44 gives the police the right to stop and search any person without cause for suspicion) and by clandestine closed circuit television monitoring of the roads and surrounding countryside.

- **Logistics: the Environmental Impact**

The Bases are dependent on the support of the host nation. Their operations could not function without the logistics infrastructure, e.g. transport of supplies of water, food, electricity and disposal of sewage and garbage and a local workforce to service the Bases. All these impact on the environment external to the Bases. All are vulnerable to disruption (e.g. Some of the local workers are members of Trades Unions. The British Trades Union Congress of 2002 passed an anti-'Star Wars' resolution, condemning US Missile Defence).

Peace protesters have blockaded, and can be expected to continue to blockade, access roads to Menwith Hill, which obstruct movement of personnel and supplies into and out of the Base. Blockades have generated TV coverage allowing a platform for presentation of the arguments of the protesters.

In order to ensure that the essential services continue to be provided, it is politic for the Station authorities to maintain good relations with the host national government and the local community. Public relations' propaganda 'sells' a benign and positive image and conceals any information, which might reflect adversely on the Bases and their personnel.

Currently the UK national and local authorities collaborate in the practice of a deception to keep the public ignorant, complacent and co-operative (e.g. describing Menwith Hill as a 'Royal Air Force' Station is a blatant propaganda hypocrisy, intended to persuade people to believe that it is British and thus playing an essential role in the defence of the realm). Thus the UK State is complicit with the illegal operations at Menwith Hill.

- **The UK State's Collusion with US Bases: the Environmental Impact**

In a democracy the people elect their representatives and expect them to make decisions and appoint public servants to manage the State in the best interests of the electorate. If financial and other resources are expended on support for the US Bases, it follows that those resources are not available for investment in the environment (e.g. the North Yorkshire Highways' Authority must provide and maintain roads to and from the Bases, which are not necessarily of benefit to the wider community).

The collusion is not confined only to the legislative and executive arms of the State, described herein, but is also supported by the judiciary.

The Judiciary's support for the UK Government:
One example serves to illustrate that, not only is the UK Government aware of the illegalities perpetrated, it is prepared to condone them and its actions are supported by Her Majesty's Judiciary.

Appeal: Helen John and Anne Lee: York Crown Court, 2 – 5 September 1997

The Court was obliged to examine the appellants' defence accusation that the Secretary of State for Defence acted in 'bad faith' to protect and support illegal activities at Menwith Hill (the UK Ministry of Defence was the prosecutor not the defendant).
The judge rejected the argument on the grounds that the appellants were denied the right to question the Defence Secretary in the Courts about his actions. He is protected by 'Parliamentary Privilege'. The appellants won the case not on the 'bad faith' argument, but on the fact that the Defence Secretary acted ultra vires - beyond the statutory powers of his office.

In his Judgment issued on 5 September 1997: the late Judge Jonathan Crabtree stated:

"It is said that wholesale breaches of the Interception of Communications Act 1985 and of the European Convention on Human Rights must be going on [at Menwith Hill]…on the face of it, it rather looks as though Mrs Baird [Barrister] may be right in this contention…as a matter of law, the fact that some sort of illegality may be going on at a military base is not our concern. An illegality of some kind is doubtless going on...'

Under the cover of 'national security' the UK Government may impose a Public Interest Immunity Certificate to block disclosure of any prima facie evidence likely to be produced in Court, exposing the operations of the US Bases. Judge Crabtree attempted to prevent the presentation in Court of a statement by British Telecom – only to acknowledge that his efforts had been pre-empted by disclosure on the Internet.

The trial was a flagrant breach of Magna Carta: '*To no one will we sell, to no one deny or delay right or justice'*. King John, Runnymede, 1215.

The Local Government Authorities: abuse of Judicial Process:
The collusion between the US Bases and the local Council authorities is illustrated by the following example:

North Yorkshire County Council v WoMenwith Hill Women's Peace Camp women:
Eviction Hearings: Divisional Court: November 1997 – July 1999:

February 5th 1999:
It emerged during cross-examination of the North Yorkshire County Council 's Chief Highways Maintenance Engineer, who was under oath, that all documentary evidence relating to the local authorities' collusion with Menwith Hill had been deliberately withheld from the Court and the peacewomen respondents.

The judge, Hooper J, immediately adjourned the trial and ordered 'discovery', within one week, of all such correspondence. The Council 'discovered' 61 (sixty-one) relevant documents, which was still a limited disclosure. The correspondence revealed that the instigators of the eviction proceedings were the Menwith Hill Station authorities and that the Council Officers had discussed the possibility Menwith Hill making a financial contribution to the costs. (As there were five hearings in the High Court over a period of 20 months, the costs amounted to a substantial sum, believed to be in excess of £30,000).

The peacewomen submitted further affidavit arguments asserting that the national and local governments are fully aware of the illegal operations at Menwith Hill. The North Yorkshire County Council was thus guilty of bringing a case 'with unclean hands', by their covert unlawful collusion with the US National Security Agency in command of Menwith Hill.

This argument did not affect the Judgment.

Although the High Court had also to examine the peacewomen's right to protest, as enshrined in the Human Rights' Act 1998, the right to live outside Menwith Hill was not upheld and the Peace Camp was evicted on 19 August 1999.

In defiance of the High Court Injunction ordering peacewomen not to reside outside Menwith Hill, Helen John re-established the Women's Peace Camp on 24 May 2004.

- **Maintaining the Secrecy: the Environmental Impact**

Considerable finances and resources are diverted from investment in the UK environment and expended to maintain the secrecy of the US Bases' operations. It is not possible for members of the public to calculate the UK Government's contribution to the support for the US Bases provided by the Security Services and the Government Communications Headquarters. It is assumed to amount to hundreds of millions of pounds.

Some indication of Britain's commitment has been revealed by major exposures, over the past 20 years stripping away the layers of secrecy. They include:

- *The Unsinkable Aircraft Carrier*, Duncan Campbell, 1984
  (The definitive research into the US Bases).

- *The Hill*, TV programme produced by Duncan Campbell, 1993
  (Based partly on information amassed from perusing Menwith Hill's garbage).

- *Uncle Sam's Eavesdroppers*, TV programme produced by Richard Saddler, 1998
  (Duncan Campbell exposed that US Missile Defence components were being installed in Menwith Hill)

- *Interception Capabilities 2000*
  (Report presented by Duncan Campbell to the European Parliament's Committee of Inquiry into the implications for Europe of the US controlled ECHELON interception network).

- *Report of the European Parliament*, 5 Sept 2001
  (The EP made recommendations that the British and German Governments implement oversight and monitoring of the USA's communications' interception activities).

- Lots of articles published in the press – too numerous to mention.

- **Extra-Parliamentary Protest Activity: the Environmental Impact**

The effectiveness of 'single-issue' pressure groups' political activity, especially when it succeeds in changing attitudes, and thus policy decisions, at national and local government level should be a prime consideration for the Missile Defense Agency. For example, the Greenham Common Women's Peace Camps were instrumental in the decision to cancel the land-based, nuclear-armed Cruise Missile programme – as a consequence of which the US Base closed and environmental restoration work is underway.

The Yorkshire CND website http://cndyorks.gn.apc.org carries a comprehensive overview of the many different campaigning strategies deployed in opposition to the US Bases. All of them, including the non-violent civil disobedience actions, such as blockades, have an immediate impact on, and by influencing policy, the potential to change the environment.

The influence for change these opposition campaigns have achieved is difficult, if not impossible to assess, yet it is evident that changes in attitude have occurred and that they directly result from the presentation of an alternative viewpoint (e.g. the media now routinely describes Menwith Hill as 'US Spy Base').

One example will serve to illustrate:
In early 2001 approximately 200 people sent representations to the Harrogate Planning Department objecting to a development on the grounds that it was intended for US Missile Defence.

Because the Planning Application did not go before the elected Councillors, the first they knew of the plans and the objections was when it was reported in the Press that campaigners had approached a local Member of Parliament, who had then raised it with the Secretary of State for Defence.

In consequence Harrogate Council's Chief Executive, on behalf of the Council, wrote to the Prime Minister to insist that the Council be kept fully informed of the implications of such developments. The Council demanded further information about the implications of Menwith Hill's US Missile Defense role for the local community. In October 2001, Councillors and Executive Officers from Harrogate Borough and North Yorkshire County Councils were invited to attend a meeting with top Civil Servants at the Ministry of Defence in Whitehall, London.

The Council representatives were given blatant propaganda assurances that Menwith Hill is considered to be of the highest importance for the UK's national defence. The Minister of State for the Armed Forces repeated verbatim parliamentary and public statements his predecessors have issued. These assured the local authorities that Her Majesty's Government is aware of all activities taking place at the Bases: that UK personnel are integrated at the highest level and that the Bases are not engaged in anything inimical to British interests.

Tony Benn, a former Cabinet Minister, as Secretary of State for Energy at the highest level of responsibility for the nuclear power programme, stated that government Ministers are the 'elected ignorant' – so little 'sensitive' information was divulged to him when in Office.

US Missile Defence: an unpopular programme

British public opinion has changed radically as a result of the publicity generated by the anti-'Star Wars' campaigns. An opinion poll conducted in the summer of 2001 revealed that nearly 70% of the British people opposed 'Star Wars'. At the same time 278 Members of Parliament signed an Early day Motion calling for a full debate in the House of Commons.

Recent polling indications suggest that the opposition is growing.

Subject: Comment on MDA Draft Programmatic Environmental Impact

Dear Sir/Madam:

This is a letter for the record in comment on the MDA PEIS.

It is my opinion that there is absolutely no way that we can accept "Alternative 2, missile defenses with space-based weapons." This is just too dangerous and a major risk to our democracy and the stability of the world.

We are also not very happy with "Alternative 1, missile defenses without space-based weapons." This alternative also will destabilize world weapons systems manufacture and deployment and lead to dangerous systems that can get into hands of empire builders or madmen bent on ruining the earth for us all.

Alternative 3, "No Action," which might seem like a logical out for those wanting to suppress this race to destruction, seems to leave things as they are - i.e. would allow continuation of the present programs which we are against! So the PEIS should be rewritten to allow another alternative: Discontinue all work on such systems, and work on getting cooperation throughout the world on disarmament.

Space based systems will most likely require nuclear energy in space and that would lead eventually to environmental disaster. or at least more widespread nuclear material throughout the earth biosystems.
This is not a good prospect for the survival of life on earth.
Furthermore, defensive space based systems can easily be used for offense; this is equally dangerous. It could also lead to control of space and the world by one country or controlling interest. And although it is evident that the Pentagon has for many decades wanted to do just that, and probably has a secret such goal, it is not what the people of the USA should allow their government to do in the interest of life on earth.

Furthermore, the cost of researching and building these systems is extremely high, and the money should be used to prepare for the coming resource depletion: fossil fuels, water, soil, air, and other resources we need to survive. That preparation will necessarily include bringing up the level of living standard of others on earth so that they will want to reduce their number of offspring and thereby stabilize the earth's population. That is on top of all the other things that need to be done: find new energy sources/systems, replacement for dwindling mineral resources, cleaning up of pollution in our air, water, soil, and organic systems.

All in all, although I realize and understand the logic of wanting impenetrable defenses, the survival of life does not depend on those; instead it depends on all countries and peoples of the earth cooperating on bringing our use of earth's resources under control so all can live a comfortable and safe life on earth. For too long the people of this country and of the world have allowed the military mentality - a kind of mocho growing up mentality - to dominate the agendas of the earth. Of course some military is necessary as a safeguard, but it has been way overdone. We must slowly and carefully get back to a rational approach to living at peace on the earth. And to start we must not continue to expand these MDA programs.

Thank you for including these comment in the record. I wish more people would think about the direction we are headed in these programs.

Sincerely, Filson H. Glanz

To: mda.bmds.peis
Subject: Pentagon Star Wars Plan

As a physiological psychologist, I am deeply concerned about the environmental and public health impacts of the Ballistic Missile Defense System, and wish to comment on the Draft Programmatic Environmental Impact Statement (PEIS).

<!--[if !supportEmptyParas]-->

In particular, I am concerned about the hazardous waste associated with the system. For example, perchlorate from rocket fuel has already contaminated rivers and ground water, and can find its way into milk supplies (e.g., as has occurred in Texas). Like other toxins that act as endocrine disruptors, perchlorate can interfere with thyroid hormones and disrupt pre- and post-natal brain development, resulting in reductions of IQ and attention, mental retardation, hearing loss, and defects in speech and coordination. Seventeen percent of children suffer from developmental and learning disabilities, and as many as 25% of those disabilities are due to the effects of environmental toxins either acting alone or in combination with genetic and other environmental factors.

<!--[if !supportEmptyParas]-->

Certainly, those individuals (often consisting of minority ethnic groups) and non-human species who live on or near test sites are at particular risk, and this issue is not sufficiently addressed in the PEIS. Finally, it would be environmentally catastrophic if these weapons were ever actually used in war. The hazards of use, including high altitude nuclear explosions, are not discussed in the PEIS but should be addressed. .

Weaponry escalation only serves to undermine security by creating new enemies and furthering fear and distrust. I thus urge you to oppose continuation of this development plan. Thank you for your time.

to. MDA BMDS PEIS, c/o ICF Consulting

(1) The most fundamental flaw in the logic behind this program as outlined in the PEIS is that rather than enhancing our security it is highly likely to decrease it. Recent events really should make this obvious even to the neocons. Why is North Korea working so hard to build more nuclear weapons? Why does Iran appear to be working toward the capability of building nuclear weapons? Why are a number of countries developing rockets with longer ranges and to carry heavier loads? Why does China appear to planning to modernize their missiles (now liquid fueled?). We have no doubt that the most basic reason is for DEFENSE against this extremely provocative planned Ballistic Missile Defense System. Unless convincing rebuttals can be made to the above this entire program should be stopped.

(2) Beyond the question of the BMDS making us less secure it will also either bankrupt this country completely or at least divert badly needed monitory AND TECHNICAL resources from pressing human needs.

(3) In addition the BMDS program can not avoid causing serious environmental harm to an environment that is already badly stressed.

Of particular concern is with the spaced based proposals, they obviously need large amounts of power and we are well aware of the development work already going on to develop fission nuclear power plants for use in space. This is fundamentally a crazy idea. We dare anyone to prove otherwise!

(4) Calling this system a 'defensive' system in Orwelling double speak, it is and can only potentially be effective as an offensive system. Why not be honest and tout it as such. Some publications, such at the Space Command's Vision for 2020 clearly states that a space based system would be used to"deny other nations the use of space" IS THAT DEFENSIVE OR OFFENSIVE ? Why wouldn't other countries see it as offensive and a further attempt by the U.S. to dominate the rest of the world.

(5) For all of the above, and many more, we believe that the only acceptable alternative is for NO BALLISTIC MISSILE SYSTEM AS OUTLINED IN THIS PEIS. Note that does not mean the 'no action alternative' IT MEANS NO PROGRAM.

(6) The positive alternative would be a very vigorous effort to lead the entire world into international cooperation to eliminate all weapons of mass destruction and to forever to prohibit any weaponization of space.

Submitted via email by Dale Nesbitt for East Bay Peace action. This statement approved by the EBPA board on 11-11-04.

Subject: "Star Wars"

The proposals for missile defence are dangerous and misleading. To describe such a system as "defensive" is disingenuous: it is a shield, and the use of a shield is to protect the wielder of a sword. Whether or not this is the real purpose of the missile defence system is irrelevant: it will be seen as such by other nations who have reason to fear the might of the USA, and will respond by developing their own weaponry in such a way as to get round the shield. There will be an arms race, in other words. In a world already thoroughly stocked with nuclear weapons, nothing is more calculated to provoke a disaster.

The idea of the domination of the earth from space, of which "Star Wars" is a component, is morally quite unjustifiable and in fact monstrous. It offends one of the most profound human feelings, the association of the sky with spirit. I do not imagine, however, that such considerations weigh with military planners.

I do not want to live in a world in which missile so-called defence is a reality, and I do not want my country, in which there are quite enough American military bases already, to host missiles, radars and communications systems for it. I do not believe that having them here will contribute to our security one whit, rather the reverse, and I repudiate my government's endorsement of the scheme. I believe that most British people would agree with me if they were in possession of the facts, but great care is taken to ensure that they are not. This vital issue has never been debated in Parliament.

Since it appears that "no action" in this context means "carry on with the plan", the three alternatives being considered by PEIS are all unacceptable. "Star Wars" in any form is destabilising, will eat up huge amounts of money that are needed for education, health care and the alleviation of poverty, will further distort the budget not only of the USA but of many other nations in favour of military spending and thus will make more likely a preference for military as opposed to peaceful solutions, and will only worsen the pollution and destruction of the planet by military-related industry and the cluttering up of space with bits of debris. No-one can have had a worse idea than this for many years.

Subject: MDA PEIS Form Responses

name=Robert Howd
org=Office of Environmental Health Hazard Assessment
address1=1515 Clay St., 16th floor
address2=Oakland, CA 94612
comments=In the draft Programmatic Environmental Impact Statement for the Missile Defense System (1 September 2004), I would like to point out incomplete and misleading statements about perchlorate toxicity and standards in the bottom paragraph on Vol. 1, p. 4-56. This discussion provides the viewpoint of the DoD and the Perchlorate Study Group, an Industry Workgroup, on perchlorate toxicity, but ignores all risk assessments conducted by actual risk assessment agencies. The U.S. EPA has been evaluating perchlorate toxicity for years, in association with several defense agencies (as stated), and has released a draft risk assessment which proposes a drinking water equivalent level of 1 ppb.
The State of California Office of Environmental Health Hazard Assessment has published our risk assessment which estimates a health-protective level of perchlorate in drinking water of 6 ppb. The State of Massachusetts has recently released their evaluation with a recommended drinking water level of 1 ppb to protect pregnant women and fetuses (or other sensitive sub-populations), and 18 ppb for healthy adults. The U.S. EPA guidance applicable to water contaminant plumes emanating from industrial and DoD sites has used a standard of 4-18 ppb for several years.

To not consider and apply these relevant and applicable standards to the evaluation of potential environmental impact of the deployed missile systems seems to me to be putting both the DoD and the public at risk, both from legal liability and potential chemical hazards. I recommend that this section of the report, and any financial and toxicological calculations based on it, be revised to include the viewpoints expressed by the regulatory agencies whose job it is to regulate the public and environmental exposure to perchlorate. Acknowledging these opinions need not wait for the finalization of the U.S. EPA's current draft risk assessment for perchlorate, currently under review by the National Academy of Sciences, nor the promulgation of the California Maximum Contaminant Level for perchlorate in drinking water, scheduled for 2005.

Thank you for consideration of these comments.

Robert A. Howd, Ph.D.

The above comments represent my personal opinions, and have not been reviewed or approved by OEHHA prior to submission.

Subject: Comments on the BMDS PEIS

Here are additional comments on the BMDS PEIS

1) In category after category, case after case, the PEIS repeatedly discounts the impacts of toxic substances resulting from and involved in activities at every level - manufacture, launching, use, etc. - by contending that the toxic substances will have no impact because they will be handled in accordance with existing law and guidelines. Such a blanket contention flies in the face of current experience with toxic substances. Many factors result in the legal guidelines failing to insure public and environmental safety when toxic substances are involved.

The report fails to entertain the possibility of accidental spills and discharges, whether in the transportation stage or as a consequence of mishaps at other stages. Additionally, the report ignore our experiences in which we have repeatedly experienced toxic consequences from currently legal uses of chemicals. The claim that there will be no toxic impacts by merely following existing handling rules is implausible.

Moreover, new discoveries about the minute amounts of substances that can still have a deleterious effect are continually forcing us to readjust safety standards. To initiate the massive undertakings proposed within the BMDS without making any attempt to mitigate the impacts - readily imaginable based on the evolving nature of toxin safety understandings - is unrealistic.

2) The PEIS completely ignores the well known environmental impacts of radiation. It does so by maintaining the transparent fiction that an effective BMDS can be implemented without resorting to the use of nuclear war heads.

Current research with BMDS prototypes provides scant basis for the belief that lasar or kinetic weapons will serve to eliminate target warheads. A realistic PEIS for BMDS must include a full and detailed consideration of the environmental impacts of nuclear weaponry. Such an assessment must address the entire nuclear cycle - production and manufacture as well as decommissioning and waste storage.

Yorkshire Campaign for Nuclear Disarmament comments on the Draft Programmatic Environmental Impact Statement for the Ballistic Missile Defence System

Introduction
The Yorkshire Campaign for Nuclear Disarmament is a regional wing of British CND and it specialises in Missile Defence issues. It is one the leading UK Non-Governmental Organisations campaigning on Missile Defence, with particular emphasis placed on the two Missile Defence bases in Yorkshire – Fylingdales and Menwith Hill (the latter is yet to be officially confirmed as a Missile Defence facility).

Given our considerable interest in Missile Defence and its implications for global and UK security and stability, Yorkshire CND welcomes the opportunity to present our comments on the Draft Programmatic Environmental Impact Statement.

We are disappointed however that the PEIS will only be undertaken for component bases in the United States and not for overseas bases integral to the system, such as Fylingdales. From our experience of talking to the residents close to the Fylingdales base, we are aware of a constant concern about its role in the "Son of Star Wars" program and a desire for more information and accountability from the developers of the system. The local population in the vicinity of this base has both environmental and security concerns regarding the base's role in Missile Defence that ought to be addressed in such a study. The same also applies for Menwith Hill – considered highly likely to play a key role as the Ground Based Relay Station for the Space Based Infra Red System - and these concerns will grow if the United States is granted permission to use the base for Missile Defence by the UK Government.

Furthermore, there exists a large, informed section of society, not necessarily within the vicinity of these particular bases, that is also legitimately concerned as to the potential impact on UK and global security as a result of the Missile Defence system. Despite the UK's involvement in the system this group too will not be represented by this study.

Yorkshire CND, along with many concerned UK groups, did present submissions to the UK Parliament Defence Committee in late January 2003 as part of their investigation in to the potential use of Fylingdales for US Missile Defence, especially as the Ministry of Defence has repeatedly stated that it does not consider that the UK was under threat from a missile attack. However, since the public consultation period declared by the Secretary of State for Defence at the time (one month over the Christmas holidays and parliamentary recess) was completely inadequate, it gave no real opportunity for local residents or the general population of the UK to voice their concerns on this important issue. We hope therefore that the PEIS will give due attention to the views and concerns of residents affected by Missile defence beyond the shores of the US mainland.

Despite the fact that the PEIS has currently declared that it will only consider component bases of Missile Defence based in the US, we will refer to the Yorkshire bases both in the hope that the PEIS will recognise the importance of expanding its remit to cover Missile Defence bases beyond the USA mainland, and partly because the concerns that surround these bases can be equally applied to their US-based equivalents.

UK position
The UK Government has already granted permission for the USA to upgrade the Early Warning Radar at Fylingdales so that it may play a role in the Missile Defence system. Concerned observers of Missile Defence developments expect a similar request for use of Menwith Hill to come from the US in the future. The base has purpose-built downlink and relay elements for the Space-Based Infra-Red System (SBIRS), which will be integral to the US Missile defence system if and when the SBIRS satellite network

is complete. It is also possible that the UK may host an X-Band Radar and/or Missile Defence interceptor missiles in the future.

Fylingdales
Fylingdales, and radars like it, present environmental concerns to the local population as a result of the possible harmful biological effects of the non-ionising radio frequency emissions from the radar. Whilst the radar beam itself projects 3° above the horizon, the beam releases leakage in the form of sidelobes. These sidelobes of pulsed low frequency radiation are the source of considerable anxiety to local residents. Such concerns are exacerbated by the obvious effects of the radar in the local area (such as car alarms being set off regularly for no apparent reason, car automatic locking systems being triggered and interference with radio and tape players in cars passing the base) and the knowledge that the similar Cape Cod radar base in the United States has seemingly significant cancer clusters in its vicinity (that has resulted a USAF supported study of the radar effects on health). In 2003 the then base commander of RAF Fylingdales confirmed to Yorkshire CND that the radar has "issues with leakage."

The paper "Is it Safe?" by Professor Dave Webb - Convenor of Yorkshire Campaign for Nuclear Disarmament – explains in more detail the environmental concerns over the radar radiation and it is attached as Appendix 1 to this paper.

Furthermore we would point out that the Fylingdales radar base is in the North York Moors National Park – a loved and protected area of the UK. It is already seen by many as an unsightly abomination cutting across the horizon of otherwise ancient and unspoilt moorland. An increased role for the base in a new, highly controversial global military network presents the potential for increased activity, expansion and increased policing, all of which will lead to environmental degradation of the moorland on which the base is situated and the surrounding countryside.

Menwith Hill
Menwith Hill overlooks but is excluded from the Nidderdale Area of Outstanding Natural Beauty. As with Fylingdales, it interferes with a region that has been specifically ~~pinpointed~~ as an area of special importance that deserves protection. The land the base is on would no doubt have been included in the area if it had not been already spoilt by the considerable military presence. Menwith Hill is again visible for miles around and is an inexcusable blot on an otherwise precious landscape. The base's continual expansion and glaring nightlights only further interfere with this area.

Deleted: pinponted

Despite the base's contention that it is an RAF base, the base is in all reality run by the US military and it is famously unaccountable to the UK people. Thus, its environmental impacts are less controllable and have become considerable. As an example, although the base does present planning applications to the local council, that council has no power to disapprove them and the base can build whatever it desires, where it desires, with the local community only being able to express its concern and hope that the base commanders will take some notice. This situation has led to fervent expansion with little or no consideration for the impact on the local community or environment.

The discovery of a colony of rare feral orchids in natural wetland on the north-west of the Base by Anne Lee of the WoMenwith Hill Women's Peace Camp(aign), led to an investigation by one of the country's top orchid experts. This research did lead to the re-routing of a proposed high security fence and an agreement to conserve the orchids' site as a reserve. Such protection would not have been achieved if it were not for the discovery of a concerned citizen, since the base itself makes little effort to consider the environmental impact of its proposed developments.

Space
Missile Defence plans extend to the possible deployment of space-based weaponry and space-based weapons systems. It is crucial that the PEIS consider seriously the likely impact of space weapons deployment. The use of space weapons, for whatever reason, to attack or destroy objects outside of the atmosphere would produce space debris, changing the near Earth environment and would become a serious hazard to future space missions, even possibly preventing them from leaving Earth. At the speeds required to escape the Earth's gravitational pull, the impact of just a tiny object on a space rocket could be disastrous. Space-based conflict of any sort could add to this problem enormously and it is an issue that deserves serious attention.

Further to this, plans for weapons such as the space-based laser may eventually incorporate the use of nuclear power. The deployment of nuclear powered satellites could be environmentally disastrous with considerable risk of high-level pollution at the point of initial launch, when in orbit (from attack or accident) and (if and when the orbit decays) during re-entry into the Earth's ~~atmosphere.~~

Deleted: atmosphere .

The deployment of space-based weapons will also present the problem of increased global instability and a degradation of arms control efforts. Such deployments are likely to provoke other states to respond in kind with their own developments and deployments. With no sufficient legal system controlling the non-WMD weaponisation of Outer Space, weapons deployment and the threat of opponents interfering with vulnerable ~~systems,~~ could provoke a highly destabilising and dangerous space arms race. On top of this, space weapons deployment could provoke both horizontal and nuclear proliferation amongst states that are not capable of entering such a space weapons race but wish to respond to the threat.

Deleted: systems .

Despite the PEIS's claims, various weapons components deployed under Missile Defence will have offensive capabilities, taking war-fighting to a whole new level, quite literally. Such statements are justified by statements from official US sources, such as the US Space Command's "Vision for 2020", their "Strategic Master Plan FY06 and Beyond" and the USAF Doctrine Document 2-2.1 "Counterspace Operations".

Nuclear proliferation and a space arms race would have considerable, long-lasting effects on arms reduction efforts and international stability and, from the perspective of the PEIS, present a genuine threat to the Earth's environment through the production of nuclear weapons, the creation of space debris and the possible use of nuclear weapons.

Other issues
The exhaust plumes of missile like the Missile Defence interceptor create considerable toxic pollution which is having an under-rated and very important long-term effect on the Earth's Ozone Layer. Such effects are to be seen increasingly over the coming years and could have a massive environmental and social impact in the near future. Missile Defence developments will expand the amount of rockets being sent into space and exacerbate this problem.

Yorkshire CND considers it worth emphasising too that the Missile Defence system is currently costing the US taxpayer something in the region of $9 billion every year and that this is likely to rise as deployment of more and more complicated, high-tech systems takes place, alongside maintenance of the current set-up. This amount of money could be diverted so that further cuts in health care, education and public services budgets would not be necessary. The money could be used too for broader, longer-term, more realistic, sustainable security efforts such as the cancellation of third world debt or the provision of food, water, shelter and education to some of the world's poorest people.

Yorkshire CND asks that our concerns be taken seriously and considered properly. The PEIS has offered itself three options, none of which is sufficient. As we understand it, the "no action" option simply allows for no change in current developments and the continuation of the project. If this is to be the ultimate step that the MDA is prepared to take then it implies a bias towards the outcome of this PEIS study by not allowing for the possibility that the Missile Defence system is too environmentally destructive to continue with.

The Missile Defence system is indeed a hugely expensive, dangerous and, on many levels, environmentally destructive system that is absorbing funds that could be put to better use in the challenge of global security. On these grounds, it should be halted.

Yorkshire CND would appreciate notice of receipt of this paper and to be kept up to date with developments relating to the PEIS.

APPENDIX 1

Fylingdales - Is the Radar Safe?
By Prof. Dave Webb – www.cndyorks.gn.apc.org/fdales

An Information and Safety Booklet given to contractors, new personnel and visitors to the Phased Array Radar (PAR) at RAF Fylingdales in North Yorkshire tells them to keep their mobile phones switched off to protect them from damage from RF power. The booklet also warns that there is a risk of induced RF power causing a spark between car and metal petrol cans and that remote car locking devices may not function. However, it doesn't mention much about the risk to health of visitors or local residents.

RAF Fylingdales is in the North Yorkshire Moors National Park and has been the home of a US Ballistic Missile Early Warning System (BMEWS) since the Cold War days of the 1960s. The base is run for the US by the RAF and is one of the 3 stations in a chain linked across the North Atlantic. The other stations are Thule in Greenland and Clear in Alaska and the 3 stations provide (in conjunction with the Defense Support early warning satellites) a Tactical Warning/Attack Assessment directly to the US Joint Chiefs of Staff.

The 40-meter high truncated pyramid that forms the PAR has 3 faces each containing an array of 2,560 aerials, transmitting at 420-450 MHz with a total mean power output of 2.5 Megawatts a range of around 3000 miles and is able to operate over a full 360°. The main radar beam is directed to be at least 3° above the horizontal, however side lobes can reach the ground.
At the time of the PAR upgrade to the system (previously it consisted of three mechanically steerable dishes housed in radomes) in 1993, an ElectroMagnetic Radiation (EMR) Survey of the area surrounding Fylingdales was commissioned by the Nuclear Free Local Authorities [1] . The survey was an extension of an earlier report produced in the summer of 1991 and used 23 measurement sites, including moorland paths and tracks, roadside locations and habitations. The survey found maximum field values of about $10Vm^{-1}$ which were in fact quite close to the currently accepted international standards developed by the International Commission on Non-Ionizing Radiation Protection (ICNIRP) reference levels of $28\text{-}29Vm^{-1}$ for the Fylingdales frequency range [2] . The MoD says that "UK safety thresholds are based on NRPB guidelines and not those of ICNIRP" [3] . However, the European Council Recommendation 1999/519/EC requires member states to implement ICNIRP and their power levels are more than ten times lower than NRPB in this frequency range [4] .

Also, there is some question as to the characteristics of the radar beam generated by the thousands of antennae on the PAR. Beams generated by conventional radar are in the form of simple waves, whereas the PAR beam is generated by many overlapping pulses that can strike a person thousands of times in a fraction of a second.

Some investigation into the accepted international standards is required in order to put these results into some kind of context. A recent report on the Physiological and Environmental Effects of Non-ionising Electromagnetic Radiation for the European Parliament [5] states:

"What distinguishes technologically produced electromagnetic fields from (the majority of) those of natural origin is their much higher degree of coherence. This means that their frequencies are particularly well-defined, a feature that facilitates the discernment of such fields by living organisms, including ourselves. This greatly increases their biological potency, and 'opens the door' to the possibility of frequency-specific, non-thermal influences of various kinds, against which existing Safety Guidelines – such as those issued by the International Commission for Non-ionising Radiation Protection (ICNIRP) - afford no protection. For these Guidelines are based solely on consideration of the ability of radio frequency (RF) and microwave radiation to heat tissue, and of extremely low frequency (ELF) magnetic fields to induce circulating electric currents in the interior of the body, both of which are known to be deleterious to health, if excessive."

The report points out that the frequency-specific sensitivity of living organisms to ultra-low intensity microwave radiation was discovered over 30 years ago in Russia and there the exposure guidelines are approximately 100 times more stringent that those of ICNIRP. It also notes that some symptoms have been reported in epidemiological studies involving humans, animals and plant life connected with a radar operating at 154-162MHz, with a pulse repetition frequency of 24.4Hz - at a location where the intensity of the emitted radiation is comparable to that typically found at 150m from a base-station. Additional effects include [6] :

- Depressed nocturnal melatonin levels in cattle [7] .

- Less developed memory and attention span (as well as decreased endurance of their neuromuscular apparatus) of children living within a 20 km radius of the radar, subject to a maximum exposure of 0.00039 W m^{-2}.
- A six-fold increase in chromosome damage in cows exposed to a likely maximum intensity of 0.001 W m^{-2}.

(The cited field intensities are estimated from information on the electric field intensity as a function of distance from the radar installation [8]).

The Fylingdales radar operates by emitting a series of pulses and additional, perhaps more serious, problems may arise at frequencies around 17 Hz. As mentioned in the STOA report, this lies in the range of beta brain-wave activity and is close the frequency of a flashing visible light that can provoke seizures in people with photosensitive epilepsy. It is also the modulation frequency at which *"there is a maximum in the expression of calcium ions from brain cells when they are irradiated with amplitude modulated, low intensity RF radiation over a wide range of carrier frequencies"* and *"any interference … could well undermine the integrity of the whole nervous system, although the extent to which this actually occurs is, at present uncertain, owing to a lack of the necessary research."* The pulse repetition frequency of the radar is thought to be 27 pulses per second (at least, this was the documented frequency of the previous system [9]) and it is not known whether there are any similar effects at or around this frequency that need to be examined closely.

Concerns about the effects of the electromagnetic radiation effects due to the radar were expressed by Yorkshire CND in its submission to the House of Commons Defence Committee on the upgrading of Fylingdales for the US Missile Defense Program (*See First Report of Session 2002-3 Volumes I & II, HC 290-I and HC 290-II, published 29 & 30 January 2003*). In response the MoD published for the first time results of emr levels measured around the base from 1991. These records show typical recorded levels of around 0.230 mW/cm^2 which is comparable with the reference level suggested by the ICNIRP of 0.225 mW/cm^2 for 450 MHz radar signals.

Radar power levels can be quoted as field strengths (V/m) or as power densities (mW/cm2). It is general practice amongst those who want to show how low their emissions are to quote in power density since this is proportional to the square of field strength, and therefore levels that are, say, ten times lower than the limit in volts per metre will be 100 times lower if expressed in mW/cm^2.

The maximum recorded levels are around 0.869 mW/cm^2 (location 26, Top of outside perimeter fence). This is 33% of the NRPB power density level or 58% of the NRPB electric field level. However, it is 4.3 times the ICNIRP power density level or more than twice the ICNIRP voltage level.
In the report the MoD state:

(para 4 on p. Ev60) "It should be borne in mind that UK safety thresholds are based on NRPB guidelines and not those of ICNIRP..."

In fact the UK has failed to implement legislation based on the European Council Recommendation 1999/519/EC, which requires member states to implement ICNIRP safety thresholds (which are ten times lower than NRPB in the frequency range relevant to Fylingdales).

Cape Cod
In April 2001 the US Air Force agreed to conduct "time-domain measurements" on a similar radar installation (known as PAVE PAWS – Phased Array Warning System) at Cape Cod in the US. Local residents there are concerned about the radar because the area has some of the highest rates of cancer in the state. From 1993 to 1997, nine of the Cape's 15 towns had breast cancer rates at least 15 percent higher than the rest of the state. [10]

Richard Albanese, an Air Force scientist for more than 31 years, and others (including Professor Kurt Oughstun) are worried that the radar's phased wave fronts affect human tissue in ways that aren't yet understood. Albanese is reported as suggesting that the radar station should be shut down or moved and that *"I have to go with the concepts of the medical profession, which say that humans shouldn't be exposed to physical or chemical environments that have not been tested'* . in the worst case the PAVE PAWS station could be causing a 21 percent increase in 'malignant disease' rates, a risk that would appear to warrant more study. *"In my experience working with military personnel ... misconceptions and*

errors tend to become entrenched in the organizational setting and do damage to medical practice" he wrote. [11]

In a presentation given in February 2002 at the start of a series of experiments to measure the PAVE PAWS radar, Albanese said he has conducted animal testing that has shown animals suffering harm when exposed to phased array radar at levels 1,000 times below the current electrical health standards. [12] The question remains "why has the Air Force classified much of Albanese's work?"

X-Band Radar
There may be additional problems. The UK government has already agreed that Fylingdales can be upgraded for use in the US missile defense ("Son of Star Wars") system and it is still possible that a new high resolution phased-array X-band radar (XBRs) using high frequencies (5.2-8.5 GHz) and advanced radar signal processing technology may eventually be employed at Fylingdales to improve target resolution [13] . These systems emit a series of electromagnetic pulses over a 50° field of view in azimuth and elevation, and can be rotated to track targets from any direction. When fully operational each system will include a radar mounted on pedestal, will need approximately 30 to 60 personnel to operate and will encompass an area of approximately 7 hectares (17.46 acres) for the radar alone and would need to be surrounded by a 150 m (500-foot) controlled area. [14]

XBRs have an average power of 170 kW and an antenna area of 123 m^2, which means a power-aperture product of about 20 million, but they usually incorporate a "thinned" array of only 1/5 of the total possible number of aerial elements (around 81,000) decreases the gain by a factor of 5. In this case more energy goes into the radar beam sidelobes but does produce a narrower beam and provides greater tracking accuracy.

Questions have been raised regarding the possible danger to the health of people living close to these installations. The BMDO insists that the microwave leakage from these high power radars is safe – but independent investigations into possible health hazards need to be made.

The XBR BMDO fact sheet [14] states that "The exposure limits established by [the US standard] ANSI/IEEE C95.1 1999 are used to ensure that public health will not be impacted by EMR emitted from the XBR".
Two major exposure environments are defined: inside and outside a controlled area of radius 150m. Security personnel would control the area to prevent any unauthorized access. It is claimed that outside the controlled area the EMR will be no higher than the power density levels specified in ANSI/IEEE C95.1 1999. The US Missile Defense Agency state that:
"There is a possibility that EMR may effect television reception out to a distance of 4 kilometers (about 2.5 miles) from the XBR and that occasional static may occur in some radios out to 7 kilometers (about 4.3 miles) from the XBR."

Concluding remarks
The radar at RAF Fylingdales in North Yorkshire gives rise to a number of concerns:

- The effects on health from the electromagnetic radiation need further investigation – a fresh EMR survey of the site is needed to update and re-examine the data collected 8 years ago – especially as the accepted international standards are being challenged in the US and by those concerned about the health effects of mobile phone masts etc.;
- The Ministry of Defence needs to explain why it insists on referring to NRPB guidelines rather than those of the ICNIRP (recommended by the European Union). Could it be because the Fylingdales radar fails the ICNIRP standards but not those of the NRPB ?
- More studies are needed on the extent and effects due to the low frequencies around the pulse repetition rate (27 Hz) as these may be particularly harmful to biological organisms;
- The introduction of a proposed X-band radar would mean an increase in EMR levels possibly resulting in an increased danger to local inhabitants and wildlife.

Much more research is required into the extent of EMR pollution at Fylingdales, the effects of these EM fields at the frequencies encountered and a much more in depth study of the health effects of the proposed X-band radar system.

9300 Lee Highway
Fairfax, VA 22031
(sent via web-page)

Attention: Public Participation Officer

Dear Sir or Madam,

This letter is to transmit comments on the draft Ballistic Missile Defense System Programmatic Environmental Impact Statement, dated September 1, 2004.

I write on behalf of the Los Angeles chapter of Physicians for Social Responsibility, the American recipient of the 1985 Nobel Peace Prize. Founded in 1980, the organization has approximately 5,000 members in Southern California. The two main principles of our organization are to prevent the use of weapons of mass destruction and preserve the environment. It is out of concern for these two tenets that we write.

CROSS-CUTTING ISSUES

With respect to what the overall BMDS actually could entail, the PEIS is so broad and generalized that it is not possible to know what is covered by the overall BMDS PEIS and what isn't. For example, nuclear-tipped interceptors have been discussed by MDA officials but are not addressed in this PEIS. The extent and limitations of this PEIS should be clearly stated.

Communities most impacted by BMDS have been largely excluded from the environmental review process. For example, communities near Vandenberg AFB will disproportionately bear the burden of the proposed 515 launches over the next ten years. And, the PEIS has not sufficiently dealt with the effect of cumulative effects in Southern California, as many of the region's contractors are working on the weapon system. Simply, there needs to be additional hearings in potentially impacted areas of the nation.

The timeline to release the Final PEIS – cited on the MDA web-site and announced at the October 19, 2004 public meeting – a mere two to six weeks after the comment period deadline portends that MDA will not fully consider and respond to public testimony. PSR-LA emphatically suggests that MDA take the time to consider and respond in full to all comments and critiques.

NO ACTION ALTERNATIVE

DC_E0395

What is called the “No Action Alternative” is not adequate under NEPA and does not describe a scenario where no action is taken. Rather it describes a situation where the Missile Defense Agency would continue existing development and deployment of missile defense systems unabated. Under the “No Action Alternative” individual systems would continue to be tested and deployed except for integrated system-wide tests. This is hardly no action and would permit an indeterminate missile defense program, especially since, as explained in the draft, “There are currently no final or fixed architectures and set of requirements for the proposed BMDS.” Even if MDA agreed to the “No Action Alternative,” it would not find its actions constrained for the foreseeable future. The MDA needs to develop new alternatives which meet the intent of NEPA.

Most crucially, the “No Action Alternative” strangely links world events, policy objectives with environmental considerations; unprecedented in an environmental document which is supposed to be grounded in the science of risk assessment. The PEIS reads:

> “The decision not to deploy a fully integrated BMDS could result in the inability to respond to a ballistic missile attack on the U.S. or its deployed forces, allies, or friends in a timely and successful manner. Further, this alternative would not meet the purpose of or need for the proposed action or the specific direction of the President and the U.S. Congress.”

Through the MDA’s own volition, the document goes beyond environmental considerations and opens a Pandora’s Box of analyzing the state of American security, the potential for missile attack, and the appropriate policy responses. Therefore, it is now MDA’s responsibility to respond to all public comment on threat and policy, even those challenging the rationale for missile defenses.

Now that the Pandora’s Box is open on policy, the Missile Defense Agency should, for example, make the case that nuclear deterrents no longer suffice, and MDA should substantiate why BMDS is the preferable security strategy over other Alternatives by which America might be kept safe, such as through United Nations IAEA inspections, international controls on missile sales and missile technology, or diplomacy.

If the agency choices to maintain the current “No Action Alterative” – which we do not support – the final PEIS would need to offer a realistic analysis (and timeline) of missile threats against the American homeland, nor fudge the distinction between theater and strategic threats.

Further, the “No Action Alternative” would eliminate systems integration testing, the very testing that would be needed to demonstrate that a layered missile defense system, as ordered by the President, can work. Elsewhere in this PEIS the President's direction is cited as a reason why no further change in the plan is being considered, but in the “No Action Alternative,” the President's direction is clearly negotiable.

Historically, missile defenses have been divided between battlefield-theater defense and strategic defense. All previous administrations kept these two aspects of missile defenses segregated. A fourth alternative could be to develop and integrate theater defenses while postponing defenses to strategic attack.

TESTING AND DEPLOYMENT

In the statement read by Mr. Marty Duke at the Public Hearing held in Sacramento on October 19, 2004, Mr. Duke said that if testing failed to show that the system worked, the system would not go forward. However, as you know, the system is already being deployed even though it has no demonstrated capability to work under realistic conditions. Accordingly, the environmental process described in this

DC_E0395

PEIS is not believable since the statement made by Mr. Duke on October 19 has already been nullified by the Missile Defense Agency.

SPACE-BASED INTERCEPTORS AND SATELLITES

With respect to space-based interceptors, the PEIS is silent about the fact that missile defense would for the first time weaponize space. While space is certainly militarized, it is not yet weaponized, that is, by deploying attack weapons in space, with the consequences of a new arms race in space. The PEIS does not adequately address the environmental impacts of the consequences of placing strike weapons in space. Also, the relationship between NFIRE and space-based missile defenses, alluded to in the PEIS, should be clarified.

The use of radioactive sources on missile defense satellites, either for surveillance, target tracking and target discrimination, or on space-based missile defense interceptors is not discussed.

The PEIS states that space-based interceptors could be placed in geosynchronous orbit: 35,786 kilometers above the Earth’s surface. To actually get a weapon from geosynchronous orbit to low-Earth orbit or even a lower trajectory of a missile within 20 minutes or half hour and do so accurately is physically impossible. Therefore the PEIS has mischaracterized this space weapon. Simply, any weapon placed in geosynchronous orbit could not be an anti-missile weapon. However such a deployment could be an anti-satellite weapon, an ASAT. The agency should then go through the process of trying the field this ASAT weapon on its own merits.

AIR-BORNE LASER

With respect to the Airborne Laser, the PEIS says that, “the ABL is currently the only proposed BMDS element with a weapon using an air platform.” This is not correct. The PEIS should also address another proposed BMDS element using air platforms, namely, interceptors fired from aircraft.

The PEIS does not present the total quantities of specific hazardous chemicals that would be carried aboard an ABL aircraft nor does it describe the total quantities of specific hazardous chemicals that would be stored on the ground at various test and training locations. In addition, the PEIS does not address the environmental impacts should those chemicals be spread over the land from an accident or aircraft crash, or jettisoned at low altitude in an emergency.

AEGIS BMD

Except for the largely historical discussion in Section D.3, the PEIS does not adequately describe AEGIS BMD operations, the large number of missiles involved, nor the locations where testing or training with those ships and missiles will be conducted, nor the environmental impacts of operational deployment with those ships or missiles.

KILL VEHICLE

The environmental impacts of the development, testing, training, and deployment of the proposed new, high-speed, Kinetic Energy Interceptors are not adequately addressed. In particular, the number and size of these large interceptors is not described nor are the types of propellants and chemicals involved.

GROUND-BASED INTERCEPTOR

A third interceptor site is mentioned in the PEIS but it’s location is not stated or described. More

DC_E0395

importantly, the environmental impact of BMDS operations at that third site are not addressed either. MDA officials have said that this third site could hold up to 20 ground-based interceptors and be bigger than the site at Fort Greely, Alaska. The environmental impacts of such as large operation should be addressed.

Thank you. We look forward to a response.

Sincerely,

Jonathan Parfrey

Subject: Comment on draft BMDS PEIS

To whom it may concern,

I would like to raise the issue of the 3rd ground-based interceptor site, something which I believe has been completely overlooked in the draft Ballistic Missile Defense System Programmatic Environmental Impact Statement. There is no hard and fast information in this document which indicates where the 3rd interceptor site may be located. However, news stories this fall claim that the United States has been discussing with the United Kingdom the possibility of basing our interceptors on their territory. Alternatively, there are reports that Poland may be the host of the third site. Be that as it may, the draft PEIS gives no indication of where the third site will be, nor of the extent of its size. Presumably, if this document is to lay the groundwork for the missile defense network in its entirety, at least several of these alternatives would have to be examined.

Subject: Comments on behalf of over 800 members of Oregon Physicians for Social Responsibility
Importance: High

I am very pleased to be able to comment on the Ballistic Missile Defense System Programmatic Environmental Impact Statement (BMDS PEIS) on behalf of over 800 members of Oregon through the Physicians for Social Responsibility. I am delighted that a sense of system and control and oversight required by NEPA can be applied to this program as it does to other aspects of governmental plans.

I think the most important issue is that the BMDS PEIS does not contain a real No Action Alternative. Your No Action alternative which many people think is a good option really only states that the entire plan be implemented as already underway with only the exclusion of the new layered additions. A real No Action alternative, stops the implementation of the nuclear missile defense system.

This was the choice of President Clinton when he decided in September 2000 not to move forward with deployment because of technical uncertainties and unsuccessful flight tests. In 2003 the General Accounting Office in 2 separate reports raised serious questions about the ability to prove the system was functional. A separate non-governmental report by the Union of Concerned Scientists supported that position in 2004. Their report indicates that operational testing has not even started and that test conditions are not close to being realistic. None of the X-band radars that are central to the system are built hence we are exposing ourselves and the world with a system that has no hope of working.

Even if the technology worked perfectly, the systems being deployed are vulnerable to countermeasures that are easier to build than the long-range missile on which they would be placed. The UCS-MIT report *Countermeasures* was instrumental in calling attention to this problem and contributed to President Clinton's 2000 decision not to deploy the system the Bush administration is now fielding.

Therefore, given the potential severe environmental damage from both testing and deployment of this program, a true no action policy is preferable.

Beyond the lack of proven functionality there are other very important environmental reasons to choose a real no action item.

Whereas, there is no true threat of an intercontinental nuclear attack either on the basis of weak positions of our current allies such as China, Russia and that other states who are considering the development of nuclear weapons such as Iran and North Korea don't have the capability without detection;

Whereas, the implementation of NMDS will require us to withdraw in a more substantive way from the AntiBallistic Missile Treaty, which sends a message that the United States scoffs at international treaties that have up until now protected us and provides a very good and important mechanism for inspections;

We must conclude that the option for maintaining and improving on a prevention strategy based

DC_E0402

on international cooperation, inspection and enforcement of international treaties that are agreed to by all parties is the most effective option.

The impact environmentally and socially of the incredible amount of money to be spent has also not been addressed. The Pentagon's missile defense and space budgets together stand at over $23 billion, which does not include highly classified "black budget" spending this year alone. However, this year's allocations represent only a small portion of the Defense Department's anticipated investment on the system. In five years the Bush Administration estimates ballistic missile defenses will cost some $53 billion per annum. The full cost of deploying and maintaining BMDS is estimated to be between $800 billion and $1200 billion over the next 15 years. This represents an incredible amount of money will have been circumvented from true protection of public and environmental health.

In addition, our posturing to continue to build this non-functional system stimulates other countries to strive harder and faster to develop nuclear weapons to protect themselves from the United States whom they perceive as a rogue state, that violated international law by invading Iraq. When other nations devote a larger percentage of their national budget on military and defense then the environmental issues are neglected. These countries will then unleash untold amounts of pollution and plunder their natural resources that are wasted all for the sake of protection from the United States, not the least of which is their own nuclear and toxic environmental exposures to the world's citizenry including the U.S. since nuclear fallout has no boundaries.

Of course it can't be stated enough that this cycle also increases the chances of a nuclear accident.

The costs of this program for the United States while increasing pollution, keeps us from devoting adequate funds from the clean up of former nuclear sites where at Hanford alone still threaten groundwater and the Columbia River.

Direct Environmental Impacts

The BMDS has unacceptable environmental risks.

1) The result of release of hydrogen chloride, aluminum oxide, and hydrochloric acid into the upper atmosphere will consume huge amounts of ozone, resulting in dramatic increases in UV light exposure with epidemics of skin cancer, cataracts and the less studied but know effects on sensitive species such as amphibians and microscopic organisms.

2) Radioactive fallout from intercepted missiles has not been considered in this PEIS. The accepted concept that a missile blown up in the outer reaches of the atmosphere is a the logical conclusion of the BMDS alone should keep us from deploying such a system and rather focus on truly preventative strategies that do not accept any nuclear weapon use by any country.

3) Rocket launches result in incredible amounts of chemical releases. Liquid propellants containing hydrazines, nitrogen tetraoxide, and other compounds are highly toxic to all living species. Ammonium perchlorate used in solid propellants blocks the formation of key thyroid hormones which are critical for growth and development especially in fetuses and children. The PEIS proposes to allow over 30-fold higher levels of perchlorate (200 parts per billion) than that proposed by the State of California (6 parts per billion).

4) The risk of accidental missile launching to civilian or military aircraft is a real concern. The window of opportunity for successful launch is too narrow given its unproven track record, that the target identification is inadequate. This will result in incredible toxins being released as aircraft contain fuel,

DC_E0402

sometimes depleted uranium ballast, among other cargos not to mention the deaths of innocent victims.

5) The fuel needed for space based interceptors or satellites will most likely be nuclear. Solar energy appears too unreliable hence our conclusion that nuclear sources will be used. Nuclear exposure will likely occur then given a 15% failure rate of launch, as evidenced by the recent satellite crash in southern United States with little and inadequate information on the nuclear waste exposure.

6) Space debris from high altitude, mid-course missile intercepts or destruction of satellites will also result and contribute to significant interference to peaceful satellite missions and rain down toxic debris.

Thank you for the opportunity to comment on this very important issue. I would like a receipt of my comments.

Sincerely,

Catherine Thomasson, MD

To: mda.bmds.peis
Subject: Amended statement

To Whom It May Concern,

I've been alerted to the problems of BMDS and am submitting these comments on the PEIS.

My major concerns have no place in the narrow confines of the comment process but I add them at the end anyway because the unintended consequences of many seemingly benign endeavors have come back to haunt humanity.

To directly address the impacts of BMDS, I have these comments:

1. It is too expensive for what we get. The opportunity cost of that money going to BMDS could bankrupt us the way the USSR exhausted itself with its military budget. We would be better off with a more educated population who have decent jobs, and a cleaner environment, which we won't be able to afford.

2. The hydrogen chloride injected into the atmosphere with each launch has incredible potential to neutralize ozone, enlarging the famous hole which now requires Australian school children to be outside only with hats and long-sleeved shirts.

Now for the larger picture. The BMDS PEIS does not include a real "No Action Alternative" of not developing ballistic missile defenses, Like a number of medical treatments, from bleeding people hundreds of years ago to Viox a month ago, the remedy is worse than doing nothing.

As a teenager, I was proud that my father worked for the Arms Control & Disarmament Agency. Besides the huge tax savings that resulted from the test ban treaties, we have no idea of what sort of nuclear catastrophe we avoided.

Much later, when President Reagan brought up his Star Wars notion, the feasibility reports made it clear what a ridiculous idea this was, like trying to stop a bullet with a bullet. Nevertheless, by preying on Americans' fears, Star Wars was moving ahead. Luckily, the collapse of the Soviet Union ended the foolishness.

By building Star Wars, we set a terrible example to other nations that we intend to be invulnerable, and therefore we become a threat to all other nations. They have no reason to trust us not to initiate war.

We now live in a world of terrorist threat. We need to learn that resentment of imperious America fuels more violence than we can ever head off, and that threats to our security will be as low tech as having religious fundamentalists give up their lives to pilot planes into office buildings. Fairness, respect, and cooperation are key in defusing

True, there are other nuclear nations that could launch against us. However, it would be far wiser to give every North Korean, Pakistani and Indian a share of what it would cost to build Star Wars so they can buy land, build houses, start businesses, and educate their children. Peace comes from contented people in prosperous nations.

Americans don't pay much attention to complex technological and scientific issues. But when they find out the monetary and social costs of following the wrong experts' advice, they get very angry.

Citizens rose up to stop above ground atomic bomb testing and supported the test ban treaty. We insisted on the Clean Air and Clean Water Acts. We buy more organic food every year because that is safer to eat and better for the environment.

Why not do the right thing now, instead of trying to clean up the mess later? An ounce of prevention is worth a pound of cure.

Subject: Comments on Proposed BMDS PEIS

11-17 Gould-NMD Comments.doc (...

November 17, 2004

MDA BMDS PEIS
c/o ICF Consulting
9300 Lee Highway
Fairfax, VA 22031

To whom it may concern:

I am submitting the following brief comments regarding the BMDS PEIS. In addition to being an Associate Pathologist at Kaiser Hospital in San Jose for more than 23 years, I am currently Immediate Past President of the national organization Physicians for Social Responsibility (PSR), which comprises approximately 30,000 members. Our organization is committed to the elimination of nuclear and other weapons of mass destruction, the achievement of a sustainable environment, and the reduction of violence and its causes. PSR is the U.S. affiliate of the International Physicians for the Prevention of Nuclear War (IPPNW), recipient of the 1985 Nobel Prize for Peace for its efforts to prevent nuclear war. I have been President of the SF-Bay Area Chapter of PSR since 1989, and I am writing this on behalf of our approximately 2,000 physician and allied health professional membership.

In considering the Environmental Impact of the proposed BMD system, the PEIS should address the full extent of possible environmental impacts on our planet and the proposed surrounding outer space intended field of operations. Concerns include not just potential direct environmental damage, but indirect effects. The latter include the potential for encouraging the continued global proliferation of nuclear weapons with associated environmental effects ranging from development, production, testing, deployment and use. They also include the fiscal impact of projected costs of the BMD system that could otherwise be used to redress the significant health and environmental problems that plague our planet, and that would likely increase with anticipated accelerated global climate change. These problems need major investments in capital that are being squandered on wasteful projects such as the BMD that inherently violate fundamental public and environmental health principles of primary prevention—-in this case concentrating on eliminating the source of the problem being "defended" against: the continued stockpiling and proliferation of nuclear weapons.

Specific comments follow:

1) The BMDS PEIS does not adequately address a number of potential environmental and health hazards that would be associated with various aspects of development and deployment. These include:

a) The planned heightened increase in missile launches would potentially lead to increased exposures to the population from toxic pollutants. These include liquid propellants containing hydrazines, nitrogen tetroxide, and other toxic compounds. In addition, the ammonium perchlorate used in solid propellants blocks the formation of key thyroid hormones which are critical for the growth and development especially in fetuses and children. The PEIS proposes to allow an over 30-fold higher level of perchlorate (200 parts per billion) than those proposed by the State of California (6 parts per billion). The numerous anticipated rocket launches will release chemicals including aluminum oxide,

hydrogen chloride and hydrochloric acid into the upper atmosphere, with the potential for further depleting the diminished ozone layer.

For example, each molecule of hydrogen chloride consumes 100,000 molecules of ozone, resulting in the widening of the ozone hole, thereby dramatically increasing levels of UV light. Elevated levels of UV light cause sunburn, skin cancer, cataracts, and many other forms of UV damage to sensitive species;

b) The potential risks posed by BMD missiles accidentally shooting down civilian and/or friendly military aircraft;

c) The potential impacts of space debris from high altitude, mid-course missile intercepts or destruction of satellites on global populations;

d) The potential environmental impacts of nuclear power sources that would likely be employed for deploying space-based satellites and interceptors;

e) The potential radioactive fallout from intercepted missiles.

2) The proposed BMDS is extremely economically wasteful at a time of constrained domestic budgets that are likely to persist far into the future, given the combination of massive military budgets and tax cuts. As indicated in the aforementioned general comments, the monies proposed for the BMDS could better be spent to redress a variety of compelling national and global health and environmental problems.
In 2004, the U.S. is spending approximately $450 billion on its military – and this does not include the past and present "supplemental" costs of the wars in Iraq and Afghanistan, which are already estimated at an excess of $200 billion. The DoD missile defense and space budgets of over $23 billion do not include highly classified "black budget" items. On top of this, in five years, the present U.S. Administration estimates that ballistic missile defenses will cost approximately $53 billion per year. The full cost of deploying and maintaining BMDS has been estimated to be between $800 billion and $1,00 billion over the next 15 years.

3) The BMDS is being proposed at a time when there are only two potential US adversaries (China and Russia) that have the capacity to deliver a long-range missile that can reach the United States. Currently, China maintains only 18 de-alerted missiles that can reach the US mainland. At present no other nations threaten to deploy attack weapons in space. We believe that US deployment of anti-missiles and space-based weapons will provoke increased hostility towards the U.S., heightening the chances of China and Russia and other nations responding with their own innovations and counter-measures. A good example of this was the announcement by Russian President Putin of a new nuclear missile system in line with previously disclosed plans to develop a new generation of sea- and land-based missiles capable of penetrating ballistic missile defense systems. ("Russia Is Said to Develop New Nuclear Missile," AP, New York Times, November 17, 2004) Hence, instead of affording Americans secure protection from missile attack, the proposed defenses may lead to a situation of greater danger. It is also well-known that the elaborate BMD systems being planned would be ineffective against low-tech attacks by terrorists who have already demonstrated the deadly use of box cutters and smuggled weapons, or who could possibly employ radiological weapons in the future.

4) The BMDS PEIS does not include a real "No Action Alternative". Such an alternative that does not include further development testing or deployment of BMDS weapon systems needs to be considered and included in the PEIS. Such a "No Action Alternative" would include strong support for efforts by the UN and nations around the world to enhance security through strengthening inspection and verification protocols of existing treaties, and by re-commitment to arms control and disarmament approaches that to date have served to limit global Weapons of Mass Destruction (WMD) proliferation. As such, the PEIS needs to consider explicitly whether the BMDS would itself encourage the proliferation of WMD, as well as an arms race in space, with examination of the likely response of other nations to the BMDS. As the BMDS is coupled to continued U.S. nuclear weapons programs, will this lead other nations horizontally proliferate for "deterrence" capabilities?

Please acknowledge that you have received these comments.

Respectfully submitted,

Robert M. Gould

Attention: Public Participation Officer

Dear Sir or Madam,

Please factor an inhalation pathway for exposure to ammonium perchlorate. Please asses for both public and occupational exposure. For toxicity information on this newly discovered pathway please see the following study.

1: Wei Sheng Yan Jiu. 2004 Mar;33(2):208-10. Related Articles, Links

[Study on the injury effect of ammonium perchlorate to lung]

[Article in Chinese]

Yang H, Peng K, Chu Q, Zhao S.

Public Health School, Tongji Medical College, Huazhong University of Science and Technology, Wuhan 430030, China.

OBJECTIVE: To study the injury effect of ammonium perchlorate (AP) to lung and to explore whether AP can cause pulmonary fibrosis. METHODS: To detect the levels of cell counts, TNF-alpha, MDA, HYP and the synthesis of collagen in BALF or rat lung after a certain time when rats were injected AP by intratracheal instillation. RESULTS: AP could bring about acute lung damage and inflammatory reaction. The levels of TNF-alpha of different groups in different time were obviously higher than the normal control group($P < 0.05$). AP could affect the levels of MDA, HYP and the synthesis of collagen. But it had no obviously pathological change of pulmonary fibrosis. CONCLUSION: There were acute injury effect about AP to lung, but this experiment could not make sure whether AP could cause pulmonary fibrosis.

Comments:

November 17, 2004

Dear US Missile Defense Agency (MDA);

Please consider the following comments on the Draft Programmatic Environmental Impact Statement (PEIS) of the Ballistic Missile Defense System (BMDS).

1) Addressing Scoping Comments: I submitted a number of comments, on the scope of the BMDS several of which appear to have not been adequately addressed in the draft BMDS PEIS. These will be addressed in each specific comment. As discussed with Mda officials at the Sacramento public hearing, the MDA should provide more time for additional individuals from the most affected regions, including California and Alaska to comment on the BMDS PEIS.

2) Security, freedom, civil liberties, prosperity, the rule of law and the defense of the US constitution and its environment are very important to me as a citizen of this great country. Environmental sustainability is indelibly tied to our prosperity, and more abstractly to our security and freedom. We all want to be safe form missile attack. However, I am very concerned about the interconnected environmental, security and arms proliferation consequences of the US Missile Defense Agency (MDA) plans to establish a vast land, air, sea, and space- based Ballistic Missile Defense System (BMDS) including interceptor and laser weapon systems, sensors and command and control communication systems. The BMDS presents a number of toxic contamination and exposure risks as well as risks to

DC_E0427

health and safety that must be considered under the National Environmental Policy Act (NEPA). In so many cases the BMDS PEIS under estimates the magnitude or importance of these risks. These underestimates of environmental effects will be discussed under specific comments.

3) The BMDS PEIS does not include a real "No Action Alternative". Such an alternative that does not include further development testing or deployment of these weapon systems needs to be considered and included in the PEIS. The BMDS PEIS has not considered the "No action Alternative" of re-joining the UN and many nations of the world in working to enhance security through treaties and arms control and disarmament approaches, e.g. the approach that has provided us with long-term security to date.

4) The BMDS does not consider the direct, indirect and cumulative effects of the BMDS as required by NEPA, especially in regard the effects of the BMDS on the Arms race, which puts us closer to the disaster of nuclear war. In this regard, the PEIS is completely lacking a non-proliferation analysis. The BMDS tries to sell missile defenses to the public as a way to go beyond nuclear deterrence. Yet the BMDS is a dramatic escalation of a missile defenses that is not relevant for defending from terrorists who are much more likely to smuggle WMD. Securing loose nuclear materials is a much more effective strategy for preventing such terrorist nuclear threats.
The BMDS PEIS ignores the fact that the US posses extensive offensive nuclear and conventional weapon systems and that the proposed BMDS will operate along side these offensive weapon systems. The BMDS PEIS ignores the fact that the U.S. has a preemptive nuclear and conventional first-strike warfare policy and has exercised this policy in preemptively / preventatively invading other countries that have not attacked the U.S. including Iraq. Pronouncements of US preemptive offensive nuclear and conventional first strike policy as articulated in the 2002 Nuclear Posture Review; the 2002 Defense Guidance Policy; many statements of Bush, Cheney, Rumsfeld, and Wolfowitz, as well as the unprovoked 2003 invasion of Iraq, have together furthered international fears of the prospect of unprovoked unilateral attacks by the US. Building a massive land, sea, air and spaced-based BMDS is very likely to further invoke international fears that it will be used in conjunction with US offensive first strike and command and control communication systems to attack and/or dominate other countries.

The BMDS PEIS ignores the reasonable forseeability that it forces other nations to proliferate and/or smuggle WMD so that they can re-establish deterrence. Indeed, Russia and China have already started to proliferate and develop counter measures in response to the impending development of the U.S. BMDS (Evans 2004). Previously non-nuclear nations such as North Korea have stated that they also proliferated in order to establish a deterrent. In short, many nations are concerned that a US BMDS will eliminate their ability to deter attack, and assure the ability of U.S. forces to intervene anywhere in the world with offensive weapons systems. Such fear and insecurity has a reasonable forseeability of driving WMD proliferation and thereby decreasing rather than increase our security for years to come. Such WMD proliferation and the treat of nuclear war will have major environmental consequences. Thus, the BMDS needs a non-proliferation analysis which considers the direct, indirect and cumulative effects of the BMDS as well as other entities.

In essence, the combined direct, indirect and cumulative effects of the proposed BMDS in conjunction with US offensive weapon systems and US preemptive first strike military policy is very likely to invoke fear of US actions and intentions. Furthermore, a BMDS would be much more likely to be effective in intercepting ICBMs of another nation, if the BMDS were to be used following a preemptive nuclear first strike. Since the nation that strikes second loses for sure, the BMDS destabilizes the policy of nuclear deterrence that has helped to keep the peace for over 50 years. There is more than a reasonable foreseeability that the resulting paranoia will cause a major arms race, and send us into confrontations and wars of great scale. Such wars seriously threaten all we as a people hold dear; health, safety, and our environment.
The threat of the BMDS leading to a more aggressive nuclear policy and nuclear war can be seen in the

historic article "Victory is Possible" by Colin S. Gray and Keith Payne, Foreign Policy Summer 1980, pp. 14-27. These authors state: "If American nuclear power is to support U.S. foreign policy objectives, the United States must possess the ability to wage nuclear war rationallyŠ.
"ŠThe United States should plan to defeat the Soviet state and to do so at a cost that would not prohibit U.S. recoveryŠ.
Washington should identify war aims that in the last resort would contemplate the destruction of Soviet political authority and the emergence of a postwar world order compatible with Western valuesŠ.
Once the defeat of the Soviet state is established as a war aim, defense professionals should attempt to identify an optimum targeting plan for the accomplishment of that goal. For example, Soviet political control of its territory in Central Asia and in the Far East could be weakened by discriminate nuclear targeting. The same applies to Transcaucasia and Eastern EuropeŠ.
Strategists cannot offer painless conflicts or guarantee that their preferred posture and doctrine promise a greatly superior deterrence posture to current American schemes. But, they can claim that an intelligent U.S. offensive strategy, wedded to homeland defenses, should reduce U.S. casualties to approximately 20 million, which should render U.S. strategic threats more credible. Š
A combination of counterforce offensive targeting, civil defense, and ballistic missile and air defense should hold U.S. casualties down to a level compatible with national survival and recovery. The actual number would depend on several factors, some of which the United States could control (the level of U.S. homeland defenses); some of which it could influence (the weight and character of the Soviet attack); and some of which might evade anybody's ability to control or influence (for example, the weather). Š
No matter how grave the Soviet offense, a U.S. president cannot credibly threaten and should not launch a strategic nuclear strike if expected U.S. casualties are likely to involve 100 million or more American citizens." Š (**Victory is Possible** by Colin S. Gray and Keith Payne *Foreign Policy*, Summer 1980, pp. 14-27).
Note that these authors also helped to write the 2002 US Nuclear Posture review, which further solidifies the US preemptive nuclear first strike policy. Gray and Payne make it clear that BMD is essential for a more aggressive US nuclear first strike policy. Thus, there is a reasonable foreseeability that the BMDS in conjunction with US offensive nuclear forces will increase the probability of a massive nuclear war. Thus, the BMDS needs to include a detailed analysis of the environmental effects of "limited" and "all out" nuclear war, including: medical radiological, blast, burn, fallout, disease, and cancer effects to health and safety; effects on nuclear winter, as well as effects on atmosphere, global supplies of fresh water, global food supplies, and nuclear power plants and power systems. The prospect of the BMDS leading to more aggressive US policies that result in a massive nuclear war also needs to be considered in regard to a true no action alternative.
In short, since there is a reasonable forseeability that the BMDS in conjunction with US and Allied nuclear weapon systems and current US nuclear weapons policy as defined in the 2002 Nuclear policy review will destabilize the nuclear arms race and lead to nuclear war, the environmental consequences of nuclear war need to be considered I detail in the BMDS PEIS. (Ambio Volume XI number 2-3, 1982, Nuclear War: The Aftermath. Entire journal dedicated to the effects of nuclear war, including effects on heath and safety, Air, water resources, agriculture, biological resources, and nuclear winter.)

This requested in my scoping comments was ignored. e.g. Scoping comment "#18) The MDA needs to consider whether the BMDS in conjunction with offensive first strike weapon systems and first strike policy increase the probably of a major nuclear war or other disturbance that could result in nuclear Winter, with the associated loss of species"

5) **The BMDS PEIS did not adequately consider impacts of Hazardous waste and materials and on Health and safety, Water Resources and Biological resources of environmental contamination from toxic and hazardous components of rocket fuels and explosives.**
The BMDS PEIS markedly under reports the emissions of representative interceptors. Exhibit 4-11

reports the emission of (90+58+52+22+17+6+6)=251 pounds for a representative interceptor. However, ground based interceptors are much larger (approximately 54 feet long 3 stage solid propellant rockets (such as the Minuteman III) weighting 22.5 to 25 tons and containing approximately 30,000 to 45,000 pounds of solid propellant. Thus the MDA underestimates the emissions from such interceptor rockets by factor of greater than 100. This is totally unacceptable. This underestimate of BMDS pollutants is apparently repeated in Exhibits 4-13, 4-14 and 4-15. Thus the MDA needs to revaluate the environmental effects of these pollutants. Also the MDA should define what are the emissions from the missiles used to launch spaced based interceptors, and sensors.

6) Not only does the BMDS PEIS under represent the total amount of emissions, from the estimated 515 BMDS rocket launches over the next several years, it also discounts that this program will be injecting large quantities of chemicals including aluminum oxide, hydrogen chloride and hydrochloric acid into the upper atmosphere, stratosphere, etc. Most concerning is the injection of hydrogen chloride into the upper atmosphere where the breakdown of each hydrogen chloride molecule to chloride ion catalyzed the breakdown of 100,000 ozone molecules, thereby depleting ozone, and decreasing the blocking of UV rays. This depletion of ozone will increase risk of cataracts and skin cancer. Thus, the BMDS will have a much greater effect on ozone depletion and skin cancer than HCl released at sea level.

7) Liquid propellants containing hydrazines, nitrogen tetroxide, and other compounds are highly toxic. At very low concentrations, hydrazines irreversibly cross link to aldehyde groups on proteins at slightly acidic pH and can cause cancer. One of the most concerning pollutants from the firing of rocket engines is HCl, which combines with atmospheric water to produce acid rain. The PEIS did not address potential for interactions between HCl and hydrazines commonly used in rocket engines such as monomethylhydrazine (MMH) and Unsymmetric dimethylhydrazine (UDMH). Specifically does the toxicity of hydrazine increase under acidic conditions found in acidic rocket exhaust?

8) Ammonium perchlorate is one of the main components of rocket fuel, typically constituting 60% to 75% of missile propellant and about 70% of space shuttle rocket motors. Since the fuel and perchlorate goes flat, the fuel/perchlorate has to be replaced every few years or it will fail to function properly, thereby increasing the amount of perchlorate waste and exposure problems.
Ammonium Perchlorate is well characterized as a thyroid hormone disruptor.
http://www.ewg.org/reports/rocketscience/chap3.html . **At high enough concentrations, perchlorate can affect thyroid gland functions, where it blocks iodide uptake necessary for the synthesis of thyroid hormones (Urbansky 2002). Perchlorate can cause hypothyroidism, and thyroid cancer.** The environmental levels of perchlorate have been show to inhibit development in frogs (Goleman et al. 2002). California has extensive perchlorate contamination problems with the drinking water sources of at least 7 million Californians and millions of other Americans are contaminated with perchlorate. A federal **safe daily perchlorate exposure has not yet been set by the EPA, and its expected release in 2002 has been delayed. It has been delayed since the DoD objected to EPA studies suggested a standard of 1 ppb.** Senator Barbara Boxer has introduced legislation to require the EPA to establish a standard for perchlorate contamination by July 1, 2004. While most contaminated samples are in the 4 to 20 ppb levels, surveys of California water sources show several sites with perchlorate levels from 4 to 820 ppb.
http://www.ewg.org/reports/rocketwater/table1.php
Ammonium perchlorate used in solid propellants blocks the formation of key thyroid hormones which are critical for growth and development especially in fetuses and children. The PEIS proposes to allow over 30-fold higher levels of perchlorate (200 parts per billion) than that proposed by the State of California (6 parts per billion). As pointed out in the comments of Lenny Siegel: The reason that there is no federal drinking water standard for perchlorate is that the Defense Department objected to EPA studies that suggested a standard of one part per billion (ppb). Meanwhile, regulatory agencies are using levels far below the 200 ppb asserted in the PEIS. On the way to establishing its own legal standard,

California has adopted a Public Health Goal of 6 ppb (Frequently Asked Questions (FAQs) About the Public Health Goal for Perchlorate," California Office of Environmental Health Hazard Assessment (OEHHA), March 11, 2004. http://www.oehha.ca.gov/public_info/facts/perchloratefacts.html). Even these levels of perchlorate may be detrimental to fetuses and infants. The human study considered in setting the California public health goal did not evaluate pregnant women, fetuses or infants (Greer et al. 2002). The study of Greer et al 2002, only used a 14-day exposure to perchlorate, which is insufficient to deplete thyroid colloid which acts as a storage form of thyroid hormones. Thus this study is insufficient to estimate the effect of long-term perchlorate exposure on iodine uptake or thyroid hormone levels. Since the effect of long term perchlorate exposure on reducing thyroid hormone levels, especially in the fetus and in infants has not been considered, the MDA needs to evaluate these effects on these sensitive groups as required by federal law. In May, 2004, Massachusetts identified a reference dose for perchlorate that would correspond to a 1 ppb drinking water exposure limit. Also note that perchlorate is found in milk and in several plant species, including lettuce, where high levels have been reported. Thus multiple sources of perchlorate exposure need to be considered.

9) To ensure maximum environmental protection and reduce known, widespread human health risks from the use and disposal of rocket propellants, the BMDS PEIS should compare the proposed alternatives against a real No Action Alternative. At a minimum the BMDS PEIS should:
A. Acknowledge and address emerging regulatory standards for perchlorate exposure.
B. Consider the effects of perchlorate on susceptible subpopulations, including fetuses, and children. The MDA also needs to consider the effects of perchlorate exposure on even more sensitive congenitally hypothyroid populations, so that these individuals are not detrimentally affected by perchlorate from BMDS missile launches.
C. Since water supplies in several regions of central and southern California are already at, exceeding and in some cases markedly exceeding the emerging regulatory standards for perchlorate, the MDA should acknowledge and address the perchlorate problem so as to protect the public.

10**) The BMDS PEIS did not address my scoping comments that the** PEIS should address whether the BMDS testing endangers Health and Safety by missing its target or targeting the incorrect vehicle. The BMDS as described on the MDA web site is a risk to public safety as shown by the Patriot 3 (PAC-3) shooting down US and Allied British military planes during the 2003 US / British invasion of Iraq. According to a report in USA Today April 15, 2003, titled "Patriot Missile: Friend Or Foe To Allied Troops?" By Andrea Stone, It is seems that the Patriot has difficulty determining "friend from foe". In the first incident, on March 22, a Patriot missile downed a British Tornado GR4 fighter-bomber near the Iraq-Kuwait border, killing the two-man British crew. A U.S. F-16 fighter jet had to fire on a Patriot missile radar in Iraqi after the radar "locked on" to the jet. A Patriot-3 battery was also suspected in the downing of a U.S. Navy F/A-18 Hornet near Karbala on April 2, killing the pilot. Since several other Patriot friendly fire malfunctions are known, the MDA needs to consider how many civilians will be killed by the patriot BMDS.
Furthermore, the Aegis Cruiser system is a threat to commercial aircraft, as shown by the USS Vincennes mistakenly shooting down the Iranian Airbus commercial airliner flight 655 on July 3, 1988, killing all 290 civilians aboard http://www.geocities.com/CapitolHill/5260/vince.html . Over 100 witnesses reported seeing an upward arching flash of light immediately before TWA flight 800 exploded off of New York. However, government investigators refused to consider whether a missile launched from an unannounced ongoing naval exercise could have been the cause of the crash. The point is that the activation of BMDS risks accidentally shooting down civilian airliners, which was not even considered in the BMDS. While the BMDS states that warning will be provided to enable time to clear the airspace, it is highly doubtful that such time would be allowed in a perceived emergency. The BMDS PEIS needs to address these threats.

Both the PAC-3 and Aegis Cruisers are included as components of the proposed BMDS Since the PAC-

3 is a relatively short range system and is not designed for intercepting ICBMs, how many PAC-3 batteries will have to be deployed to offer full protection for the American and allied cities and military bases. Are these within range of any civilian aircraft? How will they discriminate attacking aircraft from commercial and civilian aircraft? The MDA needs to consider how many civilians and US/allied military personnel will be accidentally killed by the BMDS.

11) The PEIS provides conflicting information on the effects of the ABL on health and safety. The PEIS does not quantitatively assess the risk of the Airborne Weapons Laser (in a Boeing 747) blinding pilots and/or other civilians, stating mainly that humans and others would be exposed to the laser beam, mainly as reflected light for less than 0.01 seconds. However the PEIS provides no data on the wattage or power of these lasers in the PEIS making it impossible to assess the dangers of such laser exposure, especially to the eyes.
On Oct. 30, 1995, a Southwest Airlines' pilot in control of a flight departing McCarran International Airport in Las Vegas was temporarily blinded by a laser light. According to news reports, the incident was serious enough to force the plane's captain to take control until the pilot regained his sight. "Had it hit me and the other pilot simultaneously, I shudder to think what would have happened," the pilot told reporters. (http://www.fda.gov/fdac/departs/496_irs.html). Had the pilot been exposed to a high energy laser (HEL) as used in the BMDS the results could be much more debilitating, endangering the health and safety of numerous passengers.

The BMDS PEIS (page 4-32) cites that exposure to a reflected laser beam while in the air operating environment would be very short, < 0.01 seconds that and would not impact the health and safety (US Air Force 1997A). But no estimates are provided for the actual danger zone for the HEL to detrimentally affect health and safety, e.g. causing skin and especially retinal damage. The Draft Supplemental Environmental Impact Statement for the Airborne Laser Program (2002) (page 99) cites the power of the HEL as about 107 watts per square centimeter. Ten million watts per square centimeter will burn retinas and eyeballs very quickly. While the PEIS states that medium energy lasers such as the SHEL if focused at point 12 km away, would be hazardous to the human eye 2 km before to 2 km past the focus point. Where as the other lasers and especially the HEL would be hazardous immediately after leaving the turret of the ABL. While the PEIS states that the BILL and TILL no hazard distance would extend > 10 km beyond the target, and the HEL hazard distance would extend even beyond these distances. But the BILL, TILL and I presume the HEL hazard distances are apparently classified. How can the public comment on the effects of the BILL TILL and especially the HEL on health and safety if the of distance at which these lasers cause eye damage is not available? The public and the MDA / Air force need to make this information available to better ensure the heath and safety of the public.

The PEIS focuses on the testing of these lasers, but fails to reveal whether once deployed, the ABL or any other BMDS weapons lasers will ever be directed toward aircraft including airliners, or individuals on the surface of the earth, e.g. on land or at sea. If so, the MDA needs to address the effects of HEL and other weapons lasers on endangering health and safety, especially skin and eye damage.

12) The MDA PEIS needs to consider whether boost phase BMDS interceptors could be launched erroneously, causing another country to believe it was under attack, and thereby triggering a nuclear war. The American Physical Society examined the issue of boost phase intercept, and determined that the interceptor has to be very close to the ICBM, be launched within about 15-60 seconds from the time the ICBM was launched, and have much greater accelerations than the ICBM http://www.physicstoday.org/vol-57/iss-1/p30.html (Kleppner et al. 2004). The problem of boost Phase intercept is greater for solid rockets with high accelerations than for slower accelerating liquid rockets. The further problem is that ship based interceptors are not big enough and do not have sufficient accelerations to make a boost phase intercept even from a small country like North Korea and if it did intercept it is likely the warhead would not be destroyed by a kinetic hit-to-kill interceptor and would

continue on to near its intended destination. Finally, they point out that a boost phase launch intercept of a ICBM from North Korea would likely occur over northern China, further risking causing China to think it was under attack by the US which could cause a nuclear war (Kleppner et al. 2004). The BMDS needs to consider the realities of the limitations of any BMDS relative to a real no-action alternative of working toward disarmament through arms control treaties.

13) Space debris from high altitude, mid-course missile intercepts or destruction of satellites. The PEIS does mention that even tiny particles of space debris traveling at extremely high speeds in orbit can destroy space suits, rockets and satellites. While the PEIS correctly points out that debris from low orbital intercepts will decelerate once it hits the atmosphere, and thereby de-orbit. However the PEIS fails to consider the space debris from high altitude intercepts which risk producing space debris that could make space unusable for many years. While the PEIS considers testing the BMDS on "targets of opportunity", no mention is made of space debris resulting if other nations target US BMDS satellites or components in high orbit as "targets of opportunity". This must be considered since the resulting space debris could destroy objects in space, making space unusable as well as violating the 1967 space treaty.

14) The environmental consequences of many rocket launches needed to deploy and maintain space-based interceptors has not been adequately considered, nor has the environmental consequences of their fuel. Will space-based satellites/interceptors use nuclear power sources? Will any BMDS interceptors ever use nuclear warheads? While nuclear tipped-interceptors are not mentioned in the PEIS, per se. In Section 2.2.1.1 the PEIS does mention the possibly of destroying a missile by using interceptors with directed blast fragmentation kill vehicles. However the PEIS, fails to reveal the nature of the blast fragmentation device, which is needed for evaluation of its environmental effects. Instead the MDA PEIS states that "the interceptors will be discussed and analyzed for environmental impacts at the booster and kill vehicle level. This will allow the MDA the flexibility to configure new interceptors based on boosters and kill vehicles analyzed in this document to address new or emerging threats." This does not allow a satisfactory evaluation of the hazards of the BMDS components. What blast fragmentation devices will be used? The PEIS needs to include the details of chemical and toxicant use and exposure.

15) Radioactive and/or biological weapons fallout from intercepted missiles has not been considered in the PEIS. If a kinetic hit to kill interceptor knocks out an ICBM in the mid phase or terminal phase, the nuclear warhead or its fragments are going to produce a tremendous amount of radioactive contamination where ever they land. Such radioactive fallout will clearly have major, highly deleterious effects on adults, children, and especially on developing embryos, and fetuses. While such an interception is very likely to be highly preferable to damage resulting from an air or ground burst over a city, the resulting radioactive contamination needs to be considered. The effects of war are normally excluded from analysis by the National Environmental Policy Act (NEPA). However, the proposed BMDS action is very likely to provoke a worldwide WMD arms race, and force other nations to prepare to launch a massive retaliation against the US should war ensue. Thus, these effects need to be considered relative to a real no action alternative. Since the proposed BMDS is very likely to cause a massive arms race, the environmental consequences of a resulting War involving nuclear or other WMD should not be ignored. The PEIS needs to consider the environmental effects of fallout from intercepted WMD as well as the effects of WMD the BMDS fails to intercept. Thus PIES needs to consider these hazardous waste and materials issues. Appropriate references include "The Effects of Nuclear Weapons, Compiled and Edited by Samuel Glasstone and Philip Dolan, third Ed. DOD, DOE. 1977.

The American Physical society also identified the issue that boost phase intercept has a high probability of munitions carryover. A successful boost phase intercept is unlikely to disable ICBM's warheads or munitions. They will be deflected only slightly, if at all, and will continue on ballistic trajectories (Kleppner et al. 2004).

16) Will any interceptors use nuclear warheads? The PEIS does not address the inability of mid-course or terminal kinetic interceptors to stop a "threat cloud" once a attack missile has MIRVed, or released many decoys or countermeasures (Richard L. Garwin. Holes in the Missile Shield. Scientific American, November 2004, page 70-79). The MDA may be temped to intercept such a threat by using large nuclear tipped interceptors. The potential use of nuclear tipped interceptors was discussed by high ranking US DOD officials in 2002 http://www.washingtonpost.com/ac2/wp-dyn/A28866-2002Apr10?language=printer. If such nuclear tipped interceptors were deployed, the environmental risks would be much greater. If so, the environmental consequences of the nuclear fallout and electromagnetic pulses from such high altitude nuclear detonations must be considered in detail. This would include analysis of risks to health and safety, contamination of water, land, soils, EMP effects on civilian and medical electrical and computer systems and infrastructure. The MDA should also consider the effects of radioactive fallout on health and safety, biological resources, and contamination of land and water resources.
Furthermore, given the historic 15% missile launch failure rate, the radioactive fallout from accidents with nuclear tipped interceptors must be considered in detail. The public should have full opportunity to consider and comment on the use of such nuclear tipped interceptors in this PEIS. The point is that the blast fragmentation devices need to be described in detail to enable adequate evaluation of its environmental effects.

17) Also note that the technology and environmental effects of "advanced systems" remain to be defined. How can the environment effects of an undefined "advanced system" be evaluated in this PEIS? A full environmental analysis is needed for each component of the PEIS to be added. If any component of the BMDS will ever use nuclear warheads in any interceptors the MDA needs to thoroughly consider the environmental effects, as discussed above.

18) Will any MDA interceptors or Lasers use anti-matter weapons? A US Air Force anti-mater weapons research programs has recently been described in the SF Chronicle http://sfgate.com/cgi-bin/article.cgi?file=/c/a/2004/10/04/MNGM393GPK1.DTL. IF the BMDS will use antimatter weapons or energy sources, the environmental effects including the health and safety risks, and chemical exposure risks need to be described in detail.

19) **The BMDS PEIS needs to consider direct, indirect and cumulative effects of the proposed project in conjunction with other federal offensive military weapons systems and policies were not addressed**, but need to be addressed. The National Environmental Policy Act (NEPA) (http://ceq.eh.doe.gov/nepa/regs/nepa/nepaeqia.htm) and especially **The Regulations for Implementing NEPA** (http://ceq.eh.doe.gov/nepa/regs/ceq/toc_ceq.htm), state that both the direct and indirect effects of the proposed project as well as the Cumulative impact of the project should be considered. Sec. 1508.7 States that the "Cumulative impact" is the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time.
In the context of this global ballistic missile defense system, the cumulative impact of reasonably foreseeable future actions of the US as well as other nations, agencies and persons need to be considered. Yet the reasonable foreseeable actions of other nations and individuals responding to the BMDS by proliferating WMD was not considered by the MDA in this PEIS.
As stated in Sec. 1508.8 "Effects" include:(a) Direct effects, which are caused by the action and occur at the same time and place and (b) Indirect effects, which are caused by the action and are later in time or farther removed in distance, but are still reasonably foreseeable. Effects and impacts as used in these regulations are synonymous. Effects includes ecological (such as the effects on natural resources and on

the components, structures, and functioning of affected ecosystems), aesthetic, historic, cultural, economic, social, or health, whether direct, indirect, or cumulative. Effects may also include those resulting from actions which may have both beneficial and detrimental effects, even if on balance the agency believes that the effect will be beneficial.
Thus, by law the MDA also needs to consider the Direct, Indirect and Cumulative impacts on the environment of the proposed BMDS along with other US offensive weapons systems and stated & demonstrated US preemptive first-strike policy.

The following points are points that need to be considered in the no action alternative.
20) The PEIS needs to consider whether the BMDS will result in Proliferation of Weapons of Mass Destruction (WMD) and an arms race in space. The response of other nations to the BMDS has not been considered. Specifically, the BMDS is coupled to other offensive weapons programs and will force other nations to proliferate and/or smuggle WMD so that they can re-establish deterrence. Relatively inexpensive countermeasures to BMD will likely thwart the goals of BMD. Such proliferation coupled with increased international tension will decrease rather than increase our security and lock us in to an expensive and destabilizing arms race and will have devastating long-term environmental consequences.

21) Alternative 3: Not developing, or building the BMDS or any of its components and instead renegotating an expanded and verifiable ABM / BMDS treaty: The ABM treaty helped to stabilize and de-escalate the nuclear arms race for all of its 29 years of existence. No country dared attack the US with nuclear missiles, in part because the U.S. would know exactly where the missile came from and have the clear ability to retaliate and bomb them into obivilion. That is certainly still the case. This option would preserve deterrence and peace. Yet it would enable the nuclear nations to abide by the NPT and reduce the overall level of nuclear weapons, in exchange for non-nuclear nations not developing nuclear weapons.

22) Alternative 4: Preserving Space for non-military purposes. The MDA should consider the alternative of not militarizing space. The planned US militarization and domination of space as described in the US Space Command Vision for 2020 (http://www.fas.org/spp/military/docops/usspac/lrp/ch02.htm) and as described in the 2002 US defense guidance policy and elsewhere, will certainly create and intensify conflicts over the control of space for years to come. These US policy documents talk about "Full Spectrum Domination", "negating" or "destroying" the enemy's satellites and use of space. As US citizens we would like for the US to protect space from militarization, but do we want the US to dominate space, and to start a series of space wars? Think about how you would feel if you lived in another nation and some one destroyed your satellites. Would such actions be considered an act of war?
Additionally how does the BMDS PEIS affect US compliance with the Outer Space Treaty?

23) Alternative 5: Deployment of a much more limited land and or Sea based theatre BMD that would offer protection from attack by short or intermediate range missiles. For example, rather than develop the extensive land, Sea, air and space based system, the US and its allies could instead deploy a currently available Aegis missile cruiser(s) off of North Korea. Such a small, affordable, alternative system would immediately meet the needs of defending Japan against missiles that might be launched by North Korea without invoking fears that it would be used to enable invasions and/or domination of the world and thereby starting a massive global arms race.

24) NONPROLIFERATION ANALYSIS COMMENT
Based on my expertise in the area of genetics, physiology, toxicology and nuclear weapons control/non-proliferation, it is a **reasonable foreseeability** and in my opinion a very high probability that the proposed BMDS creates a significant risk of nuclear and biological weapons proliferation. This

proliferation risk goes hand in hand with a greater security risk, and both increase the potential harm to the environment and the public.

As pointed out by Nicole C. Evans, National missile defenses may undermine strategic stability by threatening the ability of other countries to retaliate, which is the core of their deterrence. Theater missile defenses do not pose this danger (Evans 2004). Evans goes on to describe Russian and Chinese concerns to National Missile Defense (NMD) and especially Global Missile Defense (GMD) as described in the BMDS PEIS. She also describes how Russia and China have already started to proliferate in response to the US renigging on the ABM treaty and preparing to deploy GMD, e.g. the BMDS.

Evans points out that; "Russia and China share two key concerns about American missile defense plans: that their nuclear deterrent is threatened and that American missile defense plans will destabilize arms control. Š
Both Russia and China have responded actively to the American abandonment of the ABM Treaty by developing asymmetrical measures to neutralize any potential threat. By withdrawing from START II, Russia was able to continue deploying multiple independently targetable reentry vehicles (MIRVs) on intercontinental ballistic missiles (ICBMs). Putin announced in October 2003 that Moscow intends to place on combat duty dozens of MIRVed SS-19s, and Russia has also extended the service life of its SS-18 heavy ICBMs. Russia has begun building the fourth-generation *Borey* class of submarines, is MIRVing its silo-based Topol-M, and is finishing testing the mobile version of the Topol-M." In February 2004 Russia also "successfully tested a new hypersonic "Crazy Ivan" warhead that follows a nonclassical scenario, changing flight altitude and course repeatedly, making it nearly impossible to track and target." Evans also points out that "Russia has also upgraded the A-135 strategic single-site ABM system covering Moscow, the only such system currently in operation. In 2002, Russia began working in earnest on TMD and is currently developing several advanced missile interceptors (Evans 2004).

Evans points out that "Both Russia and China appear unconvinced by American assurances that global missile defense is not directed against them, despite echoing American rhetoric about the need to defend against the terrorist threat. Senior Russian military and foreign affairs officials have argued that while the United States proclaims its partnership with Russia, its actions show anything but that. ŠRussian concerns are further aggravated by America's stated intention not to cut its nuclear arsenal to levels designated by the Moscow Treaty of May 2002--instead moving the missiles as well as the warheads into storage as a hedge against an uncertain future." (Evans 2004).

Evans then goes on to describe how China is responding to the US BMDS threat and "is moving toward a more diversified, invulnerable, and combat-ready operational nuclear triad." "Second, Russia and China are very concerned that American missile defense plans will destabilize existing arms control regimes and forestall future agreements."
Russia, China, and other states express deep concern about the weaponization of space. In 2003, Russia and China proposed an agreement for the non-weaponization of space, and negotiations continue at the Conference on Disarmament in Geneva. Both Moscow and Beijing maintain that nonproliferation measures and policing regimes are a better way of dealing with weapons of mass destruction than attempts to develop missile shields" (Evans 2004).
Evans Concludes "The real danger lies in the potential of GMD to disrupt delicate regional balances and to encourage the further development and deployment of nuclear weapons. The United States, China, and Russia have all stepped up their offensive weapons programs since the dissolution of the ABM Treaty. The danger has been succinctly summarized by Mohamed El Baradei, head of the International Atomic Energy Agency: "If we don't stop using double standards, we shall be piled high with an even greater number of nuclear weapons." That would create the exact opposite of the professed objective of

DC_E0427

global missile defense: security for all who want it" (Evans 2004). This article and several others by Arms Control experts show evidence that the BMDS is causing and will continue to cause WMD proliferation rather than preventing it. **Thus, a non-proliferation analysis is needed for the BMDS PEIS particularly in regard to a genuine no action alternative.**

The BMDS PEIS (page 2-68) provided a justification based on politics rather than on analysis of environmental policy as the rationale for not considering a real "No Action Alternative", namely the canceling of Ballistic Missile Defense Capabilities (and re-engaging in treaty - based arms reductions). On page 2-68 the PEIS states " As suggested to the MDA during the scoping process, one alternative would involve canceling the development of all ballistic missile defense capability development and testing. Such an alternative would rely on diplomacy and military measures to deter missile threats against the U.S. However, this proposed alternative would eliminate the capability to defend the U.S., it's deployed forces, allies or assets for a ballistic missile attack should diplomacy of other deterrents fail. This alternative does not meet the purpose of or need for the proposed action as described in Sections 1.3 and 1.4, respectively; does not meet the direction of the President and the U.S. congress; and therefore will not be analyzed further."

A mainly political justification was also given on BMDS PEIS pages 1-14 for not considering scoping comments showing "concern that the BMDS would create an arms race, especially in space" Š comments showing "opposition to the development of nuclear weapons and concern that missile defense could be a first strike capability for U.S. worldwide military domination". Specifically, the MDA PEIS stated the rationale for excluding these comments is that "Public comments concerning DoD policy, budget and program issues are outside the scope of the Draft BMDS PEIS".

These political justifications used by the MDA are insufficient for excluding these and related issues of non-proliferation from analysis in the BMDS PEIS. A non-proliferation analysis is needed for the BMDS. We all want to be safe from missile attack. The non-proliferation analysis is needed to determine if the BMDS is likely to ultimately increase our security, and maintaining environmental quality or result in an out of control arms race that decreases our security and wreaks wide spread environmental destruction.

Because of the reasonable foreseeability of increased potential for environmental harm due to proliferation and security risks, I strongly recommend that the MDA prepare a detailed Nonproliferation Impact Review for the BMDS PEIS including a Nonproliferation Impact Review EIS for each BMD component and for each BMD site or location. These reviews will determine the scope and need for a MDA high-level program and the alternative that would cause the least environmental harm. If the BMDS is the best alternative for such a program, these review processes will thoroughly assess the potential proliferation, security and environmental harms and ways to mitigate those potential harms. This will mean that proactive plans to protect the environment, public safety and national security will be developed in advance rather than in response to a problem, accident or crisis.

DOE Programmatic EIS Precedent

The DOE has set an important precedent by conducting a Programmatic EIS, including a Nonproliferation Impact Review (NIR), for its Civilian Nuclear Energy Research and Development and Isotope Production Missions in the United States, including the Role of the Fast Flux Test Facility in December 2000 and for its Stockpile Stewardship and Management in September 1996. Furthermore, Nonproliferation Analyses were conducted in the following DOE EIS or Site-Wide EIS review documents:

· Final Programmatic Environmental Impact Statement for Tritium Supply and Recycling (October 1995); Section 1.5.6 Proposed Nuclear Weapons Nonproliferation Policy Concerning Foreign Research Reactor Spent Nuclear Fuel, Page 1-10.

DC_E0427

· Final Environmental Impact Statement on Management of Certain Plutonium Residues and Scrub Alloy Stored at the Rocky Flats Environmental Technology Site(August 1998);

·Final Environmental Impact Statement for the Production of Tritium in a Commercial Light Water Reactor (March 1999).): 1.3.5
Nonproliferation, Page 1-9 and 1-10.

Final Site-Wide Environmental Impact Statement for the Y-12 National Security _ _Complex_ (September 2001): Section 2.2.3 Nonproliferation and National Security, Page 2-7.

Following this precedent, the MDA BMDS, in my opinion, necessitates an equally comprehensive review. Such a Nonproliferation Review Should Include Public Hearing, Scoping and Comment.

25) I highly recommend that the Nonproliferation Impact Review be conducted like the NEPA process that includes public participation in the scoping phase and a draft document circulated for public comment. This open process is critical because intent really is the biggest differentiating factor between defensive and offensive military research. The participation of individual citizens who live near the proposed facility and have personal concerns such as health and property values, as well as representatives from professional and nonprofit groups who specialize in public health, emergency response, sewage treatment, landfills, water, environment, toxicology, science, medicine and arms control may identify unforseen problems, more cost-effective solutions and new ways to open up the process while maintaining necessary security. This scrutiny and public debate can only improve the quality of the decision-making process and will likely result in more confidence in the final decision on the part of those most directly impacted.

26) Which government and university institutions in the State of California will be conducting research to support the BMDS research and development and, if so, please describe their roles, responsibilities and the specific projects they will be involved in? Specifically, will Lawrence Livermore National Laboratory, Lawrence Berkeley National Laboratory, Sandia National Laboratory -- Livermore, or the University of California at Berkeley, Davis or Los Angeles be conducting research or development on the BMD for the MDA or DoD and, if so, what specifically will each that is involved be doing? This is important for people in these areas to know in order to understand, consider and evaluate the possible environmental, health, and safety impacts on their communities.

Thank you for considering these public comments on the BMDS PEIS.

Please confirm that you have received my comments.

To: mda.bmds.peis
Subject: Subject: comments for PEIS on proposed Ballistic Missile Defense System

To the Missile Defense Agency (MDA):

The following comments on the environmental and political effects caused by the proposed Ballistic Missile Defense System (MDS) are submitted a day late. I respectfully request that the deadline for submittal of comments be extended for cause. The cause is that there was very little notice to the general public, and only those versed as to the ADAMS or government notice agencies or methods were privy to the proposed invitation to comment.

Comments:

Due to the lateness and my inabilities to absorb the entire contents of the notice in a timely manner I respectfully request that the following be accepted as my comments.

Major deficiencies:

The major deficiencies seem to be the lack of detrimental effects reported in the notice. There will be negative and detrimental effects.

One such effect is that Earth orbital space is gathering 'junk'. This 'junk' makes space incursions dangerous due to the possibility of crashes. Add to this the possibility that the new 'junk' from this program will be armed in various ways, and the detrimental effects suddenly become a major obstacle to the commercialization of space.

Another possible detrimental effect is that we are only now coming into new data on the effects of 'global warming gases' in the upper atmosphere. Some gases which acts as global warming gases at low altitude become global cooling gases at very high atmosphere. Water vapor is such as gas. The global heating effect of such gases in rocket exhaust is not well explored in the notice and deserves better exploration.

International Treaties:

There are several international treaties that affect this BMDS. Since I am not a lawyer, I shall limit my comment on this issue to the request that more concern be shown to the issue of international treaties before any action be taken.

Predicting the future:

Any proposal assumes predictions of the future. Some of these prediction are inadequate. The predictions should contain the experience of the present and the past. This notice does not look adequately at the presently available information.

At a minimum the notice should look at the rate of accumulation of information. What is proposed here does not adequately take into account what we know today.

1. The proposed BMDS can easily be as outmoded as the Maginot Line due to new technologies that are presently being developed. Nanotechnology is on the move. A nanotechnological technique loosed into outer space would easily affect a missile without any of the present technologies able to stop it.
2. EMP weapons are well developed. Hardening a BD against EMP would increase the weight to a point that the missile could not perform its function.
3. Commercials exploitation of space is in its infancy. Adding BMDS which would appear as a danger to tourists is not a great way to make space more commercially exploitable.
4. Other commenters have pointed out many negatives to this approach and I wish to join other commenters in their views of the negatives of BMDS outweighing any positives.
5. This BDMS has the potential to be so costly as to destroy the fiscal soundness of the United States.

Respectfully submitted,
Marvin Lewis

PERCHLORATE AND THE PROPOSED BALLISTIC MISSILE DEFENSE SYSTEM:
COMMENTS ON THE PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT

Lenny Siegel
October, 2004

Executive Summary

The Programmatic Environmental Impact Statement (PEIS) for the Ballistic Missile Defense System (BMDS) not only does an inadequate job of addressing the environmental impact of solid rocket propellant associated with this program, but it seems to ignore the purpose of the National Environmental Policy Act (NEPA). That is, rather than consider how to minimize negative environmental impacts in the design of a program, through "cradle to grave analysis," it uses the environmental document to justify decisions that have already been made.

Furthermore, the PEIS lacks a genuine "No Action Alternative," even though NEPA requires that such an alternative serve a baseline against which to compare the environmental impacts of the other alternatives. In particular, a No Action Alternative that posits little or no use of rocket propellant is essential if the program's proponents are to minimize releases of pollutants—particularly solid rocket propellant and its byproducts—into our nation's water supplies, air, or the upper atmosphere, either by selecting a program alternative or agreeing to binding mitigation measures.

Solid rocket propellant that contains ammonium perchlorate as an oxidizer is designed to generate large quantities of hydrogen chloride, which reacts with moisture in the atmosphere to create hydrochloric acid—that is, acid precipitation. The PEIS should consider how the missile defense program might develop and test alternate launch technologies that are not so environmentally destructive.

DC_E0429

When rockets are launched into the upper atmosphere, they directly deliver hydrogen chloride to the ozone layer, exposing human, other animals, and other biota to the harmful, persistent effects of ultraviolet-B radiation (UVB). Rocket launches are among the largest causes of ozone depletion, and the persistence of such substances from other sources is no excuse for additional pollution. The BMDS program should at the very least evaluate the mitigation of such seriously harmful environmental consequences through the development and deployment of alternative solid rocket propellants.

Perchlorate, primarily from the manufacturing, testing, aborted launches, maintenance, and decommissioning of solid rocket motors, is polluting the drinking water of more than twenty million people and may be endangering natural ecosystems from Cape Canaveral to the Marshall Islands. The PEIS understates the risks of exposure, and it fails to provide data on the quantities of solid rocket propellant likely to be produced, used, released, and disposed by the BMDS. The PEIS should consider the environmental consequences of various disposal strategies so the BMDS program can develop the technology or capacity to address its waste or consider the use of alternative launch technologies or strategies to minimize either the waste or the negative environmental impacts.

Conclusion

To ensure maximum environmental protection and reduce known, widespread human health risks from the use and disposal of solid rocket propellant, the Programmatic Environmental Impact Systems for the Ballistic Missile Defense System should compare the proposed alternatives against a genuine No Action Alternative. At a minimum it should::

1. **Provide more detailed estimates of perchlorate waste likely to be generated by system development, testing, deployment, maintenance, and decommissioning *and* acknowledge emerging regulatory standards for perchlorate exposure.**

2. **Consider in detail the management practices—launch protocols, treatment technologies, etc.—necessary to mitigate the significant environmental impacts, including increased depletion of the stratospheric ozone layer and the likely release of perchlorate into groundwater, surface water, and soil.**

3. **Evaluate alternative launch technologies not based upon ammonium perchlorate.**

Based upon such additional environment review, which I believe is mandated by any fair reading of the National Environmental Policy Act and its implementing regulations, Program Managers should use the information generated to help evaluate all alternatives and to mandate actions to minimize or mitigate the serious environmental consequences associated with such a large and continuing use of solid rocket propellant. Such steps are necessary to protect the American people, the ostensible purpose of the Ballistic Missile Defense System.

Introduction

I have been asked, by Physicians for Social Responsibility-Los Angeles, to review the draft Programmatic Environmental Impact Statement (PEIS) for the Ballistic Missile Defense System (BMDS), with a focus on the environmental impact of solid rocket propellant associated with this program. I find not only that the PEIS does an inadequate job of addressing these impacts, but like many other environmental reviews it seems to ignore the purpose of the National Environmental Policy Act (NEPA). That is, rather than consider how to minimize negative environmental impacts in the design of a program, through "cradle to grave analysis," it uses the environmental document to justify decisions that have already been made.

The PEIS lacks a genuine, "No Action Alternative," as required under NEPA. It rejects evaluation of the alternative, "Cancel Development of Ballistic Missile Defense Capabilities," because it "does not meet the purpose of or need for the proposed action ..." (page 2-68). This approach misunderstands how NEPA works. It is acceptable to evaluate and reject a No Action Alternative because it doesn't meet the purpose of a program, but the environmental impacts of that alternative must be considered as a baseline against which to compare the environmental impacts of the other alternatives.

In particular, a No Action Alternative that posits little or no use of rocket propellant is essential if the program's proponents are to minimize releases of pollutants into our nation's water supplies, air, or the upper atmosphere, either by selecting a program alternative or agreeing to binding mitigation measures.

The bulk of my analysis focuses on the manufacture, use, and disposal of solid rocket propellant containing ammonium perchlorate, because that is the propellant to be most widely used by the Ballistic Missile Defense program. However, liquid propellants, such as the hypergolic propellant containing hydrazine compounds and nitrogen tetroxide, are highly toxic, and the PEIS should consider how to minimize their environmental, health, and safety impacts as well.

At least by number, the 515 projected BMDS launches over the decade beginning this year dwarfs the 99 other projected government launches and the 77 estimated U.S. commercial launched anticipated over the same time period. The environmental review of such a large system, to be developed over a period of many years and potentially deployed for decades, provides an opportunity to reconsider the technologies that our country uses for launching rockets. The draft Programmatic Environmental Impact Statement ignores that opportunity.

Air Emissions

Solid rocket propellant that contains ammonium perchlorate as an oxidizer is designed to generate large quantities of hydrogen chloride. That is, hydrogen chloride is not generated as a product of incomplete combustion of when a system leaks. Rather, it is released as the normal combustion product of the reaction of aluminum and ammonium perchlorate. Then, hydrogen chloride reacts with moisture in the atmosphere to create hydrochloric acid—that is, acid precipitation. The PEIS briefly recognizes this:

> In biomes where rain is a frequent occurrence, launches with solid boosters have an increased likelihood of contributing to acid rain, thereby increasing the amount of HCl deposited in regional surface waters. In areas with low velocity of surface and groundwater movement and relatively shallow ground water table it is possible that deposition of acidic water may impact water resources. The potential for and extent of impact would need to be examined in site-specific environmental analysis. (page 4-60)

Waiting for site-specific analysis in the indefinite future condemns project sites to acid precipitation. There is no hint of how such an environmental impact might be mitigated. The proper analysis, at this stage, is to consider how the missile defense program might develop and test alternate launch technologies that are not so environmentally destructive. That is, the best solution is not likely be site-specific, so the PEIS itself should evaluate this impact.

The PEIS suggests that aluminum oxide, the other major combustion product of solid propellant, is non-toxic. (page 4-60) However, there is some evidence that aluminum in acid environments is toxic to fish.[1] The PEIS should review the literature and reconsider its conclusion based upon the weight of evidence.

Ozone Depletion

Furthermore, when rockets are launched into the upper atmosphere, they directly deliver hydrogen chloride to the ozone layer that protects the Earth against the harmful, persistent effects of ultraviolet-B radiation (UVB). The hydrogen chloride breaks down, releasing chloride ions that trigger catalytic reactions in which one chlorine atom can destroy over 100,000 ozone molecules. I call the delivery of chloride, in the form of rocket exhaust, to the upper atmosphere: "Free-basing the ozone layer."

Increased exposure to ultraviolet radiation causes universal damage to both human health and the natural environment. "… UVB causes nonmelanoma skin cancer and plays a major role in malignant melanoma development. In addition, UVB has been linked to cataracts.… Physiological and developmental processes of plants are affected by UVB radiation…. Scientists have demonstrated a direct reduction in phytoplankton production due to ozone depletion-related increases in UVB.… Solar UVB radiation has been found to cause damage to early developmental stages of fish, shrimp, crab, amphibians and other animals.…"[2]

Once again, the PEIS acknowledges this environmental impact, but it plays it down: "The cumulative impact on stratospheric ozone depletion from launches would be far below and indistinguishable from the effects caused by other natural and man-made causes." (page 4-114). I

[1]See, for example, Baker & Schofield, "Aluminum Toxicity to Fish in Acidic Waters," *Water, Air, and Soil Pollution,* 1987, cited in Heinz J. Mueller, Chief, Environmental Policy Section, Federal Activities Branch, U.S. EPA Region 4, "Environmental Assessment (EA) and Finding for No Significant Impact (FONSI) for the Proposed Titan IV Upgrade Program. Cape Canaveral Air Force Station (CCAFS) and Kennedy Space Center (KSC), FL," letter to Captain Anthony E. Fontana, III, Environmental Planning Division, Regional Civil Engineer, Eastern Region, Department of the Air Force, March 28, 1990.

[2]"The Effects of Ozone Depletion: The Connection Between Ozone Depletion and UVB Radiation," U.S. EPA, June 21, 2004. http://www.epa.gov/ozone/science/effects.html

appreciate the data presented in Appendix I, but the conclusion reached by the authors is implausible.

The PEIS estimates that proposed BMDS launches from 2004 through 2014 would release approximately 1,350,000 kilograms (3,000,000 pounds) of chlorine, primarily in the form of hydrogen chloride, in the stratosphere. Annually, that would be 135,000 kilograms (300,000 pounds). In comparison, official U.S. EPA data estimates annual (2001) U.S. emissions of most destructive industrial ozone-depleting chemicals to total about 50,000,000 kilograms (110,000,000 pounds).[3] Compensating for the chlorine share of the industrial molecules, this means that the potential BMDS launch impact represents about .4% (.004) of the U.S. contribution to ozone depletion.

However, the industrial "emissions" are actually the residuals of production and use of chemical which have been phased out, under the Clean Air Act Amendments of 1990 and a series of international protocols. That is, these substances are already in the environment; nothing can be done to put them back in the bottle. Thus, each year stratospheric releases of rocket fuel exhaust become a larger fraction of the problem, as fewer industrial ozone-depleters are manufactured.

More important, the fractional contribution of rocket-launches to ozone depletion does not make it desirable. It is as large as all but the largest industrial releasers, before the phase-out took effect, and orders of magnitude larger than the releases from a home refrigerator or a car air conditioning system. Our environmental laws and policies do not excuse pollution simply because there are other, larger sources. That is, if I were a repairer of air conditioning systems, I could not—and should not—release chlorine-containing refrigerants into the atmosphere simply because a Titan or Delta launch vehicle emits much more chlorine.

For those unfamiliar with the working of our environmental laws, an analogy in criminal law might be instructive. We don't legalize shoplifting simply because some people conduct million-dollar armored car heists. We may tailor our response to the crime, but we don't say it's acceptable.

Similarly, with the release of ozone-depleting compounds to the atmosphere, we as a society might decide that we shouldn't abruptly end space launches that depend upon solid rocket propellant. Instead, we might set a goal for the deployment of alternatively fueled rockets. The PEIS considers no such goal, despite the urgent need to mitigate global ozone depletion.

The Defense Department, NASA, and others have conducted research on propellants designed to achieve the thrust of ammonium-perchlorate-based fuels without the environmental hazards, but these efforts are poorly funded, and there appears to be no urgency. The BMDS program should at the very least, in its PEIS, evaluate the mitigation of seriously harmful environmental consequences through the development and deployment of alternative solid rocket propellants.

~~[3]"Inventory of U.S. Greenhouse Ga~~s Emissions and Sinks: 1990-2001," EPA 430-R-03-004, April, 2003. http://yosemite.epa.gov/oar/globalwarming.nsf/content/ResourceCenterPublicationsGHGEmissionsUSEmissionsInventory2003.html. Note that these numbers overstate the actual chlorine mass in these emissions, but they exclude less destructive substitute compounds.

Perchlorate Releases

In 1990, when I wrote my report, "No Free Launch,"[4] I focused on the exhaust emissions from solid rocket motors. For the past several years, however, another environmental catastrophe, the pollution of our nation's drinking water with perchlorate, has emerged as a comparable challenge. As many as 20 million people are today drinking water containing perchlorate from rocket fuel production, and hundreds of wells have been taken out of service to avoid further public exposure.

Even in low concentrations, perchlorate in drinking water and food poses a threat to public health, particularly for newborns and other young children. U.S. EPA explains:

> Perchlorate interferes with iodide uptake into the thyroid gland. Because iodide is an essential component of thyroid hormones, perchlorate disrupts how the thyroid functions. In adults, the thyroid helps to regulate metabolism. In children, the thyroid plays a major role in proper development in addition to metabolism. Impairment of thyroid function in expectant mothers may impact the fetus and newborn and result in effects including changes in behavior, delayed development and decreased learning capability. Changes in thyroid hormone levels may also result in thyroid gland tumors. EPA's draft analysis of perchlorate toxicity is that perchlorate's disruption of iodide uptake is the key event leading to changes in development or tumor formation.[5]

Rocket fuel wastes, from manufacturing, testing, training, maintenance, and decommissioning are a significant environmental hazard. This is a front page news story from California to Massachusetts, but it is barely mentioned in the PEIS.

Where it is mentioned, the authors understate the risks of exposure:

> It is now known that perchlorate's direct effects on the human body are limited to the thyroid gland, and only if ingested at very high levels for a prolonged period of time (typically years). Peer-reviewed studies suggest that perchlorate in drinking water below 200 parts per billion has no measurable effect on human health. These findings provide reason to believe that low levels of perchlorate (below 200 parts per billion) also have no measurable effect on pregnant women or fetuses. (Council on Water Quality, 2003) Currently there are no Federal drinking water standards for perchlorate. (4-56)[6]

[4]Lenny Siegel, "No Free Launch: The Toxic Impact of America's Space Programs," National Toxics Campaign Fund, August 1, 1990.

[5]"Perchlorate: Frequently Asked Questions," U.S. EPA, August 5, 2004. http://www.epa.gov/safewater/ccl/perchlorate.html

[6]Note: The cleverly named Council on Water Quality is an association of companies that have released perchlorate pollution into the environment, not a government agency or an unbiased observer.

The reason that there is no federal drinking water standard for perchlorate is that the Defense Department objected to EPA studies that suggested a standard of one part per billion (ppb). Meanwhile, regulatory agencies are using levels far below the 200 ppb asserted in the PEIS. On the way to establishing its own legal standard, California has adopted a Public Health Goal of 6 ppb.[7] In May, 2004, Massachusetts identified a reference dose for perchlorate that would correspond to a 1 ppb drinking water exposure limit. It too is close to promulgating a binding standard.[8] And while U.S. EPA will not promulgate a standard until after the National Academy of Sciences has completed its review, in the interim it has instructed its personnel to use an action level range of 4 to 18 ppb.[9]

The PEIS should offer estimates of the quantities of solid rocket fuel that will be manufactured for the BMDS, not just for testing, but for missiles that will be deployed and hopefully never be launched. From that figure, it can estimate the quantities of manufacturing waste—propellant flakes, chips, and wastewater—likely to be generated. The PEIS estimates that the BMDS program will launch 413 solid-propellant rockets, containing from under 500 kilograms (1,102 pounds) to 60,000 kilograms (132,277 pounds) of solid propellant each. About 70% of that propellant, by weight, will consist of ammonium perchlorate. But nowhere does it estimate what quantity of propellant will be contained in deployed missiles, or even how many missiles will be part of that system. Without that information there is no way to project the amount of propellant waste likely to be generated by the program.

Propellant Disposal

Disposal of missile propellant, for both refurbishing and decommissioning, is a significant financial and environmental cost. NEPA provides the opportunity to weigh those costs before system acquisition, so technological choices that minimize such costs can be considered. The Government Accountability Office (formerly the General Accounting Office) wrote:

> DOD regularly disposes of missiles and has an amount for disposal costs included in its annual budget request. Thus, because it is known at the time of acquisition that costs will be incurred for missile disposal, the probability criterion for recording a liability is met. The Congress has also recognized that disposal costs will be incurred and has emphasized the importance of accumulating and considering this information. For example, the National Defense Authorization Act for Fiscal Year 1995 requires the Secretary of Defense to determine, as early in the acquisition process as feasible, the life-cycle environmental costs for major defense acquisitions programs, including the

[9] Marianne Lamont Horinko, Assistant Administrator, "Memorandum: Status of EPA's Interim Assessment Guidance for Perchlorate," U.S. EPA, January 22, 2003.
http://www.safedrinkingwater.com/community/2003/021203perchlorate_memo.pdf

> materials to be used and methods of disposal. The life-cycle cost estimates are required before proceeding with the major acquisition.[10]

Solid rocket fuel, when deployed in missile systems, does not last indefinitely. It has a shelf life. Both strategic and tactical missiles must be de-fueled and re-fueled or replaced periodically. By 2009, the Army will need to demilitarize over 102,000 Tube-launched, Optically-tracked, Wire-Guided (TOW) tactical anti-tank missiles, and by 2015 over 306,000 Multiple Launch Rocket System (MLRS) rockets will also require demilitarization. These weapons contain over 45,000,000 pounds of ammonium perchlorate, as well as nearly 1,200,000 pounds of RDX and HMX, two other energetic contaminants.[11]

Other missiles become obsolete and require replacement. The Navy reportedly destroyed more than 350 Poseidon Sea-Launch Ballistic Missile second stage motors, each containing 17,000 pounds of solid propellant—about 6,000,000 pounds total—at Hill Air Force Base in Utah, and it is scheduled to be about a third of the way into the destruction of 800 larger Trident I rocket motors.[12]

GAO did not separate disposal requirements for refurbishing from disposal for decommissioning. In 1998, it tabulated over 574,000 missiles and 5,871 large solid rocket motors in the Defense Department inventory, most of which would require disposal.[13]

Yet the PEIS appears not to address the environmental aspects of missile maintenance and it gives only cursory mention to decommissioning:

> Decommissioning of missiles would first require the removal and proper disposal of liquid, solid, or hybrid (liquid and solid combination) propellants from the booster(s). Where possible, propellants would be recovered and reused. Aging motors that contain flaws would likely be decommissioned using open detonation.… Solid rocket propellant would be removed for reclamation or burning in a controlled environment, such as an incinerator. Where practicable, incineration or closed burning of rocket propellant would be performed. Most of the acid and particulates ejected during the burn would be collected in plume scrubber water. This water would be treated for acceptance by a publicly owned (or federally owned) water treatment works in accordance with a National Pollutant Discharge Elimination System (HPDES) permit. (p. 4-16)

Once again, the PEIS authors don't seem to be reading the newspapers. The disposal of solid rocket propellant through "hog-out" (washing out the propellant) or open burning/open detonation are some of the major sources of perchlorate contamination across the country. The

[10] "Financial Management: DOD's Liability for Missile Disposal Can Be Estimated," U.S. General Accounting Office, GAO/AIMD-98-50R, January 7, 1998, page 6.
[11] "Reusing and Disposing of Missile Munitions: Phase 2," U.S. Army Audit Agency, AA 02-145, February 25, 2002, pages 20-21.
[12] "Hill AFB to Destroy 800 Trident Motors, Project Expected to Last 17 Years," *Defense Cleanup,* June 19, 1998, page 4.
[13] "Financial Management," page. 8.

PEIS should note how much propellant will be used, how often it will be necessary to dispose, and what the environmental impacts of each disposal or treatment method are likely to be. Such information is necessary, not just to estimate the life-cycle costs of the program, but also to figure out in advance how to reduce financial costs and environmental impacts through system redesign or ongoing mitigation activities. That's the purpose of the NEPA process.

To its credit, the Defense Department has developed better technologies for treating and recycling solid rocket propellant. For example, the Army Aviation and Missile Command's Research, Development, and Engineering Center uses super-critical ammonia to process and reclaim the ammonium perchlorate from solid propellant. The Hawthorne Army Depot, Nevada, has installed a prototype biodegradation system processing wastewater containing ammonium perchlorate.[14]

However, the Defense Department does not currently have the capacity to dispose of its current missile demilitarization and disposal inventory by any method, let alone the dispose of solid-propellant in an environmentally sound manner.

- Thermal treatment can release dioxins into the atmosphere. Even at very low concentrations, these compounds are a global, persistent threat to public health.
- Open burning and detonation often releases perchlorate into soil and groundwater.
- Recycling means that significant quantities of perchlorate are likely to be used in construction and mining. However, evidence is emerging—from Westford, Massachusetts, for example—that such uses may be generating unacceptable levels of pollution, as well.[15]
- Treatment systems installed to date lack the capacity to treat all the solid or liquid wastes likely to be generated by BMDS manufacture, maintenance, and decommissioning.

Overall, the PEIS puts off consideration of the challenge of waste decommissioning, stating, "The environmental impacts associated with decommissioning of specific components would be more appropriately addressed in subsequent tiered environmental analysis…" (ES-20)

This is unacceptable. It can only lead to "end-of-pipe" solutions, even though the Defense Department's own environmental managers and specialists agree that environmental protection should be integrated into acquisition and even research and development. The 2001 Munitions Action Plan, for example, states:

> The current emphasis in acquisition of munitions of all types (air delivered, ground launched, and sea launched) is on improving accuracy, reliability and increasing distances between firing or launch points and targets (i.e., so-called standoff ranges). At the same time, the public and regulatory bodies are raising concerns about explosives safety and the environmental effects of muni-

> tions. The DoD is also becoming more aware of the cleanup and environmental compliance costs associated with training, testing, demilitarization, and unexploded ordnance (UXO) responses.
>
> These developments have highlighted the need for DoD to address environmental and safety concerns, and costs, throughout the munitions life cycle. This cycle starts from the technology development and design phase to the end-state of use, UXO and munitions constituents cleanup on ranges, or demilitarization. Addressing these concerns early in the life cycle (during requirements definition and acquisition) has the potential to significantly reduce costs and avoid problems later.[16]

That is, if the review of the potential environmental impacts of a system such as the BMDS finds the potential for significant negative environmental impacts, then those designing the system, selecting programmatic alternatives, and managing its testing and deployment should continuously evaluate ways to minimize those impacts, from the beginning.

The PEIS should consider the environmental consequences of various disposal strategies so the BMDS program can develop the technology or capacity to address its waste or consider the use of alternative launch technologies or strategies to minimize either the waste or the negative environmental impacts.

Perchlorate Debris

The PEIS raises and then dismisses the potential environmental impacts from perchlorate debris from launch failure. Presumably the same issues arise if a missile is intercepted before burning all its fuel. It states:

> During flight termination or catastrophic missile failure of solid propellant boosters, pieces of unburned propellant could be dispersed over an ocean area of up to several hundred kilometers. Once in the water, ammonium perchlorate could slowly leach out and would be toxic to plants and animals. In freshwater at 20º C (68º F), it is likely to take over a year for the perchlorate contained in solid propellant to leach out into the water. (Lang et al, 2000, as referenced in U.S. Army Space and Missile Defense Command, 2003) Lower water temperatures and more saline waters would likely slow the leaching of perchlorate from the solid propellant into the water. Over this time, the perchlorate would be diluted in the water and would not reach significant concentrations. (U.S. Army Space and Missile Defense Command, 2003) (page 4-51)

The PEIS authors apparently not followed carefully the research of the Aerospace Corporations team, headed by V.I. Lang, mentioned in their text. This group, which has been

[16] *Munitions Action Plan: Maintaining Readiness through Environmental Stewardship and Enhancement of Explosives Safety in the Life Cycle Management of Munitions,* U.S. Department of Defense Operational and Environmental Executive Steering Committee for Munitions (OEESCM), November, 2001, page 16.

studying perchlorate releases from launch operations for the Air Force, concluded in their most recent report:

> As illustrated by our hypothetical case study, risks associated with the inadvertent release of perchlorate from accidental launch failures must be managed on a case by case basis because of the complexity of variables that can affect the release rate from propellants, and because each launch location has unique environmental characteristics. The same type of approach can be used to assess the risk of perchlorate releases from other operations where sold propellant may be dispersed.
>
> We recommend that a systematic approach to assessing potential impacts be used in the initial planning stages of a launch program, for example, in the AF Environmental Impact Analysis Process, which complies with the National Environmental Policy Act (NEPA). Regulatory agencies may require such analyses be performed prior to new launch programs. In this report, we have presented one type of step-wise approach to assessing perchlorate releases for a typical launch scenario.
>
> Initial studies performed by the University of Alaska on fish exposed to solid propellant in water samples, and in particular on fish exposed to perchlorate in water, indicate the potential for significant biological effects. Studies are also under way to determine the effect of released perchlorate on soil and plant species.[17]

The Army should follow the advice of the Air Force contractors and conduct site-specific analysis of the impact of perchlorate debris on any freshwater lake that might receive perchlorate debris as well as confined oceans waters, such as within the Marshall Islands, where repeated releases of perchlorate could damage sensitive ecosystems or essential food supplies. It should also work with NASA and the Air Force to ground-truth models on perchlorate releases by conducting actual water, soil, and sediment sampling for perchlorate at major launch facilities such as Cape Canaveral and Vandenberg Air Force Base.

Conclusion

To ensure maximum environmental protection and reduce known, widespread human health risks from the use and disposal of solid rocket propellant if the Ballistic Missile Defense System moves forward, the Programmatic Environmental Impact Systems for the Ballistic Missile Defense System should compare the proposed alternatives against a genuine No Action Alternative. At a minimum, to comply with the National Environmental Policy Act, it should::

[17]~~V.I. Lang et al, "Assessment of P~~erchlorate Releases in Launch Operations III," The Aerospace Corporation (No. TR-2003(1306)-2, prepared for the Air Force Space Command Space and Missile Systems Center (SMC-TR-04-11), September 18, 2003, page 27. This and other valuable Air Force/Aerospace Corporation studies on the likely environmental impacts of space launches may be found at http://ax.losangeles.af.mil/axf/studies/studypage.htm.

1. **Provide more detailed estimates of perchlorate waste likely to be generated by system development, testing, deployment, maintenance, and decommissioning *and* acknowledge emerging regulatory standards for perchlorate exposure.**

2. **Consider in detail the management practices—launch protocols, treatment technologies, etc.—necessary to mitigate the significant environmental impacts, including increased depletion of the stratospheric ozone layer and the likely release of perchlorate into groundwater, surface water, and soil.**

3. **Evaluate alternative launch technologies not based upon ammonium perchlorate.**

Based upon such additional environment review, which I believe is mandated by any fair reading of the National Environmental Policy Act and its implementing regulations, Program Managers should use the information generated to help evaluate all alternatives and to mandate actions to minimize or mitigate the serious environmental consequences associated with such a large and continuing use of solid rocket propellant. Such steps are necessary to protect the American people, the ostensible purpose of the Ballistic Missile Defense System.

Subject: PEIS Noise section comment

In Section 3.1.10 - Noise, there are numerous errors.

An increase of 1 dB is not a doubling of sound energy. Decibel are on a quasi-logrithmic scale and it does not function like the Richter scale. An increase of 3 dB is a doubling of sound pressure.

dBA is not used to assess human reaction to a single noise event averaged over a 24-hour period. dBA is measure of sound pressure using the A-weighted scale. Many other acoustical metric are used to assess human reaction, including Leq - equivalent noise level, sound exposure level, Ldn, etc.

It is obvious that this section was written by someone without knowledge of basic acoustics. This section should be re-done by an acoustician. If there is a complete misunderstanding of noise, how can the impacts be correctly assessed?

Subject: BMDS PEIS Comments: Correction of Typos

Dear MDA
1) Did the MDA extend the deadline for BMDS PEIS comments and organize additional hearings to enable citizens in regions more affected by the BMDS to attend hearings and comment? This was requested at the Sacramento hearing.

2) I discovered typos in the BMDS PEIS comments that I submitted earlier. If possible, could you replace my BMDS PEIS comments that I submitted a couple of days ago with my edited comments below. The edited typos are in parts of only nine sentences. If needed, I will be happy to indicate the edits.

Please let me know if you can substitute my BMDS PEIS comments below for the ones I submitted earlier.

Thank You and may you have a happy Thanksgiving holiday

Comments:

November 17, 2004

Dear US Missile Defense Agency (MDA);

Please consider the following comments on the Draft Programmatic Environmental Impact Statement (PEIS) of the Ballistic Missile Defense System (BMDS).

1) Addressing Scoping Comments: I submitted a number of comments, on the scope of the BMDS several of which appear to have not been adequately addressed in the draft BMDS PEIS. These will be addressed in each specific comment. As discussed with Mda officials at the Sacramento public hearing, the MDA should provide more time for additional individuals from the most affected regions, including California and Alaska to comment on the BMDS PEIS.

2) Security, freedom, civil liberties, prosperity, the rule of law and the defense of the US constitution and its environment are very important to me as a citizen of this great country. Environmental sustainability is indelibly tied to our prosperity, and more abstractly to our security and freedom. We all want to be safe from missile attack. However, I am very concerned about the interconnected environmental, security and arms proliferation consequences of the US Missile Defense Agency (MDA) plans to establish a vast land, air, sea, and space- based Ballistic Missile Defense System (BMDS) including interceptor and laser weapon systems, sensors and command and control communication systems. The BMDS presents a number of toxic contamination and exposure risks as well as risks to **health and safety** that must be considered under the National Environmental Policy Act (NEPA). In so many cases the BMDS PEIS under estimates the magnitude or importance of these risks. These underestimates of environmental effects will be discussed under specific comments.

3) The BMDS PEIS does not include a real "No Action Alternative". Such an alternative that does not include further development testing or deployment of these weapon systems needs to be considered and included in the PEIS. The BMDS PEIS has not considered the "No action Alternative" of re-joining the UN and many nations of the world in working to enhance security through treaties and arms control and disarmament approaches, e.g. the approach that has provided us with long-term security to date.

4) The BMDS does not consider the direct, indirect and cumulative effects of the BMDS as required by NEPA, especially in regard the effects of the BMDS on the Arms race, which puts us closer to the disaster of nuclear war. In this regard, the PEIS is completely lacking a non-proliferation analysis. The BMDS tries to sell missile defenses to the public as a way to go beyond nuclear deterrence. Yet the BMDS is a dramatic escalation of a missile defenses that is not relevant for defending from terrorists who are much more likely to smuggle WMD. Securing loose nuclear materials is a much more effective strategy for preventing such terrorist nuclear threats.
The BMDS PEIS ignores the fact that the US posses extensive offensive nuclear and conventional weapon systems and that the proposed BMDS will operate along side these offensive weapon systems. The BMDS PEIS ignores the fact that the U.S. has a preemptive nuclear and conventional first-strike warfare policy and has exercised this policy in preemptively / preventatively invading other countries that have not attacked the U.S. including Iraq. Pronouncements of US preemptive offensive nuclear and conventional first strike policy as articulated in the 2002 Nuclear Posture Review; the 2002 Defense Guidance Policy; many statements of Bush, Cheney, Rumsfeld, and Wolfowitz, as well as the unprovoked 2003 invasion of Iraq, have together furthered international fears of the prospect of unprovoked unilateral attacks by the US. Building a massive land, sea, air and spaced-based BMDS is very likely to further invoke international fears that it will be used in conjunction with US offensive first strike and command and control communication systems to attack and/or dominate other countries.

The BMDS PEIS ignores the reasonable forseeability that it forces other nations to proliferate and/or smuggle WMD so that they can re-establish deterrence. Indeed, Russia and China have already started to proliferate and develop counter measures in response to the impending development of the U.S. BMDS (Evans 2004). Previously non-nuclear nations such as North Korea have stated that they also proliferated in order to establish a deterrent. In short, many nations are concerned that a US BMDS will eliminate their ability to deter attack, and assure the ability of U.S. forces to intervene anywhere in the world with offensive weapons systems. Such fear and insecurity has a reasonable forseeability of driving WMD proliferation and thereby decreasing rather than increase our security for years to come.

Such WMD proliferation and the treat of nuclear war will have major environmental consequences. Thus, the BMDS needs a non-proliferation analysis which considers the direct, indirect and cumulative effects of the BMDS as well as other entities.

In essence, the combined direct, indirect and cumulative effects of the proposed BMDS in conjunction with US offensive weapon systems and US preemptive first strike military policy is very likely to invoke fear of US actions and intentions. Furthermore, a BMDS would be much more likely to be effective in intercepting ICBMs of another nation, if the BMDS were to be used following a preemptive nuclear first strike. Since the nation that strikes second loses for sure, the BMDS destabilizes the policy of nuclear deterrence that has helped to keep the peace for over 50 years. There is more than a reasonable foreseeability that the resulting paranoia will cause a major arms race, and push us into confrontations and wars of great scale. Such wars seriously threaten all we as a people hold dear; health, safety, and our environment.
The threat of the BMDS leading to a more aggressive nuclear policy and nuclear war can be seen in the historic article "Victory is Possible" by Colin S. Gray and Keith Payne, Foreign Policy Summer 1980, pp. 14-27. These authors state: "If American nuclear power is to support U.S. foreign policy objectives, the United States must possess the ability to wage nuclear war rationallyŠ.
"ŠThe United States should plan to defeat the Soviet state and to do so at a cost that would not prohibit U.S. recoveryŠ.
Washington should identify war aims that in the last resort would contemplate the destruction of Soviet political authority and the emergence of a postwar world order compatible with Western valuesŠ.
Once the defeat of the Soviet state is established as a war aim, defense professionals should attempt to identify an optimum targeting plan for the accomplishment of that goal. For example, Soviet political control of its territory in Central Asia and in the Far East could be weakened by discriminate nuclear targeting. The same applies to Transcaucasia and Eastern EuropeŠ.
Strategists cannot offer painless conflicts or guarantee that their preferred posture and doctrine promise a greatly superior deterrence posture to current American schemes. But, they can claim that an intelligent U.S. offensive strategy, wedded to homeland defenses, should reduce U.S. casualties to approximately 20 million, which should render U.S. strategic threats more credible. Š
A combination of counterforce offensive targeting, civil defense, and ballistic missile and air defense should hold U.S. casualties down to a level compatible with national survival and recovery. The actual number would depend on several factors, some of which the United States could control (the level of U.S. homeland defenses); some of which it could influence (the weight and character of the Soviet attack); and some of which might evade anybody's ability to control or influence (for example, the weather). Š
No matter how grave the Soviet offense, a U.S. president cannot credibly threaten and should not launch a strategic nuclear strike if expected U.S. casualties are likely to involve 100 million or more American citizens." Š (**Victory is Possible** by Colin S. Gray and Keith Payne *Foreign Policy*, Summer 1980, pp. 14-27).
Note that these authors also helped to write the 2002 US Nuclear Posture review, which further solidifies the US preemptive nuclear first strike policy. Gray and Payne make it clear that BMD is essential for a more aggressive US nuclear first strike policy. Thus, there is a reasonable foreseeability that the BMDS in conjunction with US offensive nuclear forces will increase the probability of a massive nuclear war. Thus, the BMDS needs to include a detailed analysis of the environmental effects of "limited" and "all out" nuclear war, including: medical radiological, blast, burn, fallout, disease, and cancer effects to health and safety; effects on nuclear winter, as well as effects on atmosphere, global supplies of fresh water, global food supplies, and nuclear power plants and power systems. The prospect of the BMDS leading to more aggressive US policies that result in a massive nuclear war also needs to be considered in regard to a true no action alternative.
In short, since there is a reasonable forseeability that the BMDS in conjunction with US and Allied nuclear weapon systems and current US nuclear weapons policy as defined in the 2002 Nuclear policy

review will destabilize the nuclear arms race and lead to nuclear war, the environmental consequences of nuclear war need to be considered in detail in the BMDS PEIS. (Ambio Volume XI number 2-3, 1982, Nuclear War: The Aftermath. Entire journal dedicated to the effects of nuclear war, including effects on heath and safety, Air, water resources, agriculture, biological resources, and nuclear winter.) This request in my scoping comments was ignored. e.g. Scoping comment "#18) The MDA needs to consider whether the BMDS in conjunction with offensive first strike weapon systems and first strike policy increase the probably of a major nuclear war or other disturbance that could result in nuclear Winter, with the associated loss of species"

5) **The BMDS PEIS did not adequately consider impacts of Hazardous waste and materials and on Health and safety, Water Resources and Biological resources of environmental contamination from toxic and hazardous components of rocket fuels and explosives.**
The BMDS PEIS markedly under reports the emissions of representative interceptors. Exhibit 4-11 reports the emission of (90+58+52+22+17+6+6)=251 pounds for a representative interceptor. However, ground based interceptors are much larger (approximately 54 feet long 3 stage solid propellant rockets (such as the Minuteman III) weighting 22.5 to 25 tons and containing approximately 30,000 to 45,000 pounds of solid propellant. Thus the MDA underestimates the emissions from such interceptor rockets by factor of greater than 100. This is totally unacceptable. This underestimate of BMDS pollutants is apparently repeated in Exhibits 4-13, 4-14 and 4-15. Thus the MDA needs to revaluate the environmental effects of these pollutants. Also the MDA should define what are the emissions from the missiles used to launch spaced based interceptors, and sensors.

6) Not only does the BMDS PEIS under represent the total amount of emissions, from the estimated 515 BMDS rocket launches over the next several years, it also discounts that this program will be injecting large quantities of chemicals including aluminum oxide, hydrogen chloride and hydrochloric acid into the upper atmosphere, stratosphere, etc. Most concerning is the injection of hydrogen chloride into the upper atmosphere where the breakdown of each hydrogen chloride molecule to chloride ion catalyzed the breakdown of 100,000 ozone molecules, thereby depleting ozone, and decreasing the blocking of UV rays. This depletion of ozone will increase risk of cataracts and skin cancer. Thus, the BMDS will have a much greater effect on ozone depletion and skin cancer than HCl released at sea level.

7) Liquid propellants containing hydrazines, nitrogen tetroxide, and other compounds are highly toxic. At very low concentrations, hydrazines irreversibly cross link to aldehyde groups on proteins at slightly acidic pH and can cause cancer. One of the most concerning pollutants from the firing of rocket engines is HCl, which combines with atmospheric water to produce acid rain. The PEIS did not address potential for interactions between HCl and hydrazines commonly used in rocket engines such as monomethylhydrazine (MMH) and Unsymmetric dimethylhydrazine (UDMH). Specifically does the toxicity of hydrazine increase under acidic conditions found in acidic rocket exhaust?

8) Ammonium perchlorate is one of the main components of rocket fuel, typically constituting 60% to 75% of missile propellant and about 70% of space shuttle rocket motors. Since the fuel and perchlorate goes flat, the fuel/perchlorate has to be replaced every few years or it will fail to function properly, thereby increasing the amount of perchlorate waste and exposure problems.
Ammonium Perchlorate is well characterized as a thyroid hormone disruptor.
http://www.ewg.org/reports/rocketscience/chap3.html . **At high enough concentrations, perchlorate can affect thyroid gland functions, where it blocks iodide uptake necessary for the synthesis of thyroid hormones (Urbansky 2002). Perchlorate can cause hypothyroidism, and thyroid cancer.** The environmental levels of perchlorate have been shown to inhibit development in frogs (Goleman et al. 2002). California has extensive perchlorate contamination problems with the drinking water sources of at least 7 million Californians and millions of other Americans are contaminated with perchlorate. A federal **safe daily perchlorate exposure has not yet been set by the**

EPA, and its expected release in 2002 has been delayed. It has been delayed since the DoD objected to EPA studies suggested a standard of 1 ppb. Senator Barbara Boxer has introduced legislation to require the EPA to establish a standard for perchlorate contamination by July 1, 2004. While most contaminated samples are in the 4 to 20 ppb levels, surveys of California water sources show several sites with perchlorate levels from 4 to 820 ppb.
http://www.ewg.org/reports/rocketwater/table1.php
Ammonium perchlorate used in solid propellants blocks the formation of key thyroid hormones which are critical for growth and development especially in fetuses and children. The PEIS proposes to allow over 30-fold higher levels of perchlorate (200 parts per billion) than that proposed by the State of California (6 parts per billion). As pointed out in the comments of Lenny Siegel: The reason that there is no federal drinking water standard for perchlorate is that the Defense Department objected to EPA studies that suggested a standard of one part per billion (ppb). Meanwhile, regulatory agencies are using levels far below the 200 ppb asserted in the PEIS. On the way to establishing its own legal standard, California has adopted a Public Health Goal of 6 ppb (Frequently Asked Questions (FAQs) About the Public Health Goal for Perchlorate," California Office of Environmental Health Hazard Assessment (OEHHA), March 11, 2004. http://www.oehha.ca.gov/public_info/facts/perchloratefacts.html). Even these levels of perchlorate may be detrimental to fetuses and infants. The human study considered in setting the California public health goal did not evaluate pregnant women, fetuses or infants (Greer et al. 2002). The study of Greer at al 2002, only used a 14-day exposure to perchlorate, which is insufficient to deplete thyroid colloid which acts as a storage form of thyroid hormones. Thus this study is insufficient to estimate the effect of long-term perchlorate exposure on iodine uptake or thyroid hormone levels. Since the effect of long term perchlorate exposure on reducing thyroid hormone levels, especially in the fetus and in infants has not been considered, the MDA needs to evaluate these effects on these sensitive groups as required by federal law. In May, 2004, Massachusetts identified a reference dose for perchlorate that would correspond to a 1 ppb drinking water exposure limit. Also note that perchlorate is found in milk and in several plant species, including lettuce, where high levels have been reported. Thus multiple sources of perchlorate exposure need to be considered.

9) To ensure maximum environmental protection and reduce known, widespread human health risks from the use and disposal of rocket propellants, the BMDS PEIS should compare the proposed alternatives against a real No Action Alternative. At a minimum the BMDS PEIS should:
A. Acknowledge and address emerging regulatory standards for perchlorate exposure.
B. Consider the effects of perchlorate on susceptible subpopulations, including fetuses, and children. The MDA also needs to consider the effects of perchlorate exposure on even more sensitive congenitally hypothyroid populations, so that these individuals are not detrimentally affected by perchlorate from BMDS missile launches.
C. Since water supplies in several regions of central and southern California are already at, exceeding and in some cases markedly exceeding the emerging regulatory standards for perchlorate, the MDA should acknowledge and address the perchlorate problem so as to protect the public.
10**) The BMDS PEIS did not address my scoping comments that the** PEIS should address whether BMDS testing and deploying interceptors endanger Health and Safety by their targeting the incorrect vehicle, e.g. civilian aircraft. The BMDS as described on the MDA web site is a risk to public safety as shown by the Patriot 3 (PAC-3) shooting down US and Allied British military planes during the 2003 US / British invasion of Iraq. According to a report in USA Today April 15, 2003, titled "Patriot Missile: Friend Or Foe To Allied Troops?" By Andrea Stone, It is seemed that the Patriot has difficulty determining "friend from foe". In the first incident, on March 22, a Patriot missile downed a British Tornado GR4 fighter-bomber near the Iraq-Kuwait border, killing the two-man British crew. A U.S. F-16 fighter jet had to fire on a Patriot missile radar in Iraqi after the radar "locked on" to the jet. A Patriot-3 battery was also suspected in the downing of a U.S. Navy F/A-18 Hornet near Karbala on April 2, killing the pilot. Since several other Patriot friendly fire malfunctions are known, the MDA needs to consider how many civilians will be killed by the patriot BMDS.

Furthermore, the Aegis Cruiser system is a threat to commercial aircraft, as shown by the USS Vincennes mistakenly shooting down the Iranian Airbus commercial airliner flight 655 on July 3, 1988, killing all 290 civilians aboard http://www.geocities.com/CapitolHill/5260/vince.html . Over 100 witnesses reported seeing an upward arching flash of light immediately before TWA flight 800 exploded off of New York. However, government investigators refused to consider whether a missile launched from an unannounced ongoing naval exercise could have been the cause of the crash. The point is that the activation of BMDS risks accidentally shooting down civilian airliners, which was not even considered in the BMDS. While the BMDS states that warning will be provided to enable time to clear the airspace, it is highly doubtful that such time would be allowed in a perceived emergency. The BMDS PEIS needs to address these threats.

Both the PAC-3 and Aegis Cruisers are included as components of the proposed BMDS Since the PAC-3 is a relatively short range system and is not designed for intercepting ICBMs, how many PAC-3 batteries will have to be deployed to offer full protection for the American and allied cities and military bases. Are these within range of any civilian aircraft? How will they discriminate attacking aircraft from commercial and civilian aircraft? The MDA needs to consider how many civilians and US/allied military personnel will be accidentally killed by the BMDS.

11) The PEIS provides conflicting information on the effects of the ABL on health and safety. The PEIS does not quantitatively assess the risk of the Airborne Weapons Laser (in a Boeing 747) blinding pilots and/or other civilians, stating mainly that humans and others would be exposed to the laser beam, mainly as reflected light for less than 0.01 seconds. However the PEIS provides no data on the wattage or power of these lasers in the PEIS making it impossible to assess the dangers of such laser exposure, especially to the eyes.
On Oct. 30, 1995, a Southwest Airlines' pilot in control of a flight departing McCarran International Airport in Las Vegas was temporarily blinded by a laser light. According to news reports, the incident was serious enough to force the plane's captain to take control until the pilot regained his sight. "Had it hit me and the other pilot simultaneously, I shudder to think what would have happened," the pilot told reporters. (http://www.fda.gov/fdac/departs/496_irs.html). Had the pilot been exposed to a high energy laser (HEL) as used in the BMDS the results could be much more debilitating, endangering the health and safety of numerous passengers.
The BMDS PEIS (page 4-32) cites that exposure to a reflected laser beam while in the air operating environment would be very short, < 0.01 seconds that and would not impact the health and safety (US Air Force 1997A). But no estimates are provided for the actual danger zone for the HEL to detrimentally affect health and safety, e.g. causing skin and especially retinal damage, if the HEL or other lasers are directed at plants, animals, or people. The Draft Supplemental Environmental Impact Statement for the Airborne Laser Program (2002) (page 99) cites the power of the HEL as about 10 million watts per square centimeter. Ten million watts per square centimeter will burn retinas and eyeballs very quickly. The PEIS states that medium energy lasers such as the SHEL if focused at point 12 km away, would be hazardous to the human eye 2 km before to 2 km past the focus point. Where as, the other lasers and especially the HEL would be hazardous immediately after leaving the turret of the ABL. While the PEIS states that the BILL and TILL no hazard distance would extend > 10 km beyond the target, and the HEL hazard distance would extend even beyond these distances. But the BILL, TILL and I presume the HEL hazard distances are apparently classified. How can the public comment on the effects of the BILL TILL and especially the HEL on health and safety if the of distance at which these lasers cause eye damage is not available? The public and the MDA / Air force need to make this information available to better ensure the heath and safety of the public.

The PEIS focuses on the testing of these lasers, but fails to reveal whether once deployed, the ABL or any other BMDS weapons lasers will ever be directed toward aircraft including airliners, or individuals on the surface of the earth, e.g. on land or at sea. If so, the MDA needs to address the effects of HEL

and other weapons lasers on endangering health and safety, especially skin and eye damage.
12) The MDA PEIS needs to consider whether boost phase BMDS interceptors could be launched erroneously, causing another country to believe it was under attack, and thereby triggering a nuclear war. The American Physical Society examined the issue of boost phase intercept, and determined that the interceptor has to be very close to the ICBM, be launched within about 15-60 seconds from the time the ICBM was launched, and have much greater accelerations than the ICBM http://www.physicstoday.org/vol-57/iss-1/p30.html (Kleppner et al. 2004). The problem of boost Phase intercept is greater for solid rockets with high accelerations than for slower accelerating liquid rockets. The further problem is that ship based interceptors are not big enough and do not have sufficient accelerations to make a boost phase intercept even from a small country like North Korea. If it did intercept, it is likely the warhead would not be destroyed by a kinetic hit-to-kill interceptor and would continue on to near its intended destination. Finally, they point out that a boost phase launch intercept of a ICBM from North Korea would likely occur over northern China, further risking causing China to think it was under attack by the US which could cause a nuclear war (Kleppner et al. 2004). The BMDS needs to consider the realities of the limitations of any BMDS relative to a real no-action alternative of working toward disarmament through arms control treaties.

13) Space debris from high altitude, mid-course missile intercepts or destruction of satellites. The PEIS does mention that even tiny particles of space debris traveling at extremely high speeds in orbit can destroy space suits, rockets and satellites. While the PEIS correctly points out that debris from low orbital intercepts will decelerate once it hits the atmosphere, and thereby de-orbit. However the PEIS fails to consider the space debris from high altitude intercepts which risk producing space debris that could make space unusable for many years. While the PEIS considers testing the BMDS on "targets of opportunity", no mention is made of space debris resulting if other nations target US BMDS satellites or components in high orbit as "targets of opportunity". This must be considered since the resulting space debris could destroy objects in space, making space unusable as well as violating the 1967 space treaty.

14) The environmental consequences of many rocket launches needed to deploy and maintain space-based interceptors has not been adequately considered, nor has the environmental consequences of their fuel. Will space-based satellites/interceptors use nuclear power sources? Will any BMDS interceptors ever use nuclear warheads? While nuclear tipped-interceptors are not mentioned in the PEIS, per se. In Section 2.2.1.1 the PEIS does mention the possibly of destroying a missile by using interceptors with directed blast fragmentation kill vehicles. However the PEIS, fails to reveal the nature of the blast fragmentation device, which is needed for evaluation of its environmental effects. Instead the MDA PEIS states that "the interceptors will be discussed and analyzed for environmental impacts at the booster and kill vehicle level. This will allow the MDA the flexibility to configure new interceptors based on boosters and kill vehicles analyzed in this document to address new or emerging threats." This does not allow a satisfactory evaluation of the hazards of the BMDS components. What blast fragmentation devices will be used? The PEIS needs to include the details of chemical and toxicant use and exposure.

15) Radioactive and/or biological weapons fallout from intercepted missiles has not been considered in the PEIS. If a kinetic hit to kill interceptor knocks out an ICBM in the mid phase or terminal phase, the nuclear warhead or its fragments are going to produce a tremendous amount of radioactive contamination where ever they land. Such radioactive fallout will clearly have major, highly deleterious effects on adults, children, and especially on developing embryos, and fetuses. While such an interception is very likely to be highly preferable to damage resulting from an air or ground burst over a city, the resulting radioactive contamination needs to be considered. The effects of war are normally excluded from analysis by the National Environmental Policy Act (NEPA). However, the proposed BMDS action is very likely to provoke a worldwide WMD arms race, and force other nations to prepare to launch a massive retaliation against the US should war ensue. Thus, these effects need to be

considered relative to a real no action alternative. Since the proposed BMDS is very likely to cause a massive arms race, the environmental consequences of a resulting War involving nuclear or other WMD should not be ignored. The PEIS needs to consider the environmental effects of fallout from intercepted WMD as well as the effects of WMD the BMDS fails to intercept. Thus PIES needs to consider these hazardous waste and materials issues. Appropriate references include "The Effects of Nuclear Weapons, Compiled and Edited by Samuel Glasstone and Philip Dolan, third Ed. DOD, DOE. 1977.

The American Physical society also identified the issue that boost phase intercept has a high probability of munitions carryover. A successful boost phase intercept is unlikely to disable ICBM's warheads or munitions. They will be deflected only slightly, if at all, and will continue on ballistic trajectories (Kleppner et al. 2004).

16) Will any interceptors use nuclear warheads? The PEIS does not address the inability of mid-course or terminal kinetic interceptors to stop a "threat cloud" once a attack missile has MIRVed, or released many decoys or countermeasures (Richard L. Garwin. Holes in the Missile Shield. Scientific American, November 2004, page 70-79). The MDA may be temped to intercept such a threat by using large nuclear tipped interceptors. The potential use of nuclear tipped interceptors was discussed by high ranking US DOD officials in 2002 http://www.washingtonpost.com/ac2/wp-dyn/A28866-2002Apr10?language=printer. If such nuclear tipped interceptors were deployed, the environmental risks would be much greater. If so, the environmental consequences of the nuclear fallout and electromagnetic pulses from such high altitude nuclear detonations must be considered in detail. This would include analysis of risks to health and safety, contamination of water, land, soils, EMP effects on civilian and medical electrical and computer systems and infrastructure. The MDA should also consider the effects of radioactive fallout on health and safety, biological resources, and contamination of land and water resources.
Furthermore, given the historic 15% missile launch failure rate, the radioactive fallout from accidents with nuclear tipped interceptors must be considered in detail. The public should have full opportunity to consider and comment on the use of such nuclear tipped interceptors in this PEIS. The point is that the blast fragmentation devices need to be described in detail to enable adequate evaluation of its environmental effects.

17) Also note that the technology and environmental effects of "advanced systems" remain to be defined. How can the environment effects of an undefined "advanced system" be evaluated in this PEIS? A full environmental analysis is needed for each component of the PEIS to be added. If any component of the BMDS will ever use nuclear warheads in any interceptors the MDA needs to thoroughly consider the environmental effects, as discussed above.

18) Will any MDA interceptors or Lasers use anti-matter weapons? A US Air Force anti-mater weapons research programs has recently been described in the SF Chronicle http://sfgate.com/cgi-bin/article.cgi?file=/c/a/2004/10/04/MNGM393GPK1.DTL. IF the BMDS will use antimatter weapons or energy sources, the environmental effects including the health and safety risks, and chemical exposure risks need to be described in detail.

19) **The BMDS PEIS needs to consider direct, indirect and cumulative effects of the proposed project in conjunction with other federal offensive military weapons systems and policies were not addressed**, but need to be addressed. The National Environmental Policy Act (NEPA) (http://ceq.eh.doe.gov/nepa/regs/nepa/nepaeqia.htm) and especially **The Regulations for Implementing NEPA** (http://ceq.eh.doe.gov/nepa/regs/ceq/toc_ceq.htm), state that both the direct and indirect effects of the proposed project as well as the Cumulative impact of the project should be considered. Sec. 1508.7 States that the "Cumulative impact" is the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably

foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time.
In the context of this global ballistic missile defense system, the cumulative impact of reasonably foreseeable future actions of the US as well as other nations, agencies and persons need to be considered. Yet the reasonable foreseeable actions of other nations and individuals responding to the BMDS by proliferating WMD was not considered by the MDA in this PEIS.
As stated in Sec. 1508.8 "Effects" include:(a) Direct effects, which are caused by the action and occur at the same time and place and (b) Indirect effects, which are caused by the action and are later in time or farther removed in distance, but are still reasonably foreseeable. Effects and impacts as used in these regulations are synonymous. Effects includes ecological (such as the effects on natural resources and on the components, structures, and functioning of affected ecosystems), aesthetic, historic, cultural, economic, social, or health, whether direct, indirect, or cumulative. Effects may also include those resulting from actions which may have both beneficial and detrimental effects, even if on balance the agency believes that the effect will be beneficial.
Thus, by law the MDA also needs to consider the Direct, Indirect and Cumulative impacts on the environment of the proposed BMDS along with other US offensive weapons systems and stated & demonstrated US preemptive first-strike policy.

The following points are points that need to be considered in the no action alternative.
20) The PEIS needs to consider whether the BMDS will result in Proliferation of Weapons of Mass Destruction (WMD) and an arms race in space. The response of other nations to the BMDS has not been considered. Specifically, the BMDS is coupled to other offensive weapons programs and will force other nations to proliferate and/or smuggle WMD so that they can re-establish deterrence. Relatively inexpensive countermeasures to BMD will likely thwart the goals of BMD. Such proliferation coupled with increased international tension will decrease rather than increase our security and lock us in to an expensive and destabilizing arms race and will have devastating long-term environmental consequences.

21) Alternative 3: Not developing, or building the BMDS or any of its components and instead renegotating an expanded and verifiable ABM / BMDS treaty: The ABM treaty helped to stabilize and de-escalate the nuclear arms race for all of its 29 years of existence. No country dared attack the US with nuclear missiles, in part because the U.S. would know exactly where the missile came from and have the clear ability to retaliate and bomb them into obivilion. That is certainly still the case. This option would preserve deterrence and peace. Yet it would enable the nuclear nations to abide by the NPT and reduce the overall level of nuclear weapons, in exchange for non-nuclear nations not developing nuclear weapons.

22) Alternative 4: Preserving Space for non-military purposes. The MDA should consider the alternative of not militarizing space. The planned US militarization and domination of space as described in the US Space Command Vision for 2020 (http://www.fas.org/spp/military/docops/usspac/lrp/ch02.htm) and as described in the 2002 US defense guidance policy and elsewhere, will certainly create and intensify conflicts over the control of space for years to come. These US policy documents talk about "Full Spectrum Domination", "negating" or "destroying" the enemy's satellites and use of space. As US citizens we would like for the US to protect space from militarization, but do we want the US to dominate space, and to start a series of space wars? Think about how you would feel if you lived in another nation and some one destroyed your satellites. Would such actions be considered an act of war?
Additionally how does the BMDS PEIS affect US compliance with the Outer Space Treaty?

23) Alternative 5: Deployment of a much more limited land and or Sea based theatre BMD that

DC_E0439

would offer protection from attack by short or intermediate range missiles. For example, rather than develop the extensive land, Sea, air and space based system, the US and its allies could instead deploy a currently available Aegis missile cruiser(s) off of North Korea. Such a small, affordable, alternative system would immediately meet the needs of defending Japan against missiles that might be launched by North Korea without invoking fears that it would be used to enable invasions and/or domination of the world and thereby starting a massive global arms race.

24) NONPROLIFERATION ANALYSIS COMMENT
Based on my expertise in the area of genetics, physiology, toxicology and nuclear weapons control/non-proliferation, it is a **reasonable foreseeability** and in my opinion a very high probability that the proposed BMDS creates a significant risk of nuclear and biological weapons proliferation. This proliferation risk goes hand in hand with a greater security risk, and both increase the potential harm to the environment and the public.

As pointed out by Nicole C. Evans, National missile defenses may undermine strategic stability by threatening the ability of other countries to retaliate, which is the core of their deterrence. Theater missile defenses do not pose this danger (Evans 2004). Evans goes on to describe Russian and Chinese concerns to National Missile Defense (NMD) and especially Global Missile Defense (GMD) as described in the BMDS PEIS. She also describes how Russia and China have already started to proliferate in response to the US renigging on the ABM treaty and preparing to deploy GMD, e.g. the BMDS.

Evans points out that; "Russia and China share two key concerns about American missile defense plans: that their nuclear deterrent is threatened and that American missile defense plans will destabilize arms control. Š
Both Russia and China have responded actively to the American abandonment of the ABM Treaty by developing asymmetrical measures to neutralize any potential threat. By withdrawing from START II, Russia was able to continue deploying multiple independently targetable reentry vehicles (MIRVs) on intercontinental ballistic missiles (ICBMs). Putin announced in October 2003 that Moscow intends to place on combat duty dozens of MIRVed SS-19s, and Russia has also extended the service life of its SS-18 heavy ICBMs. Russia has begun building the fourth-generation *Borey* class of submarines, is MIRVing its silo-based Topol-M, and is finishing testing the mobile version of the Topol-M." In February 2004 Russia also "successfully tested a new hypersonic "Crazy Ivan" warhead that follows a nonclassical scenario, changing flight altitude and course repeatedly, making it nearly impossible to track and target." Evans also points out that "Russia has also upgraded the A-135 strategic single-site ABM system covering Moscow, the only such system currently in operation. In 2002, Russia began working in earnest on TMD and is currently developing several advanced missile interceptors (Evans 2004).

Evans points out that "Both Russia and China appear unconvinced by American assurances that global missile defense is not directed against them, despite echoing American rhetoric about the need to defend against the terrorist threat. Senior Russian military and foreign affairs officials have argued that while the United States proclaims its partnership with Russia, its actions show anything but that. ŠRussian concerns are further aggravated by America's stated intention not to cut its nuclear arsenal to levels designated by the Moscow Treaty of May 2002--instead moving the missiles as well as the warheads into storage as a hedge against an uncertain future." (Evans 2004).

Evans then goes on to describe how China is responding to the US BMDS threat and "is moving toward a more diversified, invulnerable, and combat-ready operational nuclear triad." "Second, Russia and China are very concerned that American missile defense plans will destabilize existing arms control regimes and forestall future agreements."

DC_E0439

Russia, China, and other states express deep concern about the weaponization of space. In 2003, Russia and China proposed an agreement for the non-weaponization of space, and negotiations continue at the Conference on Disarmament in Geneva. Both Moscow and Beijing maintain that nonproliferation measures and policing regimes are a better way of dealing with weapons of mass destruction than attempts to develop missile shields" (Evans 2004).
Evans Concludes "The real danger lies in the potential of GMD to disrupt delicate regional balances and to encourage the further development and deployment of nuclear weapons. The United States, China, and Russia have all stepped up their offensive weapons programs since the dissolution of the ABM Treaty. The danger has been succinctly summarized by Mohamed El Baradei, head of the International Atomic Energy Agency: "If we don't stop using double standards, we shall be piled high with an even greater number of nuclear weapons." That would create the exact opposite of the professed objective of global missile defense: security for all who want it" (Evans 2004). This article and several others by Arms Control experts show evidence that the BMDS is causing and will continue to cause WMD proliferation rather than preventing it. **Thus, a non-proliferation analysis is needed for the BMDS PEIS particularly in regard to a genuine no action alternative.**

The BMDS PEIS (page 2-68) provided a justification based on politics rather than on analysis of environmental policy as the rationale for not considering a real "No Action Alternative", namely the canceling of Ballistic Missile Defense Capabilities (and re-engaging in treaty - based arms reductions). On page 2-68 the PEIS states " As suggested to the MDA during the scoping process, one alternative would involve canceling the development of all ballistic missile defense capability development and testing. Such an alternative would rely on diplomacy and military measures to deter missile threats against the U.S. However, this proposed alternative would eliminate the capability to defend the U.S., it's deployed forces, allies or assets for a ballistic missile attack should diplomacy of other deterrents fail. This alternative does not meet the purpose of or need for the proposed action as described in Sections 1.3 and 1.4, respectively; does not meet the direction of the President and the U.S. congress; and therefore will not be analyzed further."
A mainly political justification was also given on BMDS PEIS pages 1-14 for not considering scoping comments showing "concern that the BMDS would create an arms race, especially in space" Š comments showing "opposition to the development of nuclear weapons and concern that missile defense could be a first strike capability for U.S. worldwide military domination". Specifically, the MDA PEIS stated the rationale for excluding these comments is that "Public comments concerning DoD policy, budget and program issues are outside the scope of the Draft BMDS PEIS".
These political justifications used by the MDA are insufficient for excluding these and related issues of non-proliferation from analysis in the BMDS PEIS. A non-proliferation analysis is needed for the BMDS. We all want to be safe from missile attack. The non-proliferation analysis is needed to determine if the BMDS is likely to ultimately increase our security, and maintaining environmental quality or result in an out of control arms race that decreases our security and wreaks wide spread environmental destruction.
Because of the reasonable foreseeability of increased potential for environmental harm due to proliferation and security risks, I strongly recommend that the MDA prepare a detailed Nonproliferation Impact Review for the BMDS PEIS including a Nonproliferation Impact Review EIS for each BMD component and for each BMD site or location. These reviews will determine the scope and need for a MDA high-level program and the alternative that would cause the least environmental harm. If the BMDS is the best alternative for such a program, these review processes will thoroughly assess the potential proliferation, security and environmental harms and ways to mitigate those potential harms. This will mean that proactive plans to protect the environment, public safety and national security will be developed in advance rather than in response to a problem, accident or crisis.

DOE Programmatic EIS Precedent

DC_E0439

The DOE has set an important precedent by conducting a Programmatic EIS, including a Nonproliferation Impact Review (NIR), for its Civilian Nuclear Energy Research and Development and Isotope Production Missions in the United States, including the Role of the Fast Flux Test Facility in December 2000 and for its Stockpile Stewardship and Management in September 1996. Furthermore, Nonproliferation Analyses were conducted in the following DOE EIS or Site-Wide EIS review documents:

· Final Programmatic Environmental Impact Statement for Tritium Supply and Recycling (October 1995); Section 1.5.6 Proposed Nuclear Weapons Nonproliferation Policy Concerning Foreign Research Reactor Spent Nuclear Fuel, Page 1-10.

· Final Environmental Impact Statement on Management of Certain Plutonium Residues and Scrub Alloy Stored at the Rocky Flats Environmental Technology Site(August 1998);

·Final Environmental Impact Statement for the Production of Tritium in a Commercial Light Water Reactor (March 1999).): 1.3.5
Nonproliferation, Page 1-9 and 1-10.

Final Site-Wide Environmental Impact Statement for the Y-12 National Security _ _Complex_ (September 2001): Section 2.2.3 Nonproliferation and National Security, Page 2-7.

Following this precedent, the MDA BMDS, in my opinion, necessitates an equally comprehensive review. Such a Nonproliferation Review Should Include Public Hearing, Scoping and Comment.

25) I highly recommend that the Nonproliferation Impact Review be conducted like the NEPA process that includes public participation in the scoping phase and a draft document circulated for public comment. This open process is critical because intent really is the biggest differentiating factor between defensive and offensive military research. The participation of individual citizens who live near the proposed facility and have personal concerns such as health and property values, as well as representatives from professional and nonprofit groups who specialize in public health, emergency response, sewage treatment, landfills, water, environment, toxicology, science, medicine and arms control may identify unforseen problems, more cost-effective solutions and new ways to open up the process while maintaining necessary security. This scrutiny and public debate can only improve the quality of the decision-making process and will likely result in more confidence in the final decision on the part of those most directly impacted.

26) Which government and university institutions in the State of California will be conducting research to support the BMDS research and development and, if so, please describe their roles, responsibilities and the specific projects they will be involved in? Specifically, will Lawrence Livermore National Laboratory, Lawrence Berkeley National Laboratory, Sandia National Laboratory -- Livermore, or the University of California at Berkeley, Davis or Los Angeles be conducting research or development on the BMD for the MDA or DoD and, if so, what specifically will each that is involved be doing? This is important for people in these areas to know in order to understand, consider and evaluate the possible environmental, health, and safety impacts on their communities.

Thank you for considering these public comments on the BMDS PEIS.

Please confirm that you have received my comments.

Jimmy L. Spearow, Ph.D.

OFFICE OF ENFORCEMENT AND COMPLIANCE ASSURANCE

November 17, 2004

Missile Defense Agency
Ballistic Missile Defense System PEIS
c/o ICF Consulting
9300 Lee Highway
Fairfax, VA 22031

Dear Mr. Lehner:

In accordance with our responsibilities under Section 309 of the Clean Air Act and the National Environmental Policy Act (NEPA), the Environmental Protection Agency (EPA) has reviewed the Missile Defense Agency's (MDA) Ballistic Missile Defense System (BMDS) Draft Programmatic Environmental Impact Statement (DPEIS) (CEQ # 040438).

The DPEIS identifies, evaluates and documents, at the programmatic level, the potential environmental impacts of activities associated with the development, testing, deployment, and planning for the eventual decommissioning of the BMDS. It considers the current technology components, support assets, and programs that make up the proposed BMDS as well as the development and application of new technologies.

EPA commends the efforts that MDA has commenced in producing such a comprehensive and well organized document. We also appreciate your efforts in utilizing the extensive environmental analysis that is available for many of the existing components of the proposed BMDS. Based on our review of the DPEIS, we have rated the document as LO - Lack of Objections (see attached "Summary of EPA Rating System"). Although EPA has no objections to the proposed action, there are a few issues that should be clarified.

DC_F0003

1) General Comments:

a. To assess the impacts of implementing the proposed BMDS, the DPEIS characterized the existing condition of the affected environment in the locations where various BMDS implementation activities are proposed to occur. MDA has determined that activities associated with the proposed BMDS might occur in locations around the world. Therefore, the affected environment has been considered in terms of global biomes, broad ocean areas, and the atmosphere. This has resulted in the DPEIS being very conceptual and general in nature. EPA understands that once potential BMDS locations are determined, more detailed site-specific documents will be prepared. Through the discussions on the "block approach" or the "block development process", the DPEIS has given clear indications of when follow-on NEPA analysis will occur. We agree with this approach. However, while the documents give representative examples of past, current, or proposed locations where proposed activities may occur within each biome, EPA recommends that the EIS discuss the criteria that MDA will use in making future decisions for site-specific locations.

b. The resource areas considered in this analysis are those resources that MDA believes can potentially be affected by implementing the proposed BMDS. EPA agrees that some resource areas are site-specific or local in nature and, therefore, cannot be effectively analyzed in this type of programmatic document and that the potential impacts on these resources are more appropriately discussed in subsequent site-specific documentation tiered from this PEIS. However, EPA recommends that the final document discuss the existence of multiple species habitat conservation planning efforts that are proximate to DoD lands and the potential impacts of debris on marine and aquatic ecosystems.

c. As suggested by CEQ regulations, MDA has taken advantage of the extensive environmental analyses that already exist for many of the existing components of the proposed BMDS by incorporating these materials into the DPEIS by reference. However, some of these documents are greater than 10 years old. The PEIS should confirm the validity of the information in these documents.

2) Perchlorate Comment: Because there have been differing interpretations of the science associated with the impact on human health from low level exposure to perchlorate and in the interest of resolving scientific questions, EPA, the Department of [illegible] artment of Energy, and the National Aeronautics and Space Administration - [illegible] ader Interagency Working Group on Perchlorate led by the Office of S [illegible] ology Policy - have referred scientific issues and EPA's 2002 Draft Health Asses [illegible] rate to the National Academy of Science (NAS) for review. NAS is currently conducting a study to determine the best science and model to use for determining the health impacts and standards for perchlorate. A report on this study is expected to be completed by the end of 2004. EPA recommends that the results of the report be incorporated into the FPEIS.

DC_F0003

We appreciate the opportunity to review this DPEIS. We also look forward to reviewing the FPEIS related to this project. The staff contact for the review is Marthea Rountree and she c [illegible]

Sincerely,

for

Anne Norton Miller
Director
Office of Federal Activities

Enclosure: Summary of Rating Definitions

DC_F0003

SUMMARY OF EPA RATING SYSTEM

Rating the Environmental Impact of the Action

- LO (Lack of Objections) The review has not identified any potential environmental impacts requiring substantive changes to the preferred alternative. The review may have disclosed opportunities for application of mitigation measures that could be accomplished with no more than minor changes to the proposed action.
- EC (Environmental Concerns) The review has identified environmental impacts that should be avoided in order to fully protect the environment. Corrective measures may require changes to the preferred alternative or application of mitigation measures that can reduce the environmental impact.
- EO (Environmental Objections) The review has identified significant environmental impacts that should be avoided in order to adequately protect the environment. Corrective measures may require substantial changes to the preferred alternative or consideration of some other project alternative (including the no action alternative or a new alternative). The basis for environmental objections can include situations:
  1. *Where an action might violate or be inconsistent with achievement or maintenance of a national environmental standard;*
  2. *Where the Federal agency violates its own substantive environmental requirements that relate to EPA's areas of jurisdiction or expertise;*
  3. *Where there is a violation of an EPA policy declaration;*
  4. *Where there are no applicable standards or where applicable standards will not be violated but there is potential for significant environmental degradation that could be corrected by project modification or other feasible alternatives; or*
  5. *Where proceeding with the proposed action would set a precedent for future actions that collectively could result in significant environmental impacts.*
- EU (Environmentally Unsatisfactory) The review has identified adverse environmental impacts that are of sufficient magnitude that EPA believes the proposed action must not proceed as proposed. The basis for an environmentally unsatisfactory determination consists of identification of environmentally objectionable impacts as defined above and one or more of the following conditions:
  1. *The potential violation of or inconsistency with a national environmental standard is substantive and/or will occur on a long-term basis;*
  2. *There are no applicable standards but the severity, duration, or geographical scope of the impacts associated with the proposed action warrant special attention; or*
  3. *The potential environmental impacts resulting from the proposed action are of national importance because of the threat to national environmental resources or to environmental policies.*

Adequacy of the Impact Statement

- Category 1 (Adequate) The draft EIS adequately sets forth the environmental impact(s) of the preferred alternative and those of the alternatives reasonably available to the project or action. No further analysis or data collection is necessary, but the reviewer may suggest the addition of clarifying language or information.
- Category 2 (Insufficient Information) The draft EIS does not contain sufficient information to fully assess environmental impacts that should be avoided in order to fully protect the environment, or the reviewer has identified new reasonably available alternatives that are within the spectrum of alternatives analyzed in the draft EIS, which could reduce the environmental impacts of the proposal. The identified additional information, data, analyses, or discussion should be included in the final EIS.
- Category 3 (Inadequate) The draft EIS does not adequately assess the potentially significant environmental impacts of the proposal, or the reviewer has identified new, reasonably available, alternatives, that are outside of the spectrum of alternatives analyzed in the draft EIS, which should be analyzed in order to reduce the potentially significant environmental impacts. The identified additional information, data, analyses, or discussions are of such a magnitude that they should have full public review at a draft stage. This rating indicates EPA's belief that the draft EIS does not meet the purposes of NEPA and/or the Section 309 review, and thus should be formally revised and made available for public comment in a supplemental or revised draft EIS.

Missile Defense Agency BMDS
P.E.I.S. Comments by Public
United States of America

To whom it may Concern or Cares,

My name is Vikki Jo Kennedy. I am a exiled (Since March 2002) resident of Kodiak Island Alaska. I am currently surviving in Ritchie Co. West Virginia.

I miss Kodiak every day + want to go back Someday.

My Comments on the P.E.I.S. are as follows.

I became personally effected by N.M.D. plans when it was announced on July 13th 2001 that Missile Sites were to be installed by N.M.D. at the Kodiak Launch Complex. And that it was Now a Missile Defense Site. NOT just a Simple "Commercial" Rocket Launch Complex as [illegible] it was at first. This "Site" is only 12 Air miles from the town [illegible] Kodiak where over 3/4 of the Islands Population is located. I was devastated by the announcement buried on Pg. 5 of our Local Lil Paper [illegible] for the 5 or 6 years previous to that announcement I was a Supporter of the K.L.C. + A.A.D.C. I was the tour guide to the Site on many tours. Some of which were for big dignitaries + ranking Military personal. future plans were often discussed in my presence. I sometimes questioned some

DC_F0004

of the plans but was told all was OK and to "NOT worry or be concerned..." "They" Knew what to do and all. I went along. I sometimes scoffed at the small group of Kodiak Citizens (who were all very educated + wise) that were Opposed and skeptical of the KLC. They said it was Sinister etc. The

DC_F0004

②

very first thing to throw-up there red flag was the 23 million dollars the U.S.A.F. gave the A.A.D.C. when the State of Alaska ran Short of funding to complete the State owned K.L.C. they questioned why would the D.O.D. want to put in monies? Well, on July 13th 2001 that all became very apparent to me + many other Kodiak Citizens. I felt So betrayed + used as an Advocate of a program far + beyond what I was told it was to be. I knew I was fooled + Tricked out of my hopefulness that the KLC was A good thing for Kodiak. Now as I sit here writting these Comments 3 years 4 months and 3 days later (But who's Counting - right) I have No Hope this will ever be any good for the Citizens of Kodiak and beyond. I wish it would all just "Go Away" But... We all know that won't happen. Now with the Bush Admin. back in for 4 more Long years God only knows where this will all lead our world too.

So... If you must proceed with this outrageous Program and Launch rockets for military (B.S.) from Kodiak Please Consider my "Wish List" of Concerns + requests OK.

① Take this whole program out to the Aleutian Islands! Thats were all this experimental D.O.D. Stuff should have been put all along. This is all testing. the Kodiak People + Flora + fauna Should not be used this way. Take it West to Adak + Shemya where the D.O.D.

has been set-up doing "there thing" since prior to WW II! Just by the Adak base back from the Native Corp. (It should have never been Sold to them in the first place!) you have all your infrastructure already there too. You Can do lots of experiments out there with lil effects on US citizens if done Correctly.
But.. I'm probably dreaming Big + unrealistic Aye. But... It's better then Crying buckets of tears like I have for the past 3 yrs 4 mos + 3 days + more to come I'm Sure. Just Consider it all please. They Can be a high strike Zone (Target area more then we Can too!)
Since this is a test site for for the G. B. M. D. S. of the M. L. M. D. Please use extream Caution over Safety at All times wherever you do your testing, Please.

① the Planned Rocket Trajectories that go over Kodiak Island + skirt very close to the East Side are just totally [illegible] Native Villages + Bush [illegible] not to mention all the [illegible] Bears!) that live there too.
It is just to damn dangerous to launch over the Island. Period! That Can NOT proceed as planned.

② You have Said in the past year that there are NO longer plans to install Missile Silos on Kodiak. Keep that Plan - No Silos .. Period. You must keep your word true to us citizens. After all its OUR Home + OUR Program too.

③ When you have another Accident like the one on Nov. 09, 2001 where the rocket Blew-up, Tell us the truth right away. Don't lie then tell the truth (forced as it was) 6 mos. later. Maybe if you don't try launching in 40 mph winds with Snow + Rain you might have a better launch window + help the process alot.. just maybe Aye!

④ Dropping Rocket booster Stages Anywhere along the east side (or exterior) of Kodiak Island is totally unacceptable! It is all Critical habitat area for the endangered Steller Sea Lions. There are numerous haul-outs + rookeries all along the Coast of the Kodiak Archipelago. We Commercial fishermen have Severly Shut down from fishing near any of these places So.. You Can't disturb them either! If you kill any off We get the blame, and we will be Shut Completly down from fishing! Please Consider our fate to make a Living OK.

⑤ You do not need to let the AAD[illegible] -up any-more land to use for this progr[illegible] additional 14,000 Acres is our Only area on the Kodiak Road System we (the Citizens) have that is open For Public Use. All the Other land is Private (Native Corps) And 3/4 of the Island is in the Kodiak Island National Wildlife Refuge. Please Do NOT take Control of these lands. No more Land to USE. (the 3,800 Acres you

use now is enough. No more OK. Please.

⑥ Keep it Clean wherever you go to put this all in. Clean up all your toxic Wastes + Garbages. Kodiak Island is one of the most Pristine places left on this planet.. Please Keep it that way. Please.
OUR Close Ocean Waters Are Our Living they must be kept Clean + respected! Rockets + Missiles debrie and fish - just don't Mix! And Last but Not Least ... just be real damn Careful out there. I Love That Island and want to keep it Safe. Please Be Careful.

Thank you for this opportunity to express my opinions. Maybe they will be Considered? I only have true Concerns for my Home + my Country and Planet.

Sincerely,
Vikki Jo Kennedy

[illegible]

LAWYERS ALLIANCE FOR WORLD SECURITY (LAWS)

COMMENTS ON THE BALLISTIC MISSILE DEFENSE SYSTEM DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT

Submitted to the Department of Defense's Missile Defense Agency

By Philip A. Fleming, on behalf of LAWS

The draft Ballistic Missile Defense System (BMDS) Programmatic Environmental Impact Statement (PEIS), dated September 1, 2004, is required by NEPA to provide an objective and through assessment of the effects various missile defense architectures would have on the environment. LAWS submits that it fails in several respects to do this. Instead, it has been developed, organized and shaped to give credibility to the Bush Administration's continued assertions that the only way the United States can be protected from an ICBM attack is with a heavily tiered missile defense system. Consequently, the draft PEIS either does not discuss or dismisses real concerns about harmful negative consequences from developing such a system. In view of this fatal flaw, the draft PEIS is essentially an inadequate attempt to justify decisions that have already been made.

LAWS had assumed, when it submitted comments on October 14, 2004 at the public hearing in Crystal City, Virginia, that some of the PEIS deficiencies could be rem[illegible] by further analysis and substantive changes to the draft. However, [illegible] further study and analysis of the draft PEIS, LAWS has reluctantly concluded that even this flawed document comes so late in BMDS development and testing that it is largely irrelevant. For example, Section 1.2 shows that environmental analyses have already been completed for most components, the notable exceptions being the Aegis BMD and space-based weapons. As we understand it, development and testing of most components are well underway and decisions about initial deployment of GBI's and Aegis BMD ships have been made.

Morever, the spiral development process, which is described on page ES-7 of the PEIS, allows MDA to "consider deployment of a missile defense system that has no specified final architecture and no set of operational requirements." Such a process is apparently intended to preclude any meaningful assessment, and thus far it has

succeeded brilliantly, to the detriment of the public interest, the national defense of the United States, and in frustration of the purpose of requiring careful NEPA analysis of major federal actions.

Another major deficiency of the draft PEIS is that it lacks a genuine "No Action Alternative", even though NEPA explicitly requires that such an alternative serve as a baseline against which to compare the environmental impacts of the other alternatives. LAWS is compelled to conclude that the MDA simply did not consider a "No Action Alternative" seriously. For example, the MDA asserts on page 2-67 that "it would not meet the purpose of or need for the proposed action or the specific direction of the President and the U.S. Congress." Further, footnote 19 on page 1-6 quotes the part of the 1999 Missile Defense Act which declares the policy "to deploy as soon as is technologically possible an effective NMD system." The PEIS also notes on page 1-6 that President Clinton decided in September 2000 not to authorize deployment of an NMD system for reasons including technical uncertainties and unsuccessful flight tests. The PEIS does not concede that even if the technology worked perfectly, the systems being deployed are vulnerable to countermeasures that are easier to build than the long-range missile on which they would be placed, another concern that contributed to President Clinton's decision not to deploy the system the Bush Administration is now rushing to deploy.

In addition, two GAO reports in 2003 and a Union of Concerned Scientists report titled "Technical Realities" released in May, 2004 raise further serious questions about the readiness for deployment of the current NMD components. It seems clear to LAWS that a properly-articulated "No Action Alternative" –which was essentially U.S. policy until 2002 – is vastly preferable until the MDA can persuasively demonstrate that an "effective" NMD is "technologically possible." Recent test results underscore thi[illegible]. The most recent NMD intercept attempt failed on Decemoer 11, 2002, six days before President Bush announced that the U.S. would deploy an ini[illegible] system. This rush to deploy an untested system flies in the f[illegible] the test results so far, and suggests that the independent anal[illegible] that state that it is at least questionable whether an effective NMD system is possible, have been ignored. The policy stakes are far too high, and the $10 billion annual expenditures far too great, to proceed with this global gamble.

LAWS submits that this extraordinary emphasis on missile defense represents misplaced priorities. As President Bush agreed in the pre-election debates with Senator Kerry, the Administration's top non-proliferation priority should be combating the threat of

nuclear terrorism by increasing its programs to keep nuclear warheads and fissile material out of the hands of terrorists. The Bush Administration, however, is giving this problem a fraction of the attention and a fraction of the funding being given to missile defense. Since the technology needed for an effective missile defense system still doesn't exist, LAWS believes that the missile defense system being rushed into deployment in Alaska and at Vandenberg AFB in California is not relevant to the war on terrorism.

I. THE PEIS IS FATALLY FLAWED BECAUSE IT DOES NOT COMPLY WITH NEPA

The width of the range of alternatives that an agency must identify and analyze in an EIS is based on the purpose of, and need for, the agency action. (See 40 C.F.R. Sec. 1502.13, 1502.14.) Therefore, a narrow project purpose and need requires a fewer number of reasonable alternatives than a broad project purpose and need, which may have an infinite number of alternatives. (See NRDC v. Morton, 458 F.2d 827, 835; D.C. Cir. 1972) In addition, the purpose of the proposed action also influences how the "no action" alternative should be presented. When the purpose is narrow, encompassing distinct federal action on a new project, the "no action" alternative must address the environmental effects of the action not going forward, including the effects of any probable outcomes that will occur without the project. (Forty Most Asked Questions, 46 F.R. 18026, at Answer 3.) Alternatively, when the project is broad, encompassing the next phase of federal action in a continuing project, as here, the "no action" alternative must consider the effects of "no change" from the present course of action. (See also American Rivers v. Federal Energy Regulatory Commission, 201 F. 3d 1186, 1201; 9th Cir. 1999).

Here, MDA's interpretation of the proposed project purpose and need is internally inconsistent - in one case narrow, in the other broad. The MDA chooses its alternatives based on the narrow purpose of developing an integrated, multi-layered BMDS while its "no action" alternative allowing for continued research and testing of a non-integrated BMDS, implying that the project supports the general purpose of protecting the United States from foreign missile attacks through any means necessary. (PEIS at pp. 1-1 to 1-8, describing the general history of the government's ongoing development of ballistic missile defense programs.) Consequently, in the PEIS, the MDA sets out two internally contradictory positions On the one hand, the MDA narrows the purpose of the proposed action, and thus the spectrum of alternatives to be considered, to the creation of a singular, integrated, multi-layered BMDS that is not part of a continuing program to protect the U.S. from ballistic missile attacks. On the other

hand, the agency relies on the long history of the U.S.'s missile defense actions to frame its "no action" alternative as a "no change" in an ongoing project with the broad purpose of protecting the U.S. from ballistic missile attacks. On either ground, the PEIS fails to meet the NEPA test – that it interprets its purpose too narrowly in order to develop a very narrow spectrum of alternatives, or that it interprets the purpose too broadly in order to assert a "no action" alternative that allows for continuing, non-integrated action – but not both.

In determining whether the alternatives analyzed within an EIS are adequate, courts have determined that the range of alternatives an agency must consider, although not "self-defining," is 'bounded by some notion of feasibility." (Vermont Yankee Nuclear Power Corp. v. NRDC, 435 U.S. 519, 551 (1978). Accordingly, the alternatives examined by an agency must include only those that are reasonable and feasible – i.e., that are "meaningly possible". However, reasonableness is determined through a fact-specific examination of each proposed project because "what constitutes a reasonable range of alternatives depends upon the nature of the proposal and the facts in each case.

A flaw in the PEIS is that the range of alternatives considered by the MDA is not adequate, because the agency unreasonably narrowed the range of alternatives to be examined by narrowly interpreting the purpose of the proposed action as the development of a multi-layered ballistic missile defense system. While courts typically afford agencies some discretion in defining the purpose and need of a proposed project, that discretion is limited by the reasonableness of the agency-defined purpose and need. It is also clear that an agency may not characterize its proposed action purpose so narrowly as to avoid its NEPA obligations. (See Friends of Southeast's Future v. Morrison, 153 F.3d 1059, 1066; 9th Cir. 1998, and Simmons v. US Army Corps of Engineers, 120 F.3d 664, 669-670; 7th Cir. 1997. It seems to LAWS that that is exactly what the MDA has done here. We doubt that a reviewing court would condone it, or find that when an agency varies its interpretation in order to avoid its NEPA responsibilities, the PEIS can be found to meet the NEPA standard.

In this connection, the spectrum of alternatives to be considered must be broader than those considered by the MDA. (See Morton, 458 F.2d at 837) Accordingly, a court could find that consistent with its obligations under NEPA that the MDA should have considered as an alternative the Theater Missile Defense System which has already been developed and, therefore, would not require excessive resources to implement. The MDA should also have considered, and included in the PEIS, alternatives that offer a less than complete solution to the problem. To the extent that it hasn't, the MDA should also have analyzed the BMDS platforms for each component and/or defense environment separately.

DC_F0005

6 of 7

Other options include an analysis of alternatives that include both weapon and non-weapon components; such as integration of land and sea-based platforms only with increased diplom[illegible] efforts. As the Court said in Morton, an agency cannot
restrict its alternatives because it is not part of its jurisdiction. Since the BMDS is part of a broader purpose of protecting the U.S., the MDA should have fulfilled its NEPA obligations by analyzing a much broader spectrum of alternatives to achieve this purpose.

As pointed out above, instead of crafting the PEIS to justify decisions that have already been made, the MDA should have included a genuine "No Action Alternative", as required under NEPA. Such an alternative could have been "Cancel Development of Ballistic Missile Defense Capabilities" because it does not meet the purpose of or need for the proposed action. It is acceptable under NEPA to evaluate and reject a No Action Alternative because it doesn't meet the purpose of a program, but the environmental impacts of that alternative must be considered as a baseline against which to compare the environmental impacts of the other alternatives. This the MDA has not done. For example, the PEIS projects 515 BMDS launches over the next decade. The sheer volume of this many launches dwarfs the number of projected government and commercial launches over the same period, and the volume of solid rocket propellant involved will generate large quantities of hydrogen chloride, which reacts in the atmosphere to create acid rain. The PEIS should provide more detailed estimates of perchlorate waste likely to be generated by system development, testing, deployment, maintenance, and decommissioning, and acknowldge the potential impacts of such exposure.

II The draft PEIS fails to analyze what would be required to develop a space-based test bed, dismissing the suggestion as "too speculative." But that is precisely what the PEIS is supposed to – to examine the environmental effects of the proposed action. Accordingly, the draft PEIS is flawed for not looking at the effect of space-based interceptors in lieu of terrestrial-based ones - it simply suggests that future studies may be required. This dismissive attitude toward NEPA would not survive judicial scrutmy. Nor would the back-of-the-envelope dismissal of debris, orbital and otherwise. Frequently the PEIS posits that such debris poses a small risk, and downgrades the threat – which would come as a great surprise to our partners in the International Space Station. LAWS' adopts and incorporates here by reference the compelling exposition of the dangers from space debris set out in the October 18, 2004 testimony of Theresa Hitchens, Vice President and Director of Space Security of the Center for Defense Information. This is a dramatically fatal flaw in the PEIS; one that ought not be swept under the NEPA rug.

III Some additional detailed comments and suggestions, in addition

DC_F0005

7 of 7

to those raised by others who testified and submitted statements at the four quasi-hearings the MDA held in October, include:

(1) In order to evaluate the risks from launch failures, the PEIS should give qualitative information on the reliabilities of the boosters to be used to launch targets for BMDS tests.
(2) The draft PEIS contains no discussion of INF Treaty restrictions on long-range air-launched and sea-launched targets, or START Treaty restrictions on sea-launched targets. Accordingly, the PEIS should examine in detail treaty compliance of various BMDS tests.
(3) The PEIS discussion of cumulative impacts in Sec. 4.1.4 and Appendix I contains no details about the location, schedule, and specific missiles to be used for the estimated 515 launches from 2004 to 2014. They are essential.
(4) The PEIS should indicate when an environmental analysis of the Aegis BMD system will be done. The earlier EIS relied upon at page D-15 is contains misleading information.
(5) The PEIS should review the testing of future laser weapons systems and specify testing plans for other high-power laser laser weapons and other energy-directed weapons. It does not.
(6) If interceptors armed with nuclear weapons are being considered or missile defenses, as some reports indicate, the PEIS should indicate what research and development work is being planned for such weapons as part of the Advanced Systems in Appendix F.

Please acknowledge that you have received these comments.

Dear Project Leader:

Thank you for the opportunity to review the Missile Defense Agency Ballistic Missile Defense System Programmatic Environmental Impact Statement. On behalf of the National Oceanic and Atmospheric Administration (NOAA), provided here are comments developed by NOAA's National Marine Fisheries Service (NOAA Fisheries). NOAA's responsibilities include conservation of resources under the Magnuson-Stevens Act Essential Fish Habitat provisions, Endangered Species Act, and Marine Mammal Conservation Act.

Should you have questions and when you are ready to consult further with NOAA regarding requirements under the above statutes, please contact the NOAA Fisheries Southwest Regional Office at 562-980-4000.

Sincerely,

For Ramona Schreiber
Susan A. Kennedy
Acting NEPA Coordinator

DC_F0006

NOAA Fisheries Southwest Region's comments for inclusion in a NOAA response for the Missile Defense Agency's proposed Ballistic Missile Defense System

The Southwest Region, National Marine Fisheries Service (SWR) has reviewed the September 1, 2004, draft Programmatic Environmental Impact Statement (draft PEIS) for the Missile Defense Agency's proposed Ballistic Missile Defense System (BMDS). The purpose of the proposed action is for the Missile Defense Agency to incrementally develop and field a BMDS that layers defenses to intercept ballistic missiles of all ranges in all phases of flight. The BMDS is proposed to be a layered system of defensive weapons that have the potential to impact particular trust resources of NOAA during activities associated with the development, testing, deployment, and planning for decommissioning of the BMDS. This memo letter the SWR's comments on the proposed action under purview of the Essential Fish Habitat (EFH) provisions in the Magnuson-Stevens Fishery Conservation and Management Act (16 U.S. C. 1855, *et. seq.*), and protected resource provisions in the Marine Mammal Protection Act (16 U.S.C. 1361 *et. seq.*), and the Endangered Species Act (16 U.S.C. 1531 *et. seq.*).

Essential Fish Habitat Conservation Recommendations

Pursuant to 16 U.S.C. § 1855(b)(2) of the Magnuson-Stevens Act, Federal agencies are required to consult with the Secretary of Commerce (delegated to NOAA Fisheries) with respect to "any action authorized, funded, or undertaken, or proposed to be authorized, funded, or undertaken, by such agency that may adversely affect any essential fish habitat identified under this Act." In addition, the Magnuson-Stevens Act also requires the Secretary of Commerce recommend to the federal action agency particular measures that can be taken by such agency to conserve fish habitat (16 U.S.C. § 1855(b)(4)(A).

This consultation involves the EFH of anadromous and marine species managed by the Pacific Regional Fishery Management Councils within the Exclusive Economic Zone of the United States for the Pacific Salmon Fishery Management Plan (FMP), the Coastal Pelagic Species FMP, the Pacific Groundfish FMP, and the Highly Migratory Species FMP. These species utilize various habitats that include riverine, estuarine, and marine systems and these habitats may be adversely affected by some of the activities associated with the development, testing, deployment and planning for decommissioning of the BMDS. Primarily, the agency is concerned about potential release of hazardous materials (e.g., chemicals, propellants, propellant by-products, launch emissions) that potentially could be released directly and indirectly to the habitat types listed above during various phases of the BMDS. In order to minimize these potential impacts, the SWR advises the following:

1. NOAA Fisheries recommends that the Missile Defense Agency be responsible for handling and disposing of all hazardous materials or hazardous wastes in all phases of the proposed action in accordance with applicable Federal, state, and local laws, utilizing best management practices at all life cycle activities of the proposed action and through appropriate project planning and design measures including appropriate spill prevention, control and contingency plans (e.g., Oil Discharge Prevention and Contingency Plan, Storm Water Pollution Prevention Plan) for each site.

DC_F0006

Endangered Species Act

Based on the information provided in the draft PEIS, NOAA Fisheries recommends that the Missile Defense Agency consult with the appropriate NOAA Fisheries Regional Office to determine if listed species under the Endangered Species Act (ESA) of 1973 as amended (16.U.S.C. 1531 *et. seq.*) may be affected by the proposed project. If it is determined that this project may affect a listed or proposed species, the Missile Defense Agency should request initiation of consultation with NOAA Fisheries pursuant to section 7 of the ESA.

Marine Mammal Protection Act

Whales, dolphins, seals, and sea lions are protected under the Marine Mammal Protection Act (MMPA). Under the MMPA, "take" of a small number of marine mammals is permitted by NOAA Fisheries under an Incidental Harassment Authorization (IHA) when the specified activity is incidental, but not intentional. "Take" is defined as harassing, hunting, capturing, or killing, or attempting to harass, hunt, capture, or kill any marine mammal. "Harassment" is defined as any act of pursuit, torment, or annoyance which has the potential to injure a marine mammal in the wild, or has the potential to disturb a marine mammal in the wild by causing disruption of behavioral patterns, including, but not limited to, migration, breathing, nursing, breeding, feeding, or sheltering. Based on the information included in the draft PEIS, the proposed project may cause take of marine mammals under the jurisdiction of NOAA Fisheries. NOAA Fisheries recommends that the Missile Defense Agency consult with the appropriate NOAA Fisheries Regional Office when conducting the site-specific analyses for potential impacts to marine mammals.

Missile Defense Agency BMDS PEIS
c/o ICF Consulting
9300 Lee Highway
Fairfax, VA 22031

Dear Friends,

Women's International League for Peace and Freedom (WILPF) submits the following initial comment on the current draft Programmatic Environmental Impact Statement of the Missile Defense Agency.

WILPF is a ninety year old non-governmental organization that has worked tirelessly since its inception to put an end to war. WILPF has supported the development of international institutions and international law, and non-violent methods of conflict resolution that together can facilitate the co-existence of diverse nations and peoples on this planet.

We hope the comments of ourselves, and of others who oppose the militarization of space, will be considered seriously, and that both environmental concerns and concerns for the future of our human race will lead to suspension of this ill-advised and destabilizing missile defense program.

The MDA draft PEIS seeks to answer to detrimental environmental effects of three alternative development plans for Ballistic Missile Defense. We have found the answers disturbingly incomplete. We have also carefully considered all three alternatives presented and have concluded that it would be dangerous – and indeed disastrous -- for the future of our nation to proceed with any of them. It is impossible to comment on all the details in the 701 page document in this short space, but we expect to submit several supplementary comment papers on a few of the many issues of deep concern to us.

First, we are convinced that Alternative 2, which includes development of space based interceptors, is completely unacceptable. We will submit additional comments on both the issue of debris from experiments with space based weapons and on the development of laser weapons. We have other concerns re Alternative 2 that you will perhaps argue are beyond the scope of this PEIS, but that makes them no less important. One is the creation of orbiting debris in space which will remain there

DC_PHW0008

as a threat to future space exploration. The second of these is that space based laser interceptors will be a first step toward the more ambitious program of space weaponization already developed by the Pentagon and the Space Command, and presented in detail in the November, 2003 *U.S. Air Force Transformation Flight Plan*. This is a direction in which no civilized nation should proceed!

We believe that Alternative 1, which does not include space based weapons, and Alternative 3, which is unclear on this point, are also unacceptable, even from a solely environmental viewpoint. We are concerned about the adverse effects in all of the resource areas discussed in the MDA PEIS including hazardous waste, legal restraints, decommissioning of the weapons systems, destruction of the ozone layer, global warming and rocket fuel pollution of our water and river systems. We are preparing supplemental comments on at least some of these concerns.

We also wonder why this expensive and almost certainly unachievable missile defense program has been developed in the first place. It does not answer to probable threats to our national security in the present or in the coming decade. It will do nothing to prevent terrorist attacks, and there is now no hostile country or group with the capability of firing inter-continental ballistic missiles at the United States. Missile defense seems rather to be preparation for future confrontation with the only two countries really capable of threatening our current military domination or challenging us with nuclear attack. Neither of them – China or Russia – is currently an enemy, but this aggressive program may well push them into organizing allies and forces against our own threat of global – and planetary -- domination.

With this in mind, we will submit an additional comment on what we consider to be the only feasible alternative approach to protection of our land and peoples from intercontinental ballistic missiles, from the ravages of nuclear, biological or chemical warfare – or, indeed, from either attacks by small bands of terrorists or from what we have come to call "conventional warfare" (e.g. our own recent "shock and awe" attack on Baghdad).

This Alternative 4 would include a return to the United Nations disarmament treaty process (which the current Administration is regrettably blocking), and assumption of a lead role in the continual development of enforceable and universally applied international law consistent with both the UN Charter and the Universal Declaration of Human Rights. The United States would re-enter that process as the most powerful and most militarized nation in the world and would have no substantial military rivals. This is a rare and critical moment in history and the choice is ours: the United States can lead the way toward a world freed from war with sustainable development and human rights for all – or this nation can drag the human race backward with it into a world ruled by war, military domination and the threat (or use) of weapons more powerful than any known before.

For us in the WILPF there is no question about which route is preferable. We are convinced that continuing with any of these three BMD programs will make the step-by-step process of nuclear disarmament impossible, make war on earth and in space inevitable, and seriously threaten human existence and the entire fragile web of life on our unique and precious planet. We urge all those in the Pentagon, the Missile Defense Agency and in the aerospace corporations to join us in choosing life over death and step-by-step peace building over further destruction of this planet and its fragile web of life.

Sincerely,

Sandy Silver

Missile Defense Agency
BMDS PEIS
c/o ICF Consulting
1300 Lee Highway
Fairfax, Va 22031

Gentlemen:

I urge that the employment of the untested missile defense system be halted until realistic testing can be completed.

As you know, the Missile Defense Agency is required by law to prepare a Programmatic Environmental Impact Statement to assess the missile defense system's environmental consequences, including national security concerns. The Bush Administration's intention of deploying the system without regard to the PEIS process, and without conducting realistic tests will result in its being ineffective against real attack.

According to expert analysis by the Union of Concerned Scientists, such tests are necessary to determine whether the system will work. It states that the system should be tested at full operational speeds, using components identical to those in the final version of the system, and should be tested against countermeasures such as decoys that could fool or overwhelm the defense. No tests have yet been conducted under these conditions.

In addition, the ADministration's missile defense system lacks a key component: the X-band radar intended to track incoming warheads and help guide the interceptors to their targets.

The present head of the Pentagon's testing office wrote in January 2004 that there were not enough test data to assess the effectiveness of the system planned for deployment. His predecessor recently wrote that the "system to be deployed in 2004 will not have the major elements needed to be operationally effective and would appear to be just for show." The statements of both heads of the testing office were according to reliable information obtained by the Union of Concerned Scientists.

The untested missile defense system has the potential to undermine space security, and is nothing more than a wasteful, and potentially dangerous, political charade, according to the Union of Concerned Scientists.

I respectfully request that you inform me as to what steps you intend to take in this matter in order that I may inform the head office of the Union of Concerned Scientists in Cambridge, Massachusetts.

Sincerely,

Louis S. Campbell
Member, Union of Concerned Scientists

Re. NO ACTION Alternative is the only viable option

Dear Sir/Ma'am

In reviewing the three alternatives regarding a Draft Programmatic Environmental Impact Statement for the proposed Ballistic Missile Defense System, we find both Alternative 1 and Alternative 2 to be unacceptable in that if either were implemented, either would generate a new arms race in space, resulting in unimaginable environmental damage, even just from testing of its components, and possible accidents or errors

The NO ACTION alternative is the only acceptable option, but one in which there would be NO FURTHER RESEARCH OR DEVELOPMENT of "Missile Defense" systems or "Space Based Weapons."

The proposed Ballistic Missile Defense System (BMDS) would have unacceptable toxic and damaging environmental impacts at all stages of the project, particularly testing and deployment. Environmental consequences, if the system is ever used, could be severe in locations where impact would occur, and possibly impact neutral countries that were not a part of the nations which were at conflict.

In our view, our government has not made a convincing case that the BMDS is necessary or desirable. We firmly believe there is no credible enemy missile threat that would justify expending the huge cost (scarce materials, energy supplies, brain power, etc.) to create a complex system that in itself is causing environmental damage, and which diverts limited resources away from desperately needed infrastructure building or repair, or provision for a variety of human needs. U.S. National Security will be enhanced if those funds are directed to environmental cleanup, a safe energy system that would disconnect our economy from oil dependency, a universal health care plan, public education, jobs, affordable housing, public transportation and the like

So our basic conclusion would be that a NO ACTION alternative, that
NO ACTION, cutting off all funding for any further development of B ems of it.

The recent election has given this administration a vote of confidence for its "moral leadership." Those who plan military activities should take this moral mandate to heart, and plan a truly DEFENSIVE military program.

The BMDS is part of a political mindset whose ultimate goal is U.S. supremacy by military might. This is not a moral position or policy. WILPF and the majority of U.S. citizens strongly oppose this goal. The MORAL position would be to have policies that generate cooperation and

co-existence of all peoples. Such a policy of co-existence and cooperation would not destroy our environment by adding further to the ozone destruction with unneeded and resource-wasteful launches (test or actual firings) of a BMDS

The BMDS for which these comments are solicited would create a terrible arms race in space. Other countries may not be as careful as the U.S. in trying not to pollute the environment

Further testing and deployment of this system, whether U.S. or other countries that will be forced to compete with the U.S., would

1) cause further releases of toxic rocket exhaust that is already damaging the ozone. Present rocket launches must be reduced because of this perchlorate and other toxic releases

2) pave the way for use of nuclear reactors in space, a very dangerous precedent, with potentially catastrophic consequences. There have already been accidents of space vehicles whose instruments were powered by RTG's, spreading radiation in our atmosphere and also where crashes to earth have polluted the soil. The same risks, only more severe, are inherent in launching nuclear reactors in space. This is an unacceptable risk

3) greatly expand the amount of space debris, causing additional hazards for existing communications satellites and interference for future scientific space exploration

We strongly recommend that a United Nations oversight board be constituted that would review all space related activity... worldwide... with advisory AND enforcement capacity. Regulations must be set to curb extravagant uses of space, risky and unwise launches, reduce duplication of space exploration, and to encourage information sharing between countries. This oversight board could help minimize environmental pollution. Knowledge learned could be shared, to reduce the stress on the environment

In summary, we strongly advocate a No Action Alternative, and further request that the PEIS should be re-written to take into consideration the issues raised in this comment

These comments are submitted on behalf of the members of the Tucson Branch of the Women's International League for Peace and Freedom

Sincerely,

Patricia Birnie

Patricia Birnie, Legislative Chair

To: Missile Defense Agency November 12, 2004

Concerning: Environmental impact of Space based Missile Defense Systems

I am writing to express my concerns about the environmental impact of the Ballistic Missile Defense System.

At this time we are discovering just how polluting our use of fossil fuels is to our environment: creating global warming with it's multitude of known and unknown effects, and directly affecting the health of humans, as shown in the ever increasing numbers of people with asthma, especially in children.

Now our government plans to deploy even more satellites and space weapons, with more rocket fuel polluting our upper atmosphere. Even if we didn't use the space weapons (which is unlikely), we will change the earth's atmosphere in ways we won't know until it's too late, just by putting it in place and testing. This will affect not only our own country and people, but the whole world.

The cost of this unproven system will deny citizens their needs on earth, including measures to clean up and protect the environment. The expense of this system far outweighs it's (lack of) necessity. If we need money for security, the money should be spent on defense against the new reality of terrorism, which uses underground, low technology violence. Expensive space based defense answers the new violence with cold war thinking and will not protect us. Rather, the use of space based weapons would ultimately be detrimental to all through degradation of the atmosphere and our planet. Such degradation could also make scientific space exploration more difficult because of space "junk".

For all these reasons, I support ending all work on the Missile Defense system. None of the alternatives presented in your Draft Programmatic Environmental Impact Statement includes ending the program. Therefore, I call on you to rewrite and resubmit the PEIS for public comment, including another alternative: ending the Missile Defense System.

The No-Action Alternative

Dear Friends,

This is the second comment submitted by Women's International League for Peace and Freedom on the Missile Defense Agency draft *Programmatic Environmental Impact Statement.* This comment is submitted by the WILPF DISARM: Dismantle the War Economy committee. We are proposing a different text for Alternative 3, or it can be considered as Alternative 4.

The existing text for Alternative 3 is not a NO ACTION alternative. The MDA itself rejects it as an inadequate version of the first two alternatives presented. The present Alternative 3 would include all of the components in Alternatives 1 and 2 and apparently also space-based weapons, but MDA would develop them individually rather than as an integrated system.

WILPF believes a genuine alternative should be presented against which to compare the other two. A summary of proposed Alternative 4 is given here, followed by comments on the environmental impact and wider implications of this approach.

Alternative 4 (revised Alternative 3)

1) Beginning in January 2005 **the current Ballistic Missile Defense Program (BMD) would be suspended immediately and in entirety**, or a moratorium on deployment, research and development would be declared while a thorough investigation of the program occurs.

Congress, the Administration, auditors, scientists, aerospace engineers and the general public would participate in a thorough reconsideration of the costs, workability and desirability of this program in all its aspects.

2) The President of the United States would at the same time announce his intent to **return to the United Nations disarmament treaty process** which the United States has been blocking during the past four years. Of first importance would be reaffirmation of the *Nuclear Weapons Non-Proliferation Treaty* (NPT) and of our intent to keep the 13 promises made at the close of the NPT Treaty Review in 2000.

In the past four years the present Administration has broken all but two of these promises. Continued pursuit of the BMD treaty will almost certainly result in the collapse of the NPT and in further nuclear weapons proliferation. This would be a tragic loss. The NPT has over the past 34 years resulted in the reduction of nations with nuclear weapons. Seventeen nations have given up their nuclear weapons. By 2002, with Cuba's accession, 188 nations were subject to the NPT's provisions. Only Israel, India and Pakistan, all with nuclear weapons programs, remained outside the treaty. In January 2003 the Democratic Republic of North Korea withdrew from the treaty, arguably in reaction to new, more aggressive U.S. nuclear policies including the BMD program, and our failure to help it solve its energy problems. **The aggressive pursuit of Missile Defense during the past four years and initial deployment, though its components are at present unworkable, is not consistent with support of the NPT.**

The President would, as a matter of greatest urgency, show U.S. support of the NPT in concrete ways. An announcement of the **dismantling of the BMD program** or a moratorium on its development would be a significant first step. A second would be to declare an **end to research and development of new classes of nuclear weapons,** in violation of Article Six of the NPT. Continuance with the BMD program almost certainly ensures a new nuclear arms race, and new era of either cold or hot war.

3) The President would at the same time work with our allies and the United Nations to **bring India, Pakistan, Israel and North Korea into the NPT.** The U.S. would support vigorous international inspections of all known and suspected nuclear weapons programs, including its own, in both nuclear and non-nuclear countries. The U.S. would also assist in the development and application of more adequate treaty enforcement mechanisms. The best alternative to the environmentally unfriendly Missile Defense, to a new nuclear arms race, and to the threat of global war is to move step-by-step toward nuclear weapons abolition as already agreed by the U.S. under the NPT.

4) The President would at the same time **declare an end to the Pre-emptive War Doctrine** put forth in the Nuclear Posture Review and the National Security Strategy, both issued in 2002. This doctrine, coupled with the development of BMD, is viewed as threatening by most non-nuclear nations and by some of the current nuclear weapons powers.

5) The President would at the same time declare the United States' intent to participate in good faith in all other treaties relevant to the control and eventual abolition of nuclear weapons.

Immediate steps would include reaffirmation of the intent to **ratify the Comprehensive Nuclear Test Ban Treaty (CTBT)** which the present Administration has declared against U.S. national interests, even though it was signed with intent to ratify by a previous President. The President should also announce a complete moratorium on preparations for nuclear weapons testing while pushing for Senate ratification of the CTBT. The U.S. should support the new treaty on fissile materials which it has recently blocked after years of work towards it. Many additional steps could be considered and undertaken.

6) The President would at the same time reaffirm the U.S.'s continued support for other disarmament treaties previously ratified which we have been blocking or undermining during the past four years. This would include enforcement of **the 1967 Treaty on the Peaceful Uses of Space** and cooperation with Canada and other nations to expand it to include a ban on weaponization of space and rules for regulation of corporate development in space.

This reaffirmation would include **the Bio-weapons treaty,** for which the current Administration has rejected international monitoring and inspection. It would include the treaty on Chemical weapons with which there is currently evidence of U.S. compliance. Another argument put forth by the MDA for the BMD is the need to counter missiles carrying biological or chemical warfare agents. A better defense against these weapons of mass destruction would be the dismantling of all chemical and bio-weapons programs, and international monitoring and inspection to ensure continuing compliance with the existing Bio-weapons treaty. In addition, the United States should again contribute to development of international controls on, and eventual elimination of, inter-continental ballistic missiles.

7) The President would, at the same time or immediately after taking the above urgent steps, **reaffirm the entire UN treaty process** designed to promote sustainable economic and social development, human rights and democracy on a global scale. The United States should be a leader in the ratification of treaties ensuring human rights and sustainable development, rather than one of the laggards. Progress in these areas will remove many of the factors contributing to the non-state violence employed by relatively poorly armed rebels against powerful governments or formidable military forces which they perceive to be exploiting and/or oppressing them and their ethnic, religious or ideological groups.

Environmental impact: The detrimental environmental effects of this approach will be far less than those resulting from testing or utilizing the integrated Missile Defense System as outlined in Alternatives One, Two or Three. If the BMD system is suspended, the major detrimental effects would occur in the dismantling process. Even this process, however, would have far less impact than would dismantling the system after three or more decades of development. It would also have far less detrimental environmental impact than if BMD development triggers a new nuclear arms race or results in the actual use of nuclear, biological or chemical weapons. Indeed, laying down the BMD program would release funds and scientific expertise that could be turned to resolving he other great environmental problems now threatening the planet and its peoples.

Proponents of Ballistic Missile Defense should not be concerned that dismantling the BMD system would leave the United States more vulnerable to attack. The United States would be re-entering the United Nations treaty process in a position of unsurpassed military strength. The U.S. already possesses the most powerful military system in the history of the world, arguably more powerful than those of all other nation states combined. If a strong military gives security, then the United States should be the most secure nation on earth.

When the United States begins to lead the way in the UN disarmament treaty process it will not be engaging in unilateral disarmament, but rather joining other nations in a step-by-step

process away from the horrors of war. The U.S. would not re-enter the treaty process in any greater danger than it can expect during the next decade while seeking to develop a Ballistic Missile Defense system. For that system – even if it eventually "works"--does nothing to protect against non-state violence, and the U.S. has no enemies at present among the nations capable of striking its territories with ICBMs. The continued development of this exorbitantly expensive BMD system that may never work raises tensions, creates enemies and makes both nuclear and conventional war on a global scale more, rather than less, likely to occur.

The United States would not put itself in any greater danger than at present, but would shift emphasis, choosing to work for the continuance of human life on earth, with liberty and justice for all, rather than blatantly risking humanity's final destruction in its search for global and planetary domination. There would be many challenges and difficulties along the way, but the choice is between the way of life and the way of death and destruction.

Let us choose the way of life.

In peace,

Space-Based Interceptors

Dear Friends,

This is the third comment submitted by Women's International League for Peace and Freedom (WILPF) to the Missile Defense Agency regarding its draft Programmatic Environmental Impact Statement (PEIS). This comment is submitted by the WILPF *DISARM: Dismantle the War Economy Campaign.*

We are commenting briefly on the unacceptability, from an environmental standpoint, of space-based interceptors as proposed in both ALTERNATIVE 2 and ALTERNATIVE 3 (the so called NO ACTION ALTERNATIVE) in the draft PEIS. We see serious environmental threats from orbital debris, from development and testing of laser and kinetic kill weapons, from the possible use of nuclear power in space, and from the further development of weapons in space technology that can also be used against satellites and targets on earth.

Orbital debris: Testing and deployment of space-based interceptors can significantly increase space debris, endangering other objects in space, in the air and on land. We agree with the commentators from the Center for Defense Information that the PEIS does not answer sufficiently to these problems and dangers. We suspect the detrimental environmental effects are great enough in themselves to warrant cancellation of this portion of the program.

Laser and kinetic kill weapons: The PEIS does not really deal with the detrimental environmental effects that will result from the process of developing, testing and deploying laser and kinetic kill weapons. Yet, these weapons are integral to the entire program. We understand there are still many problems to be solved if these science fiction fantasies are to be translated into reality. These problems and the dangers posed to the environment should be included in the PEIS. We suspect that they are great enough to warrant cancellation of the space weapons program.

Nuclear power in space: It is posited that the space platforms may include as many as twenty (or even more) satellites in a constellation, kept in space for years with their own power system. What is that power system? We know that nuclear power has been considered, which we believe would carry us in a very dangerous direction. Possible power systems and their negative effects on the environment must also be realistically examined. We believe nuclear power in space would be an unacceptable alternative.

Weapons in space: The PEIS considers, albeit inadequately, only the question of space based interceptors as part of the missile defense program. It is clear, however, from documents like the *Air Force Transformation Flight Plan,* that the Pentagon intends to use this same laser and kinetic kill technology for both offensive and defensive attacks on satellites of other nations and for offensive and defensive destruction of targets on earth. Other weapons not suitable for missile interception, like the so-called "Rods from God," are also being planned. All of this is in clear violation of the intent of the 1967 treaty on the Peaceful Uses of Space, and it is a direction in which no civilized nation should proceed.

Why is our military moving to weaponize Space at a time when there is more hope than ever before in history of realizing the visions set forth in the American Constitution, the European Union, the United Nations Charter and the Universal Declaration of Human Rights? Other nations do not welcome United States plans for unassailable superiority in space and for global and planetary domination. We are actually forcing other governments - like those in the European Union, China, India, Russia and Brazil – to cut back on their social programs in order to develop their own military space programs in self-defense. Why must we threaten all the cooperative international institutions that nations have built together, with so much difficulty, over the past sixty years and force the world's peoples back on the road to global war?

We are women with a deep love for this planet and its peoples. We know well the horrors of war and we know that women and children suffer those horrors in full measure. It is for the sake of our sisters and their children around the globe, and for the sake of men as well, that our organization has worked for ninety years to develop alternatives to war. We have striven tirelessly for international institutions like the United Nations and the World Court, for international law, for conflict management and prevention, and for the meeting of basic human needs. We continue to have faith – based upon experience --that the nations and peoples on this planet, working together, can develop a world free of war with liberty and justice for all. We do not want our own nation, which has in the past contributed so much to the growth of democracy and human rights in the world, to now lead our human race into the untold horrors of Armageddon.

We urge abandonment of concepts like space weapons and war in space as well as suspension of the entire Missile Defense System. The immediate threats to the environment are reason enough to lay down the program. The threats to the planet and its peoples, if the war fighters ever get the battles for which they plan, are beyond contemplation.

Hazardous Waste

Dear Friends,

This is the fourth comment by Women's International League for Peace and Freedom (WILPF) on the Missile Defense Agency (MDA) Programmatic Environmental Impact Statement (PEIS). It is submitted by members of the DISARM: Dismantle the War Economy Campaign. It concerns the detrimental environmental impact of hazardous waste from various aspects of the Ballistic Missile Defense (BMD) program.

Acid rain: The MDA itself notes in the PEIS the possibility of acid rain caused by rocket launches: *In biomes where rain is a frequent occurrence, launches with solid boosters have an increased likelihood of contributing to acid rain, thereby increasing the amount of HCl deposited in regional surface waters. In areas with low velocity of surface and groundwater movement and relatively shallow ground water table it is possible that deposition of acidic water may impact water resources. The potential for and extent of impact would need to be examined in site-specific environmental analysis. (item 4-60)*

The MDA knows at present from where ground based interceptors will be launched, and site specific studies should be absolutely required in the PEIS.

Ammonium Perchlorate: This toxic rocket fuel additive is already a dangerous pollutant in California and the southwest. Across the United States some 20,000,000 people already have their drinking water contaminated by perchlorate. Further poisoning of the ground water and rivers from perchlorate is simply unacceptable. We must not further endanger the health and lives of people the BMD system claims to protect. We need to find ways to preserve the health of our people and our environmental systems, and not contribute further to their destruction.

Other hazardous waste: The MDA promises to dispose properly of hazardous materials from activation of laser weapons, such as chemical simulants, laser chemicals, asbestos, lead based paint, polychlorinated biphenyls, radon gas. However past experience tells us that military test sites are frequently left polluted and with ecosystems and surrounding communities endangered.

When it comes time for decommissioning the military often finds it does not have the technology, or the funds required, to clean up damaged sites. This has certainly been true of other complex systems, like those involving chemical and nuclear weapons. In those cases there is still uncertainty about how to safely destroy or store decommissioned weapons and the associated toxic wastes. MDA needs to address these questions satisfactorily in advance. We suspect they are not addressed because costs involved would be prohibitive and in some cases the technology for disposal does not exist.

Hazards of use: Completely missing in this PEIS is an analysis of the hazards of use if the BMD system is ever employed. This is not a benign system, and possible hazards should be investigated. What would be the effect of a successful intercept over the Pacific Ocean or seconds after firing by another nation? What would be the extent of nuclear fall-out or the expectations of damage from an explosion of the incoming weapon? What would be the environmental effect of a successful intercept of a nuclear weapon over the United States, resulting in a high altitude nuclear explosion? Could electrical and communications systems across the US be destroyed? Could satellites be destroyed? Is it possible that the use of these interceptors to protect U.S. citizens could actually result in unintended destruction? Might other non-U.S. territories, in the path of the weapons, be harmed by interceptions and nuclear explosions above their areas or by debris falling onto their territory? What will be the possible effects on people and the environment on earth below if MDA war fighters actually use their weapons in space or in the skies?

Effect of hazardous and toxic waste on minority communities: As an organization we have a strong concern for human rights and racial justice. We note that the Environmental Impact Assessment requires consideration of undue negative impact on minority communities. It is our understanding that the test sites are mainly on Indian lands or on lands belonging to Marshall Islanders. The statement in the PEIS that *"Environmental justice analyses require information about local communities, and therefore will be analyzed in site specific environmental documentation."* is hardly adequate. We know what damage has been done to such communities already by bombing ranges (as in Puerto Rico) or nuclear weapons testing (as in the South Pacific and on Indian lands in the U.S. southwest). Such an analysis should have been made before the deployment and testing began. The program should be halted until thorough analysis is made, and it should not continue if there is evidence of detrimental effect on these populations and their environment.

We have been able to list only a few of our many concerns about this Draft PEIS, and to discuss them only briefly in our four comment papers.

We are convinced, however, that there are far too many questions for this program to be allowed to proceed. Not only is there a vast array of concerns regarding its adverse effects on the environment, there is also the overriding concern that pursuit of a Ballistic Missile Defense System will destroy all hopes of halting nuclear weapons proliferation and all hopes of continuing to develop as a world community of sovereign nations ruled by law. This system is being designed in a time of peace for global war – and its very existence can make that war inevitable.

We believe that the BMD program should be immediately halted or, at the very least, a moratorium should be declared and a period of full examination of the system, its costs, and its dangers occur. The consequences are too great, the dangers too dire, to let development continue as at present.

In peace,

Ellen Barfield

MDA BMDS PEIS
c/o ICF Consulting
9300 Lee Highway
Fairfax, VA 22031

To whom it may concern,

I am alarmed that the Missile Defense Agency has authorized itself to continue research on Star Wars. I am opposed to any further development of a Star Wars program and strongly believe that such moneys would best be used on programs to improve the nation's health care, the nation's environmental problems, and to broaden educational opportunities for all Americans.

I believe the "no action alternative is an insufficient brake to further Star Wars developments. I strongly urge a intensive rewriting of PEIS

Sincerely, Barbara Cartwright

United States Department of the Interior

OFFICE OF THE SECRETARY
Washington, DC 20240

TAKE PRIDE IN AMERICA

NOV 1 8 2004

ER 04/701

MDA BMDS PEIS
C/O ICF Consulting
9300 Lee Highway
Fairfax, VA 22031

Ladies/Gentlemen:

The United States Department of the Interior has reviewed the Department of the Defense, Missile Defense Agency's (MDA) draft programmatic environmental impact statement (DPEIS) for the Ballistic Missile Defense System (BMDS) and offers the following comments.

Air Quality and Pollution

The Department's National Park Service (NPS) commends the MDA for recognizing that review requirements under the National Environmental Policy Act (NEPA) are not the same as those involving conformity and its willingness to comply with both NEPA and the conformity regulations. The Department also commends the MDA for examining potential impacts on air quality, including its recognition of visibility as an important issue, and looks forward to future reports that include an examination of visibility impacts.

Section 3.1.3 Biological Resources

Pages 3-16 to 3-17: The portion titled "Definition and Description" emphasizes consideration of Federal and State listed species, or species proposed for listing. However, NEPA requires that other species that may be impacted by the proposed activity must also be evaluated throughout the DPEIS. See also page 4-42, subportion "Launch/Flight Activities," where impacts to only species of concern are addressed. We recommend that the DPEIS address all applicable species

Pages 3-17 to 3-18: In the portion titled "Impact Assessment," we recommend the following text be inserted to address requirements in the referenced laws:

> If the proponent of the proposed activity determines that migratory bird species may be adversely impacted, then the proponent should confer with the Department's Fish and Wildlife Service's (FWS) Regional Migratory Bird Program to ensure compliance with the Migratory Bird Treaty Act (MBTA) and the Bald and Golden Eagle Protection Act, where applicable. Under the MBTA, the taking of migratory birds is not authorized without a permit. The project proponent should also confer with the Service to determine if conservation measures may be implemented to minimize or avoid take of migratory birds.

Page 3-19. In the subportion "Determination of Significance," we recommend that reference to the MBTA be incorporated. We also recommend that the final PEIS indicate that military readiness activities implemented in the future by the MDA should be in compliance with the rule currently being finalized by the Service, "Migratory Bird Permits: Take of Migratory Birds by DoD."

Section 3.1.9 Land Use

Page 3-31: In the portion titled "Impact assessment," we suggest referencing the Service National Wildlife Refuges.

Section 4.1.1.1 Weapons – Lasers

Page 4-26: In the portion titled "Biological Resources," under the subportion "Land and Sea Operating Environments," we recommend adding text that indicates that hydrochloric acid could have an effect on shorebirds and waterbirds (in addition to waterfowl, which are already referenced).

Page 4-27: In the last paragraph under the subportion referenced above, we recommend that the text specify the maximum noise level, if available, for which animals "generally return to normal activities within a short time following noise disturbance." Most wildlife has a limited tolerance to noise. We recommend specifying the threshold at which this tolerance level would generally be exceeded and when adverse effects may occur. See also page 4-43 where impacts to birds from noise disturbance are discussed in greater detail. These two sections should be in agreement with each other. The statement on page 4-27 is not in concurrence with the discussions on page 4-43, which indicate there may be more than minor disturbances

Section 4.1.1.3 Sensors – Radars

Page 4-64 to 4-65: We believe the analysis of impacts on birds from radar in the "Biological Resources" portion is outdated and inadequate. The first paragraph of this portion does not address the potential effects of radar on very large flocks of migrating birds. Even if a bird is not "within the most intense area of the beam for any considerable length of time," there is insufficient evidence to support the statement that no significant adverse impacts to birds would occur. The 1993 report that is referenced to support this conclusion is outdated.

We recommend the analysis describe what constitutes a "relatively small" beam size. A beam going through a dense flock could have an adverse effect on birds, particularly for those species which are already significantly in decline. We recommend that this potential adverse effect be described.

We recommend that this section discuss the potential of using NEXRAD (Next Generation Weather Radar) to help evaluate when large flocks may be in the testing area. NEXRAD could provide valuable information regarding times when testing should not occur to reduce biological impacts. This technology is currently being used by the Air Force to reduce the potential for air strikes and by the Department of Defense to identify important stopover habitat in relation to Department of Defense installations.

We recommend that an avian physiologist, particularly one very knowledgeable of electromagnetic radiation, carefully review the effects of this proposed activity.

In reference to the Cobra Dane study, it should be noted in the DPEIS that arctic foxes, which are very efficient predators, are present on Shemya and other Aleutian Islands, and would quickly remove evidence of any bird kills. Lack of evidence of bird die-offs under these conditions does not provide solid evidence that they aren't occurring.

Bird collisions with radar equipment, particularly towers, can have significant impacts on birds. Estimated annual bird kills from collisions with communication towers (radio, television, cellular, and microwave) range from four- to five-million, both from direct collisions with the towers themselves and with guy wires. Tall radar towers, i.e., those above 199 feet MSL (mean sea level), are of particular concern. The greatest impact occurring from towers illuminated at night with solid or pulsating incandescent red lights. In addition, the potential for tower collisions significantly increases at night under cloudy or otherwise low visibility conditions.

Because of these impacts, the MDA should follow the FWS's "Interim Guidelines For Recommendations On Communications Tower Siting, Construction, Operation, and Decommissioning - 2000," for both existing and proposed radar towers. These guidelines should be referenced in the DPEIS as applying to radar equipment. They also should be applied to Re-Radiation Towers discussed in the second paragraph on page 4-77.

Section 4.1.1.5 Sensors - Laser Sensors

Page 4-73: Under the portion titled "Biological Resources," we have similar concerns for potential impacts on migratory birds from laser sensors as those stated above for radar equipment. This is particularly true for the use of land and sea-based lasers and in situations where large flocks may be present. Although the lasers may not directly hit birds or other wildlife on the ground, impacts to birds in the air could be significant. We recommend that these potential impacts be described.

Regarding the Nominal Ocular Hazard Distance, the DPEIS concludes that impacts to wildlife from a space-based laser sensor would be insignificant because it is unlikely that the laser would be directed towards the Earth's surface and, if it were, distortion from atmospheric conditions would reduce the radiance level. It further concludes that the Earth's surface would likely be beyond the Nominal Ocular Hazard Distance. This conclusion is not well supported. We recommend that the DPEIS identify how "likely" it is that the Earth's surface would not be beyond this specified distance.

Section 4.1.1.9 Support Assets - Infrastructure

Page 4-89 to 4-90: In reference to the first paragraph under "Biological Resources," we note that the construction of infrastructure, depending upon its extent, can significantly increase surface runoff. This can negatively impact surrounding habitats, particularly wetlands and other sensitive habitats. Impacts to fish, wildlife, and plants from pollutants could be more than temporary depending upon the pollutant and length of exposure. Depending upon the species in the project area, construction could have a larger area of disturbance than 50-feet, particularly for nesting bird species. We recommend that this section describe these possible impacts.

We recommend that the second paragraph indicate that site preparation and installation could negatively impact waterbirds utilizing the shore environment, particularly during breeding season.

In the third paragraph, we recommend that the description of behavioral responses to construction include nest abandonment and alteration of migration routes of larger mammals.

We recommend that the fifth paragraph list compliance with the Marine Mammal Protection Act, the Migratory Bird Treaty Act, and the Bald and Golden Eagle Protection Act as required, where applicable. These regulatory references should also be inserted in the portion titled "Biological Resources" under Section 4.1.1.10 Support Assets - Test Assets.

Section 4.1.2.3 Biological Resources

Page 4-105: Under "Integrated Ground Tests," we believe that the conclusion of insignificant impacts is not sufficiently justified or supported. This section lacks information regarding the size and orientation of the operating radar sensors. It also does not describe the anticipated increased number of these operating radar sensors.

Section 4.4 Adverse Environmental Effects That Cannot Be Avoided

Page 4-133: As stated above, we believe that statements of no significant impact are not sufficiently justified or supported. This section indicates Best Management Practices would be implemented to mitigate adverse effects. However, the DPEIS does not provide sufficient information regarding what these measures might be or what would be recommended. In addition, the conclusion that "those [effects] that could not be avoided should not result in a significant impact to the environment" could be viewed as arbitrary since those effects are insufficiently described.

Appendix H Biome Descriptions

Page H-106: We suggest expanding the discussion of "environmentally sensitive habitat" for the savanna biome. Currently, the discussion consists only of the following two sentences: "National parks and reserves have been established to preserve and protect threatened vegetative

and wildlife species in the Savanna Biome. There are several National Wildlife Refuges along the Gulf Coast."

Technical Comments and Suggested Corrections:

Appendix G Applicable Legal Requirements

Page G-10:

- Under the heading United States, in the first line and after the phrase "The Endangered Species Act of 1973" add, "as amended."
- After the phrase "requires all Federal," delete "departments and" so the line reads "requires all Federal agencies to seek."
- In the second line, delete the word "species" after "endangered."
- In the third line, after the phrase "The Secretary of the Interior was directed," insert "by the Endangered Species Act."
- In the fourth line, after the phrase "Endangered species" replace "designation" with "listing."
- In the second paragraph, last line, delete "an adequate" and insert "integrated"; delete the phrase "in place at the sites" and replace it with "determined to be of benefit to the species", so the line reads ... "from critical habitat designations if an integrated natural resource management plan is determined to be of benefit to the species."

Appendix H Biome Descriptions

Page H-7:

- The scientific name of the northern sea otter is *Enhydra lutris*, not *Eumetopias jubatus*.

Page H-39:

- In a discussion of the deciduous forest biome in the northeastern States, red spruce and balsam fir forest types are listed. We note that spruce and fir are evergreen conifers, and forests dominated by them are not generally considered components of a deciduous forest biome. We also note that the preceding description of the taiga biome on pages H-16 through H-29 does not refer to balsam fir, its most prevalent tree species.
- Tropical and subtropical moist broadleaf forests are described as components of the biome; as the text notes, these forests are "dominated by semi-evergreen and evergreen tree species" and thus may be out of place in discussion of a deciduous forest biome.

- A list of examples of "threatened and endangered vegetation [sic]" in this biome includes three species from the eastern and southern U.S. and a species of moss endemic to evergreen (not deciduous) forest on the island of Madeira, which may not be the best grouping of examples to illustrate listed species in the "inland deciduous forest biome."

Page H-40:

- The discussion of wildlife of the deciduous forest biome indicates that the Florida panther "...inhabit[s] the lower coastal plains and flatlands of the middle portion of this biome." The Florida panther is found only in peninsular Florida, which would not be considered the middle portion of this biome. We suggest making this clear or deleting reference to the Florida panther is this statement.

Page H-41:

- A list of threatened and endangered wildlife includes the American black bear as if it were listed range wide; however, it is the Louisiana subspecies (*Ursus americanus luteolus*) that is actually listed as Federally threatened. *Ursus americanus* is listed as threatened due to "similarity of appearance (T (S/A))" throughout the historic range of the Louisiana black bear, which includes Louisiana, Texas, and Mississippi and is, therefore, subject to a special rule as outlined in 50 CFR 17.40(i). The black bear is not federally listed throughout the remainder of its range.
- The species *Achatinella mustelina* is attributed to hammocks in the Everglades; however, it is a snail endemic to tropical evergreen forests in Hawaii.
- The West Indian manatee is incorrectly given the scientific name of an African species (*Trichechus senegalensis*). It is correctly identified as *Trichechus manatus* in Exhibit H-6 on page H-42.

Page H-42:

- The scientific name of the leatherback sea turtle is *Dermochelys coriacea*, the DPEIS incorrectly identifies its scientific name as *Ammospiza caudacuta*.

Page H-43:

- Gorillas are incorrectly listed as inhabitants of East Asian tropical and subtropical moist forest.

Page H-90:

- *Ostrya virginiana* is given as the scientific name of the ironwood introduced on Pacific islands. However, this is a species of eastern North America; it is likely the author had in mind a species of *Casuarina*, also commonly known as ironwood.

Page H-93:

- *Esox lucius*, the northern pike, is attributed to offshore areas near the Pacific Missile Range on Kauai; however, this species is not found in the waters around the Hawaiian Islands. It is likely the author had a different species in mind.

Page H-104:

- In a discussion of the savanna biome, the harpy eagle is listed as one of its "common bird species." However, this eagle is an extremely rare bird of deep forest habitats.

We appreciate the opportunity to provide these comments. Should you have any questions please do not hesitate to c

Sincerely,

Willie R. Taylor

Missile Defense Agency
Ballistic Missile Defense System PEIS
c/o ICF Consulting
9300 Lee Highway
Fairfax, VA 22031

Dear Mr. Lehner:

In accordance with our responsibilities under Section 309 of the Clean Air Act and the National Environmental Policy Act (NEPA), the Environmental Protection Agency (EPA) has reviewed the Missile Defense Agency's (MDA) Ballistic Missile Defense System (BMDS) Draft Programmatic Environmental Impact Statement (DPEIS) (CEQ # 040438).

The DPEIS identifies, evaluates and documents, at the programmatic level, the potential environmental impacts of activities associated with the development, testing, deployment, and planning for the eventual decommissioning of the BMDS. It considers the current technology components, support assets, and programs that make up the proposed BMDS as well as the development and application of new technologies.

EPA commends the efforts that MDA has commenced in p comprehensive and well organized document. We also appreciate the extensive environmental analysis that is available for many of the the proposed BMDS. Based on our review of the DPEIS, we have rate - Lack of Objections (see attached "Summary of EPA Rating System"). Although EPA has no objections to the proposed action, there are a few issues that should be clarified.

1) General Comments:

a. To assess the impacts of implementing the proposed BMDS, the DPEIS characterized the existing condition of the affected environment in the locations where various BMDS implementation activities are proposed to occur. MDA has determined that activities associated with the proposed BMDS might occur in locations around the world. Therefore, the affected environment has been considered in terms of global biomes, broad ocean areas, and the atmosphere. This has resulted in the DPEIS being very conceptual and general in nature. EPA understands that once potential BMDS locations are determined, more detailed site-specific documents will be prepared. Through the discussions on the "block approach" or the "block development process", the DPEIS has given clear indications of when follow-on NEPA analysis will occur. We agree with this approach. However, while the documents give representative examples of past, current, or proposed locations where proposed activities may occur within each biome, EPA recommends that the EIS discuss the criteria that MDA will use in making future decisions for site-specific locations.

b. The resource areas considered in this analysis are those resources that MDA believes can potentially be affected by implementing the proposed BMDS. EPA agrees that some resource areas are site-specific or local in nature and, therefore, cannot be effectively analyzed in this type of programmatic document and that the potential impacts on these resources are more appropriately discussed in subsequent site-specific documentation tiered from this PEIS. However, EPA recommends that the final document discuss the existence of multiple species habitat conservation planning efforts that are proximate to DoD lands and the potential impacts of debris on marine and aquatic ecosystems.

c. As suggested by CEQ regulations, MDA has taken advantage of the extensive environmental analyses that already exist for many of the existing components of the proposed BMDS by incorporating these materials into the DPEIS by reference. However, some of these documents are greater than 10 years old. The PEIS should confirm the validity of the information in these documents.

2) Perchlorate Comment: Because there have been differing interpretations of the science associated with the impact on human health from low level exposure to perchlorate and in the interest of resolving scientific questions, EPA, the Department of Defense, the Department of Energy, and the National Aeronautics and Space Administration - members of a broader Interagency Working Group on Perchlorate led by the Office of Science and Technology Policy - have referred scientific issues and EPA's 2002 Draft Health Assessment on Perchlorate to the National Academy of Science (NAS) for review. NAS is currently conducting a study to determine the best science and model to use for determining the health impacts and standards for perchlorate. A report on this study is expected to be completed by the end of 2004. EPA recommends that the results of the report be incorporated into the FPEIS.

We appreciate the opportunity to review this DPEIS. We also look forward to reviewing the FPEIS related to this project. The staff contact for the review is
can

Sincerely,

Anne Norton Miller
Director
Office of Federal Activities

Enclosure: Summary of Rating Definitions

SUMMARY OF EPA RATING SYSTEM

Rating the Environmental Impact of the Action

- **LO (Lack of Objections)** The review has not identified any potential environmental impacts requiring substantive changes to the preferred alternative. The review may have disclosed opportunities for application of mitigation measures that could be accomplished with no more than minor changes to the proposed action.
- **EC (Environmental Concerns)** The review has identified environmental impacts that should be avoided in order to fully protect the environment. Corrective measures may require changes to the preferred alternative or application of mitigation measures that can reduce the environmental impact.
- **EO (Environmental Objections)** The review has identified significant environmental impacts that should be avoided in order to adequately protect the environment. Corrective measures may require substantial changes to the preferred alternative or consideration of some other project alternative (including the no action alternative or a new alternative). The basis for environmental objections can include situations:
    1. *Where an action might violate or be inconsistent with achievement or maintenance of a national environmental standard;*
    2. *Where the Federal agency violates its own substantive environmental requirements that relate to EPA's areas of jurisdiction or expertise;*
    3. *Where there is a violation of an EPA policy declaration;*
    4. *Where there are no applicable standards or where applicable standards will not be violated but there is potential for significant environmental degradation that could be corrected by project modification or other feasible alternatives; or*
    5. *Where proceeding with the proposed action would set a precedent for future actions that collectively could result in significant environmental impacts.*
- **EU (Environmentally Unsatisfactory)** The review has identified adverse environmental impacts that are of sufficient magnitude that EPA believes the proposed action must not proceed as proposed. The basis for an environmentally unsatisfactory determination consists of identification of environmentally objectionable impacts as defined above and one or more of the following conditions:
    1. *The potential violation of or inconsistency with a national environmental standard is substantive and/or will occur on a long-term basis;*
    2. *There are no applicable standards but the severity, duration, or geographical scope of the impacts associated with the proposed action warrant special attention; or*
    3. *The potential environmental impacts resulting from the proposed action are of national importance because of the threat to national environmental resources or to environmental policies.*

Adequacy of the Impact Statement

- **Category 1 (Adequate)** The draft EIS adequately sets forth the environmental impact(s) of the preferred alternative and those of the alternatives reasonably available to the project or action. No further analysis or data collection is necessary, but the reviewer may suggest the addition of clarifying language or information.
- **Category 2 (Insufficient Information)** The draft EIS does not contain sufficient information to fully assess environmental impacts that should be avoided in order to fully protect the environment, or the reviewer has identified new reasonably available alternatives that are within the spectrum of alternatives analyzed in the draft EIS, which could reduce the environmental impacts of the proposal. The identified additional information, data, analyses, or discussion should be included in the final EIS.
- **Category 3 (Inadequate)** The draft EIS does not adequately assess the potentially significant environmental impacts of the proposal, or the reviewer has identified new, reasonably available, alternatives, that are outside of the spectrum of alternatives analyzed in the draft EIS, which should be analyzed in order to reduce the potentially significant environmental impacts. The identified additional information, data, analyses, or discussions are of such a magnitude that they should have full public review at a draft stage. This rating indicates EPA's belief that the draft EIS does not meet the purposes of NEPA and/or the Section 309 review, and thus should be formally revised and made available for public comment in a supplemental or revised draft EIS.

Rick Lehner
c/o ICF Consulting
9300 Lee Highway
Fairfax, VA 22031

Dear Mr. Rick Lehner,

I am writing today to support the "No Action" alternative to deploying a missile defense system. The United States should not deploy a missile defense system unless it will improve the overall ecological, political, and security environment. On all three grounds, the proposed system fails.

Deployment of the Bush administration's proposed missile defense system threatens the global environment. It will increase the likelihood of a nuclear catastrophe by impelling Russia to maintain a larger nuclear arsenal on high alert than it otherwise would, and by driving China to build and deploy a larger arsenal than it otherwise would. The impact of a nuclear war, either accidental or intentional, would dwarf any other environmental nightmare scenario one can envision.

Moreover, the system does nothing to improve our security environment. It has yet to be tested in realistic conditions and would be ineffective against a real attack.

Deployment should be halted until the Programmatic Environmental Impact Statement is finished and the system succeeds in realistic testing.

It is also my understanding that the deployment is being made without the radar system because it is faulty. How, might I ask will a missile be guided?

Sincerely,

James Roberts

[illegible]

October 14, 2004

Rick Lehner
c/o ICF Consulting
9300 Lee Highway
Fairfax, VA 22031

Dear Mr. Rick Lehner,

I am writing today to support the "No Action" alternative to deploying a missile defense system. My perspective is that of a long time resident of Interior Alaska familiar with the Fort Greely area where one of the missle sites is currently under development. Unfortunately, the selection of this site was not adequately evaluated in relation to the environmental sensitivity of this area. Inadequate consideration was given to the fact that the site sits on top of the flowage of a unique aquifer that flows through the glacial outwash gravels from the Alaska Range mountains to the south, under Fort Greely, and emerges as springs that feed the Delta Clearwater River and lake system. Because of the upwelling water of the Delta Clearwater system it is one of the most productive salmon spawning complex and young salmon rearing area on the entire Yukon-Tanana River system. Any significant leakage or spill of contaminants, inclusive of fuels, and radioactively contaminated water or other materials would have the potential for devastation to both the commercial and subsistence fisheries of the Yukon River aned Bering Sea through direct affects on the fish, as well as the thousands of people dependent upon the fish for their nutrition, health, and economy. Additional studies need to be done to assess this potential threat to the Alaskan environment and its people and to assess the possible need for mitigative planning, spill contigency development, and testing for background leakage levels from the post World War II use of Fort Greely as a biological and chemical warfare testing site. The United States should not deploy a missile defense system unless it will improve the overall ecological, political, and security environment. On all three grounds, the proposed system fails.

Deployment of the Bush administration's proposed missile defense system threatens the global environment. It will increase the likelihood of a nuclear catastrophe by impelling Russia to maintain a larger nuclear arsenal on high alert than it otherwise would, and by driving China to build and deploy a larger arsenal than it otherwise would. The impact of a nuclear war, either accidental or intentional, would dwarf any other environmental nightmare scenario one can envision.

Moreover, the system does nothing to improve our security environment. It has yet to be tested in realistic conditions and would be ineffective against a real attack.

Any decision for deployment should be delayed, at least until the Programmatic Environmental Impact Statement is finished and the system testing is completed.

Sincerely,

DC_O0002

BMDS PEIS
Comment Form

Name: Angy Chambers (POC)
Organization: 45 CES/CEV

Address1:
Address2:

Comments:

From 45 SW/JA (Capt. Elizabeth Patrolia),

Pages 4-84 and 4-90 -The sentence reads, " Should the impacts affect a threatened or an endangered species or its habitat, essential fish habitat, jurisdictional wetlands, or another regulated resource then in addition to analysis under NEPA and other applicable laws (Clean Water Act, Endangered Species Act), regulatory agency consultation would be required."

Although this is a true statement, we believe it can be phrased more concisely. The language as written suggests that section 7 consultation under the Endangered Species act will be obtained when and if during the course of our actions we impact a threatened or endangered species. 50 C.F.R. 402.10 (a) states, "...The conference is designed to assist the Federal agency and any applicant in identifying and resolving potential conflicts at an early stage in the planning process."

This statement in the code leads us to the conclusion that we should attempt to consult prior to adverse affects on endangered species when known in advance. We suggest adding this additional sentence to follow what was quoted in the first paragraph, "The appropriate federal agency must be consulted under section 7 of the Endangered Species Act when site specific analysis indicates the continued existence of a threatened or endangered species is likely to be jeopardized."

From Brian Barfus (Environmental Support Contract),

CCAFS has tremendous infrastructure to support this project and many organizations to provide various environmental services such as hazardous waste disposal for such a project. It is not possible to predict the impacts on this facility until we get a better idea as to what activities will take place at CCAFS. Will there be any new facilities constructed? Can present organizations provide the required services to support the new activities and associated support facilities for this project? We need this kind of information to properly evaluate the environmental impacts of this project at CCAFS.

From Angy Chambers (45 CES/CEV),

No comments at this time. Further documentation would be required in order to assess impacts to natural/cultural resources at Cape Canaveral AFS.

DC_PHO0007

Good evening everyone. Thank you for the opportunity to have citizens' comments. I think we've said that the environment is much broader than what this statement calls for. The environment is a social and cultural environment that we need to take into consideration as we consider building such a new and costly provocative system.

The National Intelligence Estimate of 2001 for the Bush Administration says, and I quote, An attack on U.S. territories is more likely to be -- we are more likely to be attacked by countries or terrorists by using ships, trucks, airplanes or other means, rather than long-range ballistic missiles.

We're still in the era of the Cold War in thinking about these missiles and this program to create this artificial and flawed umbrella for the people of this country. What are the effects on other countries of this provacative system? It is thought likely that China will increase its production of nuclear weapons to overwhelm this system, which is very easily overwhelmed by decoys and numbers. This system, as we now know it, is meant to ideally knock out a very few incoming missiles, not at all the kind of attack that possibly could occur. It is flawed in that respect.

The Pentagon itself in an analysis called the Ballistic Missile Defense System, a Case Study Against Rushing Forward on a Missile System. The Pentagon itself said that. And yet we're -- we have spent a hundred billion dollars. We're planning to spend 83 billion more over the next ten years and we have nothing to show for it except neglected communities, depleted healthcare systems and actual environmental neglect of the real environments that we all daily live in.

This proposal that we're asked to address tonight does not contain a real No Option Alternative not to build the system, to abandon it. That is what I think most of the people in the United States and the world would affirm. This system's impact on traditional arms control and disarmament efforts would be profound. We've already vitiated the Anti-Ballistic Missile Treaty under this Administration. We're preparing to resume nuclear weapons testing at the Nevada test site. We're building a whole series of new nuclear weapons, the mini nukes and bunker buzzards.

We're prepared to fight preemptive wars and yet this antiquated system that is going to cost you and I and our fellow Americans the treasures of our society that are already depleted by the Iraq war and other weapons spending, we're asked to do this. And I say we must abandon this program and utilize our resources in more constructive ways and practicing the ways of diplomacy negotiations and building alliances, instead of acting unilaterally, which is what this program does. Thank you.

DC_PHO0009

Hi. I came here from Salinas to speak on this. And in Salinas they're proposing closing all of our public libraries. Why? Because they don't have enough money. Well, where is the money going? I propose that 1.3 trillion dollars for Star Wars is a good example of where the money is going. Closing all of the public libraries completely in a town that is 66 percent Hispanic American, in a town that produces 80 percent of the lettuce you eat.

Let's take a look at what the program is. And I'll address it environmentally. I have copies of my statements if anybody wants it. Here you go. Here. Pass them around. Statements from MacGregor Eddy. I'm an advisory board member of the Global Network Against Weapons and Nuclear Power in Space regarding the Programmatic Impact Statement of the PEIS Ballistic Missile System presented October 19th, Sacramento, California. One, the 515 launches which is far more than the 99 commercial launches that are proposed.

By the way, I came here expecting a fairly honest presentation of the PEIS and I was shocked at the scummy lies I heard by people I regard as honest people. It's ridiculous that the -- there is 515 launches proposed for Star Wars. That is five times the amount that would be launched under the programs that are non-Star Wars. And you can look this up for yourself. Don't trust me. Check it out.

The second thing is the PEIS is based on the Star Wars program as proposed -- and here we have a statement. Okay. This statement was made by General Henry Tray Obering. He's the head of the Missile Defense Agency. So this is not a statement from some conspiracy website. This is a statement from the head of the MDA. What did he say when he was speaking at a Homeland Security conference on a missile defense panel on October 13th in Colorado Springs, Colorado? He was asked about the THAAD, which is the Theater High Altitude Defense Missiles that are scheduled to go into production in 2005. He was asked about these. What did General -- General Henry Tray Obering say about the missiles? He said, quote, These missiles are intended to augment, not replace, the current generation of ground-based midcourse interceptors.

That is what we're talking about here tonight, ground-based midcourse interceptors. In fact, there will be a continued spiraling of the capabilities of missile network with more missiles and additional sites added to the current missiles and expansion of the Theater High Altitude Defense Missiles beyond the initial scheduled 25 missiles. Therefore -- hey, listen. Therefore, the program they're talking about includes far more missiles than the ones they're proposing.

The second thing is the PEIS does not evaluate the environmental impact of No Action Alternative; thus, does not comply to the National Environmental Policy Act. And three, the PEIS does not address the environmental impact of the response to ballistic missile defense systems by other countries. For example, China is planning to increase the number of missiles they have in direct response to our ballistic missile program. And this PE -- this Environmental Impact Report does not address the effect of testing,

deployment and decommissioning of these two missiles in China, which is a direct result of our policy. And this is not included in the Environmental Impact Report.

The report -- since No Action Alternative was not considered seriously in the impact report, I say it is not an impact report at all. Therefore, it has not complied with the legal requirements; therefore, it should be stopped. Thank you.

DC_PHO0010

I'm Rod Macdonald. I'm a professional wetland scientist. I work with identifying wetland ecosystems, their components, soils, water quality, their functionality. I modify them, restore them, recreate them under occasion, so forth. So I know what I'm talking about. I'm a registered wetland scientist, which means, like a structural engineer, I'm educated. But I have a reputation to lose, if I don't get the facts right.

I guess what disturbs me is I read Science Magazine. It comes out 52 times a year. It's uncensored. You'd be surprised of the things you'll see in there. Anyway, there is a lot of discussion about missile systems that comes from the point of view of the National Academy of Science. And, of course, there is a broad range of opinions of scientists, like anyone else. It's sort of a scientific engineer-based discussion.

I want to talk about what an Environmental Impact Statement is supposed to be under the NEPA, National Environmental Quality Act. It's supposed to look at a cradle-to-grave analysis of a project. It's supposed to minimize the impact at every state, in every level, every decision within it. I really think it's a great thing to take a program like this which has a huge cumulative impact and look at it in a systematic cumulative way. That's what it says it does; but, unfortunately, it's not what it does. It provides a false set of figures upon which to compare what the real impacts would be. Instead of trying to look at where we have to go if we want to deploy the system -- I'm not willing to take a stand about whether I agree the system should or shouldn't be built. I think despite all terrorism, the possibility of a missile launched from a disguised container off of the coast is realistic and we'll never know who put it in that container but we'll need to shoot it down.

But my argument isn't with the waste of money, if it may be an overblown system or its provocative nature; but, instead, it really does not address what is going on. And the reason it doesn't is it provides -- I'll look at perchlorates. Perchlorates are important to amphibians. Amphibians are in a worldwide decrease. If you look at the report, all the report ever says is "hazardous waste will be handled and dispersed in accordance with appropriate regulations; therefore, no significant hazardous materials and hazardous waste impact will be expected."

They go through and they say this for every single thing. The vegetation and so forth won't be or "we'll do a tiered-site analysis and a certain site will be affected" but it won't. But the truth is over the decade life of the program, the global level of perchlorates may rise. Amphibians skin needs to be moist. They're very sensitive to all industrial chemicals. Seventy percent of the species are in decline right now, even in habitats that aren't disturbed. Why would we care about them? The mosquitos are coming out. We don't have hard figures. We don't have real analysis. We're told this is a half a percent. What they're disguising there is most of the chemicals are residual from former manufacturing processes. And even so, the largest contributor -- as a scientist, I'm simply telling you, the largest contributor actually is the manufacturing, testing, open detonation of old rocket motors and the whole thing.

DC_PHO0010

Just to say there would be no impact -- this is a negative deck. We've all seen negative decks. They go through and check off negative deck. Negative deck. Negative deck. This isn't an honest -- this isn't a scientific discussion. I'm aware of what NEIR is. I've dealt with them for 25 years. Thanks.

DC_PHO0011

The PEIS underplays many environmental effects of the BMDS. The Ballistic Missile -- I'm sorry. The Ballistic Missile Defense System PEIS does not address several of my scoping comments to start with and does not adequately address several risks, including exposure to increased levels of toxic pollutants from a dramatic increase of missile launches.

As we know, the -- the perchlorates are used in the self-propellants in the formation of a key thyroid hormone which are critical for growth and development of fetuses and children. The PEIS proposes to allow over thirty-fold higher levels of perchlorate at 200 parts per billion than proposed by the State of California, which is six parts per billion. Thus, many rocket launches will inject chemicals including aluminum oxide, hydrogen chloride and hydrochloric acid directly into the upper atmosphere, thereby depleting the ozone. The PEIS does not address the direct injection of the chemicals high into the atmosphere.

Secondly, the BMDS PEIS underestimates the risk of health and safety of BMDS missiles accidentally shooting down civilian and/or friendly military aircraft. BMDS has failed to mention the U.S. missile systems have a history of accidentally shooting down aircraft. Consider the U.S. has seen the Pac-3 missiles, which are -- which are in the PEIS, actually shot down several U.S and allied jets -- two or three in this case of -- I'm sorry -- in two of the cases of the recent invasion of Iraq. There is also Flight TWA 800. And even though several people saw streaks going up toward it, the people that saw it were never allowed to testify. The -- the point is that the activation of the BMDS risk accidentally shooting down civilian airliners is not even considered in the BMDS. It's a risk to health and safety.

While the BMDS states that warning will be provided to enable time to clear the air space, it's highly doubtful that such time would be allowed in such an emergency. Also, the PEIS underestimates the effects of space to reach from high altitude midcourse missile intercepts in the destruction of satellites, particularly at high altitude.

Furthermore, while the PEIS considers testing the BMDS on targets of opportunity, no mention is of the space debris resulting from U.S. targets of opportunity or other nations' targets of opportunity. The environmental consequences of mini rocket launches needed to deploy and maintain space-based interceptors has not been adequately considered, nor has its environmental consequences of the fuel. They talk about having all of the -- these -- in other words, in Option 2, they have many different interceptors in space that would have a reduced environmental consequence. But there's no consideration you have to launch all of those missiles in the place to get there.

Also, will the space-based satellites use nuclear power sources? Will any BMDS interceptors use nuclear warheads? This was not clearly defined. This is unsatisfactory. The BMDS does not include a real No Action Alternative. Such an alternative does not include further development and testing and deployment of these weapon systems needs

DC_PHO0011

to be considered and included in the PEIS. The PEIS does not consider a No Action Alternative at all. In other words, something that would involve rejoining the UN and -- and many other nations of the world in order to enhance security through treaties and arms control, sovereign approaches; i.e., approaches that provided us with long-term security to date.

Also, the PEIS, has not considered any -- has not considered any radioactive follow-up from interceptive missiles. The effects of war are not excluded for the analysis of NEPA. However, the proposed BMDS action is likely to promote a worldwide weapons of mass destruction arms race and force other nations to prepare a massive retaliation against the U.S., should war ensue. Since the proposed BMDS is very likely to cause a massive arms race, the environmental consequences of a resulting war with nuclear and other weapons of mass destruction should not be ignored.

The PEIS needs to consider the environmental effects that follow up from interceptive weapons of mass destruction, as well as effects of weapons of mass destruction the BMDS fails to intercept. This needs to be considered relative to a true No Action Alternative. Thank you.

DC_PHO0013

Hi. I'm Dan Bacher, Central American Action Committee member and long-time environmental and peace activist. And I suggest an Alternative Number 4, which means scrap the entire PEIS and the whole program that they are presenting here. This is a colossal waste of taxpayers money that could be spent on just about anything else other than this and it would be productive. There is a hundred billion dollars that have been spent and another 83 billion that are planned to be spent over the ten years if this Star Wars goes into effect.

The crazy thing about this is there is no imminent threat of weapons of mass destruction or space weapons at least on Earth. I have three questions that I'd like included in the comment period of the document.

Number 1, are we afraid of the zany folks from Zetaraticuli from launching ballistic missiles at Washington, D.C.? Are we terrified of the peaceful and highly evolved inhabitants of Europa from launching WMD's at New York? Number 3, are we afraid of the wonderful civilization of the third planet from Orion launching a massive terrorist attack here on us in Sacramento? No. I don't think so. Unless the government isn't telling us something about this.

Who are we protecting ourselves against? Okay. What I think that -- a better thing than calling this all of the acronyms that have been given out here on this wonderful PowerPoint presentation, I think it could be summed up as "Lost in Space." The people that came up with the Star Wars technologies whole concept are out of their minds. This is the ultimate corporate welfare project.

You know, I -- I'd like to conclude with the fact that we -- we need to get rid of this whole Star Wars project and the PEIS and everything else and get the weapons contractors off welfare. And when I've been out demonstrating I get this stuff from people, "Why don't you get a job?" Well, I've had a job for years. You know, I've been employed the whole time. What I'd like to say to the people that are proposing Star Wars and the Missile Defense System is to get a job, weapons contractors.

DC_PHO0014

Dan is a hard act to follow. Anyway, turning some of the comments that have already been made relating back to the Environmental Impact Report, the Environmental Impact Report has to consider the chain reactions. The report on cutting down old growth Redwoods considers the effect it will have on the spotted owl. The Ballistic Missile Defense program will have effect on a lot more than just spotted owls. It's not only a likelihood, it's a certainty that other countries will react to us developing a Ballistic Missile Defense System, however flawed it might be. And they will react likely by developing more ballistic missiles to overcome the defense system. I've seen nothing in the environmental report on this system that takes into account how other countries will react.

So the effects of the more missile launches, more rocket fuel contaminates going into the water, more depletion of the ozone are not just those of the Ballistic Missile System being described here. All of the effects of the proliferation of ballistic missiles around the world must also be considered in a serious Environmental Impact Report.

Similarly, with the weaponization of space it has been mentioned that other countries are unlikely to be able to afford similar space-based interceptors. Well, the fact is, the U.S. cannot afford this system either. Nevertheless, it wouldn't take much money to send satellites into space to purposely explode and create space debris that would make the space-based interceptors ineffectual and would also make the communication satellites ineffectual and so on and so forth, basically, sabotage space for military and civilian use.

This should be considered quite seriously in an Environmental Impact Report on this system. I don't see any consideration of that. That would be a very simple way another country could stop the whole system. You know the alternative. This has been alluded to. The alternative has to be considered. The alternative of land, sea, air and space-based defense systems are being considered. The alternative of a diplomacy-based defense system is not considered. In fact, diplomacy seems to be a -- a foreign concept to the current Administration.

But as we now know, UN weapons inspections work quite well to eliminate weapons of mass destruction. And similar systems could be deployed around the world, as was deployed in Iraq, and eliminated all of the weapons of mass destruction. These might not meet the needs of Congress, the President and the likes of Dick Cheney and those with egregious economic conflicts of interest, as Dan alluded; but they would meet the needs of the American people.

Talk about showstoppers. This Ballistic Missile System is a threat to the survival of all living species on Earth. That is a very definite showstopper. Thank you.

DC_PHO0018

I'm Darien Delu. I'm connected with the Women's International League for Peace and Freedom, the United States section. It's an honor to get to speak to this body because of the other speakers who have come before me, who have covered so many of the critical points that have to be addressed in the Environmental Impact Statement. We have been presented with a document with 700 pages of inadequate information and sidestepping and general ignoring of the real issues involved. Many of these have been raised already tonight and I'll try not to be too redundant.

The -- NEPA provides for consideration of environmental impacts of the MDA proposals. The MDA PEIS finds only limited environmental consequences for the two proposed alternatives. The so-called No Action Alternative creates a straw dog against which to judge the first two alternatives of the MDA.

The focus of my comments will be two-fold. First, I call for a true No Action Alternative, as have others. For example, or specifically, an alternative that goes beyond the failure to integrate anti-ballistic missile system to an alternative that rejects the individual missile defense elements of a BMD System. Secondly, I point out the unaddressed global environmental impact of an accelerated arms race. Such acceleration, as has been repeatedly pointed out this evening, is entirely predictable as a consequence of the U.S. BMD program.

Because of the devastating impacts -- political, environmental, ecological and psychological, as well as merely environmental -- the impacts of a Ballistic Missile Defense Program of any kind, this PEIS must address a true No Action Alternative. The failure of this PEIS to include such a true No Action Alternative violates the requirements of the NEPA process. The absence of a true No Action Alternative allows the PEIS to construct a false comparison with the other alternatives underplaying the different degrees of environmental damage.

According to the PEIS, the proposed action is needed to protect the U.S. from ballistic missile threats. However, the proposal as -- as a BMDS, a Ballistic Missile Defense System in English, will result in an acceleration of the global arms race. As others have already pointed out, in the case of China, if the U.S. implements a BMDS, other countries will feel called upon to create or increase their missile-based weapons deployment systems as well as their nuclear armament in order to prevent -- in order to present themselves as credible negotiation parties with the U.S. and protect the survivability of their weapons.

As others have already pointed out, the PEIS fails to address the chilling possibilities and associated impacts of an accelerated arms race and its increased missile testing. We're not even talking about the devastation a war would cause. And what about nuclear proliferation? The PEIS does not address the many environmental impacts of the entire nuclear cycle connected to nuclear proliferation. The PEIS points out NEPA excludes

DC_PHO0018

from consideration the environmental impact of a nuclear war or any acts of war. But as human beings, we cannot exclude that in our considerations.

DC_PHO0019

Good evening. I'm Ellen Schwartz. I'm the Co-chair of the Sacramento branch of the Women's International League for Peace and Freedom. And I thank you for the opportunity to speak here. We know from Gulf War I and the War on Terror and the test results to date for the components of the BMDS that the surgical precision with which U.S. weapons are guided makes them excellent instruments for destroying embassies, wedding parties and a hotels full of journalists. In other words, you honored military gentlemen have trouble hitting your backsides with both hands. If you're -- there, is no way that a kinetic weapon -- is that what you call it? -- hitting a missile with an arrow is going to be able to actually hit any significant number of incoming alleged threatening missiles. You're going to have to use nukes in order to get a broad enough range of destruction to take out any of these alleged incoming threats from Alpha Centauri.

Are you going to test them? Are you going to talk about them in the PEIS? Are you going to talk about the environmental impact of testing nuclear weapons in the atmosphere? Or are you just going to lie in the PEIS and, you know, get it installed and say later, "Oops, we have to have nuclear warheads"? The display outside the hall finds uniformly no significant impacts from any of the phases of the BMDS. Emissions will be disbursed by the wind. It's unlikely any animals will get in the way. Of course, no satellite has ever fallen out of orbit and no rocket vehicle has ever blown up on launch so there is no danger of anything ever going wrong.

Even on your own terms without considering the environmental impact of forcing China, Korea, Iran and everybody else in the world to build their own systems to protect themselves from ours, even without considering the possibility that any of these countries including us might use these systems, the BMDS is a disaster waiting to happen. Every weapon built, sited, tested or even decommissioned is a potential disaster.

Your three alternatives assume a program that is going to be implemented whether we do whatever we say here. And the PEIS and this hearing is nothing than a legal formality. You have no true No Action Alternative; only build it together or build it a little bit at a time and don't test it together.

I'm a little offended that all you want to hear about is the environmental impact of this system; whereas the presentation talks about how we'll all be not safe if we don't build it. If the safety of our country from our alleged enemies is on the table, then so is the impact of causing a war.

What you should do in your own terms is to consider a true No Action Alternative, which is an analysis of the relative emissions of greenhouse gasses and space debris and toxic chemicals and radiation caused by either (A), blowing things up or (B), pursuing broader implementations of existing treaties, such as the Nuclear Non-proliferation Treaty and the Anti-Ballistic Missile Treaty, which would not produce any greenhouse gasses, any space debris and would not blind any animal or destroy any life on Earth. Thank you.

DC_PHO0023

First, I'd like to thank you, Colonel Graham and Mr. Bonner and Ms. Shaver and Mr. Duke for coming out here and -- and presenting your material and then hearing what the public has to share. My comments are, I hope, going to be very specific and germane to the PEIS. One of the things I want to point out is that the -- our organization I represent is the Physicians for Social Responsibility in Los Angeles. We have about 5,000 members in Southern california. And we have actually worked with Lenny Segal and I believe you've heard his oral testimony as well as written documents regarding the perchlorate and the lack of information that is present in the PEIS.

Most notably, I would like to point out that the timeline of potentially releasing the final document but two weeks after the oral testimony, as well as what anyone else could offer in writing and -- or even six weeks later into -- in the end of January of '05 strikes me that you very well may not take too seriously what we have to say. I would strongly suggest that you factor a time when you can actually take into account the things that the public are suggesting.

I would like to offer some language for other alternatives which would entail a great deal of work on your part in the MDA office but I think it is absolutely necessary. You're clearly aware of the political decisions that led to the formation of missile defenses, in general, coming out of a decision politically that deterrents were no longer sufficient. I feel that this Administration in making that determination is mistaken. But in addition to that, we haven't tethered out the differences in this document between strategic defense defenses against long-range missiles and those of an -- in a theater defenses. And all previous administrations had kept these two missile defenses segregated. And this Administration has blended the two.

And I think to the detriment because theater defenses have actually a promising future, unlike strategic defenses. Theater defenses can protect troops in the field. Theater defenses can protect cities from attack, overseas especially. And they have actually enjoyed some limited success both in the field of testing as well as in the battlefield and also enjoys bipartisan support. There is actually a realistic threat. There are short-range and medium-range missiles that could actually be fired in hostility at American targets or those allies; unlike the strategic long-range missiles which do not really have a basis in reality.

And in addition, theater defenses have a realistic success because the boost phase of a missile is relatively slow and even the descent of a short-range, medium-range missile is much slower than that of the strategic missile, which could be traveling at 10 kilometers per second, which makes it very unlikely to hit. The alternative, it may be politically impossible for you to do this, but I think you should try to have another alternative which would simply be to keep the -- this is probably the presidential candidate John Kerry's position on these matters -- would be to move ahead on theater defenses but to maintain the strategic weapons that the missile defense is -- against long-range missiles to be held

DC_PHO0023

in research and development stage. And -- and that would be my suggestion for a true alternative.

The other thing I want to bring up is in regards to in the PEIS there is some statements in the effect that some of the space-based interceptors would be placed in geosynchronous orbit, which I believe is some 24,000 kilometers from Earth. To actually get a weapon from 24,000 kilometers out to what would be a low-Earth orbit or even a lower trajectory of a missile within 20 minutes or half hour and do so accurately and to hit the missile is fantasy. And therefore I think the PEIS mischaracterizes any weapon that would be placed in geosynchronous orbit as being an anti-missile weapon. It should simply not be listed as a possibility. That would be -- well, you would be deploying an ASAT -- an anti-satellite weapon. And you should go through the process of actually fielding that before the public and have -- and take your hits for that if, indeed, you're doing that.

The same with the Airborne Laser. There is a very good probability that an Airborne Laser would never work in shooting down a missile in the boost phase and all tests indicate that. But it could be highly effective in a directed energy targeting on Earth for terrestrial targets. And you should be honest about what that weapon might also be used for. It would be helpful to actually not mask the true purposes of some of these weapons.

I believe there needs to be more hearings. The PEIS is insufficient in dealing with cumulative effects, especially in Southern California, as so many of our local contractors are working on the weapons systems. We're bearing the brunt of our environmental impacts of the laser weapon development and many of the rocket launches and the rockets that are being assembled for those launches to launch these 515 launches that may take place over the next 10 years.

I also suggest that you get testimony from the National Recognizance Office, if you have not done so. I'm sure there are considerable concerns about military recognizance assets being false -- being harmed by space debris. Last but not least, I would also suggest that you conduct a space debris analysis, as you have sited in the PEIS, that there may be intercepts as high a 400 kilometers. That either you do testing at 400 kilometers, which is ill-advised because of the debris problem, but how would you know if the weapons work unless you conduct the tests? Or you should actually assume that the weapons won't work because you cannot conduct the tests at 400 kilometers above. Thank you very much.

DC_PHO0024

So this is a show, as we have showstoppers. I'm confused. Well, actually, I -- I was confused by the glossary. It's five pages long and single spaced. And I haven't started yet. The New York Times magazine two days ago asked Wlodzimierz Cimoszewicz, Poland's Foreign Minister to the United States about Polish defense minister, Jerzy Szmajdzinski who recently announced plans to pull all 2500 Polish troops from Iraq next year. Cimoszewicz answered, "It's not true. Our minister of defense mentioned that we would like to end our mission at the end of 2005 but that is not the official position of the government." But when the Times asked Cimoszewics if he had met with the families of the 13 Polish soldiers who died in Iraq, Foreign Minister had replied, "No. I have not."

The Polish government was officially represented by the minister of defense. Which begs the question: Has the defense minister been demoted to coroner/chaplain or how many dead Poles does it take to end the U.S. war in Iraq? Furthermore, Polish Foreign Minister Cimoszewics confirmed the Times figure that 70 percent of Polish people oppose the U.S. war in Iraq. What are we afraid of? The Polish public opinion? The so-called insurgent Iraquis taking up arms against U.S. corporate mercenaries like Cal F. Brown and Root and Halaberten? Ari Fleischer's so-called Operation Iraqi Liberation? That was the original term for this attack, O-I-L. Serves to liberate the resources under those inconvenient civilians impeding corporate access.

The Cold War is over but this fact does not deter the Bush crime syndicate from heating things up. There is no peace dividend as it and any surplus saved in the 90's has been spent since the start of the millennium. The world is a decidedly more dangerous place because the Pentagon has run amuck spending half of our income taxes while mortgaging debt so far as our great grandchildren so it can build so-called "kill vehicles."

Meanwhile, the Pentagon mocks our democracy. It plans, tests, builds and imposes terrible weapons of mass destruction. The Pentagon goes through the motions pretending concern about the environment, holding meetings in far away places like Alaska, Hawaii, where 61 people appear; 15 speak forth; and 7 provide written comments representing 280 million U.S. citizens.

Even the congressional "Millionaire Boys Club" does not feign that kind of representative democracy. The Pentagon does not even care about the speaking and writing concerned citizens. Its Notice of Intent in the Federal Register states the weapons system in question will be used, quote, To defend the forces and territories of the U.S. allies and friends against all classes of ballistic missiles threats in all phases of flights. Which, I suppose, makes the people of the U.S. potential collateral damage.

I imagine the purveyors of the Pentagon portfolio are like the characters in the Beattle's satirical song entitled, "Piggies": Lying, conniving, consuming everything in sight. They never see their evil behavior inflict pain and suffering upon other beings and upon the world. And to get their attention and change their behavior, what they need is a damn

good whacking. Of course, the song is referring to spanking but the Pentagon and spenders can measure its whacking in body counts.

Here in California we analyze public projects and hold them to the test of the California Environmental Quality Act of 1970. When the Pentagon wanted to build a biological nuclear and chemical testing, manufacturing and storage facility at McClellan, UC Davis and Rancho Saco, the community successfully challenged and stopped the bid even before it could be tested by CEQA. The community saw the proverbial writing on the wall. The plan was analyzed. We found it wanting.

The body counts. Yes. Thank you. And I talked about the California Environmental Quality Act, of which I think is great -- well, I think it's good to have an Environmental Quality Act. It's weak but nonetheless it's there. Let me pick up where I was at. Here. Anyway, the community saw the writing on the wall. The plan was analyzed and it was dropped but this -- the same is true of defending BM's. This PEIS reads like a negative declaration.

In case you have not heard, the Cold War is over. This is reason enough for the No Project Alternative CEQA style. It's time for demilitarizing the Pentagon. I'm partial to Helen Caldecott's suggestion that it be converted back to its original design as a hospital. I recommend we just skip the testing, manufacture and storage steps for these weapons systems that are referred to in this EIS and cut to the quick and decommission them all. Take out their fuses and timers and igniters and hire clever chemists to convert their horrible toxins to safe use.

Further, since adults seem to muck things up in the State Department, we should pay and support a coterie of children as ambassadors of peace and reconciliation to all countries on Earth. No more foreign aide. No more foreign debt. The kids will figure it out from there. The spanking should continue upon Pentagon contractors until they change their behaviors. Meanwhile, rescind all Pentagon weapons contracts. No more bucks for bombs. The reason why the Pentagon thinks it needs these weapons systems is because the United States of America has neither learned how not to over consume the planet's resources or stop exploiting human labor. We must become men and women of conscience who believe in and practice trust and respect for one another.

The No Project Alternative, as in CEQA spares us and our planet's ecology while allowing our energies to be spent on truly productive human endeavors. No showstoppers, eh? So this is a show. This PEIS is a non-responsive negative declaration. Thank you very much for your time.

DC_PHO0025

I'm Dr. Leonard Fisher, retired faculty member of medicine at UCLA and volunteer physician at the LA Free Clinic and a member of Physicians for Social Responsibility. I'm one of the groups that drove through the rainstorm this morning to get up here so we could express our concerns about what is going on. I'm going to limit it to the problems related to ground-based interceptors. The most tested but still woefully ill-performing technology to develop to thwart long-range ballistic missile attack is out of the midcourse interceptor.

This weapons system is designed to intercept enemy missiles in space from ground platforms in Fort Greely, Alaska, Vandenberg Air Force Base in Southern California. The chemicals used in solid rocket propellant that would be used to launch the intercept missiles, the test missiles and especially the booster rockets that place related detection communication satellites in space would all use imodium perchlorates as the oxidizing agent in the rocket fuel. The fuel would also contain highly toxic hydrazine compounds and nitrogen oxide. In the news of late, the developmental toxin perchlorate has been found in many of our nation's drinking water sources. This chemical inhibits thyroid hormone creation and release. In low doses, perchlorate is presumed to decrease the intelligence potential of a developing fetus. In cases of more severe exposure, can cause frank retardation. dditionally, once combusted and exposed to air moisture, perchlorates create hydrochloric acid, more commonly known as "acid rain."

Further, rocket launches deliver hydrochloric acid in the upper atmosphere which, in turn, chemically interact with the protective ozone layer. It is therefore fair to assume that an increase in rocket launches may correspondingly bring about additional cases of skin cancer. Rocket fuel needs to be continually replenished. The disposal of solid rocket propellant through washing out, propelling or open burning, open detonation are some of the major sources of perchlorate contamination across the country.

None of these perchlorate-related issues are adequately addressed in the PEIS. I'd like to add one further comment regarding the meetings that have been held. Southern California is bearing a disproportionate impact of missile defense development and its effects on the environment. The midcourse interceptor is being tested and deployed at Vandenberg Air Force Base in Santa Barbara County.

The Airborne Laser is being tested at Edwards Air Force Base in Los Angeles County. The space-based and Airborne Lasers are being developed by Northrop Grumman in the South Bay and San Juan Capistrano. Lockheed Martin, Boeing and Raytheon are deeply involved in developing the midcourse interceptors and other systems. At a minimum, there should be additional hearings near the areas most effected by missile defense developing. There should also be an environmental health evaluation concerning cumulative impacts for military production, testing and deployment of missile defense systems compounded on top of past military use. This evaluation should be done with an eye on disproportionate impacts on low-income communities of color. Thank you.

DC_PHO0026

Is this better? I'm Philip Coyle. I'm also from Los Angeles. The environmental process described in this PEIS is not believable or trustworthy because the statement read by Mr. Duke tonight is already not being followed. Mr. Duke said if testing failed to show the system worked, the system would not go forward. But as we know, the system is already being deployed even though it has no demonstrative capability to work under realistic conditions. To take a different example, the PEIS says and, I quote, The Airborne Laser is currently the only -- emphasize only -- proposed BMDS element with a weapon using an air platform, closed quotes. However, the PEIS does not discuss another proposed BMDS element that would use air platforms; namely, interceptors fired from aircraft.

With respect to the No Action Alternative already mentioned by others, it does not describe a scenario where no action is taken. Rather, it describes a system where the Missile Defense Agency would continue existing development and deployment unabated under the No Action Alternative. And I quote the PEIS here, Individual systems would continue to be tested but would not be subjected to system integration tests, closed quotes. This is hardly no action and allows for indeterminate missile defense program since -- to go back to quoting the PEIS, There are currently no final fixed architectures and no set operational requirements for the proposed BMDS, closed quotes.

Thus, even if MDA agreed to the No Action Alternative, it would not find its actions constrained for the foreseeable future. And, finally, with respect to space-based interceptors, the PEIS is silent about the fact that missile defense would, for the first time, weaponize space. While space is certainly militarized, it's not yet weaponized; that is, with attack weapons in space and with the chain reaction of a new arms race in space. The PEIS does not adequately address the environmental impacts of the consequences of placing strike weapons in space. Thank you.

DC_PHO0029

Thank you to everyone who has spoken so far. I think it's been -- I have learned so much and I feel like I really understand a lot more than I did when I came in. There is not very much really that I can add to a lot of the things that have been said because I don't have the particular expertise. I'm a local attorney concerned with human rights and peace. And so one thing I thought I might address is something that was alluded to by several of the speakers and that has to do with the process we're involved in here.

As an attorney, that is something we're always concerned about is process. At first when I first heard about the hearing and when I came here and saw all of the nice exhibits you had put up, my first impulse was this is really cool -- you know, this is really nice and how nice we've all been invited. But now I don't think so anymore because I'm noticing that there were only four locations at all where public testimony has been invited: Virginia, Sacramento, California, Hawaii and Alaska. That seems to me to be not nearly enough public input. That point has already been made.

I would like to talk about Exhibit ES-3, which is part of the Executive Summary. If you want to go along with me, that exhibit shows the effected environment. This is about environment that we're talking about here today. I looked at that to see what the affected environment was. All of the environment that can be affected is divided into nine biomes, as well a broad ocean area and the atmosphere. I went through that and I saw the following. I saw that we're talking about the Arctic regions, North Atlantic Ocean, Pacific Ocean, Alaska, Canada and Greenland. Then some more Arctic regions and also Alaska, deciduous forest and Eastern and North Western U.S. and Europe, Chaparral. That is California Coast, Mediterranean from the Alps to the Sahara Desert, from the Atlantic Ocean to the Caspian Sea. This is a lot of area here. And these are areas that are labeled as "affected areas." Oh, the Grasslands. That is the whole prairie of the Midwest. The desert. Oh, the arid Southwest. New Mexico, Arizona, Utah and the Rocky Mountains, as well as the Alps, Pacific Equatorial Islands, which I don't know. Maybe that is why we're going to be in Hawaii. Northern -- you've got to turn the page. Northern Australia. And then how about the broad ocean area. That has no particular latitudinal range and that's the Pacific, Atlantic and Indian Ocean. And then the really big one, the atmosphere, which is the atmosphere which envelops the entire earth. That looks to me like a global environmental impact.

And it seems to me only fair and some kind of rule that I think is codified in lots of different places that the people that are effected by legislation and -- and programs get to talk about it, get to respond. Well, that is going to be a lot more than the people in the U.S. Even if you say four hearings is enough in the U.S. -- this is a global environmental impact, this Star Wars Program. And, therefore, I'm not impressed with the hearing anymore. I think four is completely minimal. And so I would like to take the remainder of the time, if you would allow me, to make some suggestions of things that maybe other people might want to add, things that we might be able to do and do a little organizing here; which is, first of all, I think it would be entirely appropriate if you -- anybody who knows anyone and has connections, friends on legislation, which I'm a big supporter,

DC_PHO0029

lawsuits -- I think some lawsuits are called for for the reasons that were explained, which is the Environmental Impact Report is really inadequate and does not -- does not meet basic legal requirements.

I think that would be a very good thing to do. You should get ready for that and -- Colonel -- and another thing too is there are a number of people here representing different organizations, Physicians for Social Responsibility, FCL has -- there is also Friends Committee on National Legislation, different groups and so forth. Different groups. I think really we can get the word out through our emails and so forth about this.

And I'm also concerned about contacts in Europe for those like WILPF, for instance, which is an international organization or any international organization, Greenpeace, whatever, that you belong to because I think that people in Europe, Australia and so forth have a right to know about this and to have the same information that we have. And people may have other ideas. Now, just a little personal note here. My son lives in Southern Switzerland in the Canton of Tacino. He married a woman who is teaching. I'm going to let them know. I saw the Alps are in here. They're in the southern Alps. And I know that when I've gone to visit them, I can tell you those "pace" flags are hanging all over the place. People there really care about peace. They were part of a demonstration in Milan that was humongous. And I think there would be a lot of concern and there should be a lot of concern. I really think it's unfair to put a Star Wars system into place and not allow people who will be affected to weigh in on that matter.

And I guess my final suggestion would be to vote for change of Administration.

DC_PHO0032

My name is Winnie Detwieler. I'm here on behalf of Sacramento Area Peace Action and our 4,000 plus supporters, both to comment both to comment on the PEIS and register a complaint in which the manner in which the hearing has been scheduled. There's been no widespread publicity in California that we're aware of regarding this hearing today in Sacramento. Is this some sort of the stealth strategy to limit public input on such critical issues. The question is: Can the Draft PEIS be legitimate if there is not adequate notice of the document in the hearings on this matter?

What is most disturbing, however, is that the current Administration is forging ahead with components of the first two interceptors for the BMDS, making a mockery of these hearings. It's even more perplexing that the interceptors were just installed and had not been tested in the system. The tests have been continually postponed and the Pentagon's Chief Weapon Evaluator has said the interceptors may only be capable of hitting their target about 20 percent of the time.

Why is our government spending billions of dollars in risking the beginning of a nuclear arms race on a so-called missile shield with such an abysmal record? The greatest danger we face is not some intercontinental ballistic missile carrying nuclear warheads to our shores; but are reigniting nuclear arms race and motivating countries that fear us to attempt illegal acquisitions of nuclear weapons. They see the technology for our Missile Defense System can also be used offensively against them. Their defense against our military superiority would be to either produce many nuclear ballistic missiles to overwhelm our 20 percent system or to use secret delivery system weapons smuggled into our country or delivered by short-range missiles launched just off shore.

Forging ahead with the missile defense system will create terrible consequences from pollution from rocket launches, space debris and accidents within the system or involving civilians. Other groups are scheduled to testify more comprehensively on this environmental hazard. But I'm emphasizing here all people on Earth, not just Americans, face grave environmental threats from this drive to dominate the world by dominating space.

The environmental pollution may kill us slowly if we don't do it quickly with a nuclear war. But the greatest environmental impact will be to make the entire planet more dangerous to all forms of life and we Americans more vulnerable and not safer. Most Americans consider nuclear war unthinkable; but apparently our leaders in Congress do not. It is astounding to see the turn around on proliferation and new nuclear weapons in this Administration. Will threatening other nations encourage them to cooperate with a non-proliferation treaty? Will the U.S. violations of the treaty persuade other nations to embrace non-proliferation? We think not.

Similarly, the abrogation of the Anti-Ballistic Missile Treaty last year by this Administration in order to pursue this fantasy missile shield will not promote international cooperation on disarmament. We can only conclude that this rush to further

DC_PHO0032

develop and deploy this ill-conceived missile defense shield is driven by ideology and politics and fueled by the greed for profits from this costly boondoggle. That is what it is, a boondoggle. The leading scientists and Nobel Prize Laureates have condemned this as irrevocable and dangerous to global security. But this Administration rushes headlong into a hasty deployment. The term coined to characterize this drive is a "rush to failure."

In conclusion, we at Sacramento Area Peace Action condemn the Alternatives 1 and 2 with extreme threat proposed on our nation and the world. We would support the No Action Alternative if there had been a legitimate attempt at researching and weighing a true alternative of no action. Such a proposal should have encompassed a suspension of research and development, no testing and no initial deployment. It should have evaluated the cost effectiveness of vigorous pursuit of international cooperation on nuclear disarmament.

As it stands, the No Action Alternative does not meet the requirements of the National Environmental Policy Act. For this reason, we consider the Draft PEIS inadequate and insufficient for proceeding with the BMDS.

DC_PHO0037

Hello, my name is Jean Bodeau and I have no affiliation with an organization. I'm a professional geologist and engineer and I've worked as an environment consultant in Alaska for almost 20 years. I now work in health care. Some of the work I've done as a consultant is I've managed several million dollars worth of military contracts, mostly for the Air Force. I oppose the entire program on both philosophical and concrete grounds, with specific points as follows:

First, it doesn't address the real threat, i.e., terrorist with low tech devices that could come over borders, by sea, suicide bombers. I understand the Iraqi insurgents now are trying to get more weapons of mass destruction. This project, to me, seems totally divorced from the realities that we're facing as a country and takes funds away from the real threats.

Two, the sequencing on the whole program seems backward. The EIS is late and the project is premature. Furthermore, the technology doesn't appear to work, yet it is already being deployed.

Three, NEPA does not seem, to me, to be a big enough vehicle to evaluate the program. It should include international input because the implications of this project are global. And I noticed on your map out there Antarctica is not included on the map. I'm sure you looked at it but.....

Fourth, the PEIS, with all due respect, I know a lot of work went into it, is -- in my opinion it's crap. I've worked on these things quite a bit and I know that you can manipulate your data, manipulate your analyses to come out with exactly the results you desire. And I think that's what's been done here. It ignores or glosses over potential concerns and it put many other assessments off to future assessment to the site-specific assessments, the tiered impact -- or the tiered assessments that you mentioned.

I noticed on the summary and in the documents, I've looked through those. I got them in the mail and I appreciate those being sent out in advance. There are a huge number no significant impacts listed. And I think that this issue is a big enough and hugely important issue that it deserves more than a cursory analysis of the environment impacts.

I have some more specific concerns, things that the PEIS does not adequately address. Number one, exposure to increased levels of toxic pollutants from a dramatic increase in missile launches. Liquid propellants containing hydrozene, nitrogen tetroxides and other compounds that are highly toxic. In addition, ammonium perchlorate, which is used in solid propellants, it blocks the formation of key thyroid elements that are critical for growth and development, especially in fetuses and children, and this was not considered. Another concern is that the risk to health and safety of DMD missile accidentally shooting down civilian and friendly military aircraft was not considered.

Third, it neglected to look at space debris from high altitude midcourse missile intercepts or destruction of satellites, and it really glossed over potential impacts of debris falling to

DC_PHO0037

earth. It just wrote them off as being burned up in the atmosphere. Another concern is that it didn't really look at the many rocket launches that are needed to test and deploy and maintain the space interceptors.

Five of the specific points, the program could contribute to the proliferation to the weapons of mass destruction and an arms race in space. The response of other nations to the BMDS has not been considered.

Six, radioactive fallout from intercepted missiles has not been considered. The effects of war are normally excluded from analysis by NEPA; however, this proposed BMDS action is very likely to provoke a worldwide WMV arms race and force other nations to prepare to launch a massive retaliation against the U.S. should war ensue. And I believe that radioactive fallout needs to be looked at and not written off as a no significant impact.

Seven, also missing is an assessment of impacts to the environment, human health and welfare and future generations, which would result from the monstrous financial burden of this program and taking resources away from other critical aspects of our nation.

And, last, the BMDS PEIS does not really include a No Action Alternative. Your No Action Alternative does not include the option of not deploying any of these, there's just dropping the program right now. And I think that we need to have a true No Action Alternative considered as part of this.

I am going to submit additional written comments. Thank you for the opportunity.

DC_PHO0038

Hi. Thanks for having me. My name is Steve Cleary, I'm the Executive Director for the Alaska Public Interest Research Group, my acronym is AKPIRG. That's another acronym for everybody tonight. I, like Jean, am in favor of the No Action Alternative, but would also like a real No Action Alternative, which would save us tens to hundreds of billions of dollars if we didn't deploy the system.

I remember from last time, part of about the radar, somebody from Valdez was worried about that it was going to set off airbags in cars, set off fire extinguishers, some kind of weird effects of the radar, but I didn't see any mention of that in there and I didn't get a chance to read the whole thing. I just read the executive summary. So I would like to hear more about that.

But I think a lot of us are concerned about the integration of all these systems when all the systems aren't here. We hear about the sea-based radar that's going to be swung around and come on up and be sitting outside by Shemya, but we have five missiles in the ground, maybe six by now, and we're going to start deploying that by September, but yet this isn't due until -- you know, the Record of Decision isn't going to be until February, so the integration of the system doesn't seem to have happened, yet it all seems to be going forward and this Programmatic EIS doesn't seem to have a whole lot of effect on that.

So, again, I am here tonight to speak in favor of the No Action Alternative. I do also believe that deployment of the missile defense would spur a global arms race and cause nations to devote resources, simply because we are, to this weaponization of space.

I'm also concerned that we'll be exporting it to non-U.S.A. locations, Canada, United Kingdom and other places who might see us as a world superpower and want to, you know, receive our favors and so they would acquiesce to this system. Specific to Alaska, I have a lot of questions about the Kodiak Launch Complex. I'm really concerned about the aborted launch that happened at Kodiak, I believe it was two years ago November and Kodiak itself is a significant enough population center to be concerned about it, but if we start launching missiles from Fort Greeley, which is near Fairbanks, near Delta Junction, that have to be aborted, there's significant population centers there, not to mention the TransAlaska Pipeline.

Something that was mentioned in the presentation and in the PEIS, it talks about a robust testing program. It mentioned in the PEIS that the test are going to dictate which further things happen. We haven't seen a realistic test yet and that concerns us here in Alaska, particularly when, you know, like I said, an aborted launch could have such a disaster effect on our state.

It's unclear from the PEIS, and I'm looking at Section 2.242, whether or not the Kodiak Launch Complex is going to be a launch test and defensive operational asset or if it's going to launch things into orbit, or if it's just a test center. So it's confusing for the folks on Kodiak and for us here in Alaska what is actually going to happen out on the island.

DC_PHO0038

It talks about a safety zone that would be established around the laser during activation. This is also in the PEIS, Pages 250 to 254. There's a lot of small plane traffic and a lot of small boat traffic around Kodiak and other places in Alaska. It has us concerned about the laser and its effects on our economy and on the human resources, or humans, I should say, of Alaska.

The hydrozenes that Jean mentioned were the same things that I believe came from when the space shuttle crashed and landed in Texas and there was a very large mobilization to get people not to touch those things. And if that's the same chemical that's going up with each of these launches and potentially coming back down, then those will be grave consequences indeed. A lot of the missile defense system has been sold up here in Alaska for the economic benefits. And I know the Programmatic EIS also takes in social and economic benefits and I could think of a lot better ways for us to spend these hundreds of billions of dollars that will eventually be spent on this system that isn't going to work and is also addressing the least likely treat.

So I thank you for the opportunity to speak in favor of the No Action Alternative. Thanks.

DC_PHO0039

Yes, hello. My name is Greg Garcia, I'm a member of Alaskans for Peace and Justice, as well as No Nukes North. There's just a few brief things I'd like to say about this. I mostly want to comment on it as a policy issue. I realize that, you know, the purpose of this is to take testimony about the actual environmental impact of this and I'm not really all that knowledgeable. I've looked at a lot of the materials about it, about the environmental aspects and, frankly, you know, I'm not probably qualified to interpret a lot of the things that are said there.

However, I do definitely oppose the space-based weapons platform that are mentioned in Alternative 2. Certainly, you know, be opposed to putting weapons in space. I'd like to see something quite a bit less than the No Action Alternative, I'd really like to see something rolled back in a way and dismantling and using these resources, the financial resources that were wasted on this on much more pressing needs in this country.

As many people have mentioned, it does protect us from what's the least likely attack scenario. There's way too many other things going on that are threats where the resources that are being expended here could be used. For example, roughly four percent of the cargo containers coming into the United States from foreign countries are inspected in anyway, and that's mostly just inspecting the paperwork, not even actually doing an actual physical inspection. And we could certainly create a lot of jobs that way, as well as by building this system. So it doesn't seem like a very good cost benefit there.

I feel that this system makes us less safe. In one way by leading to an increased arms race as we have pulled out of the 1972 ABM treaty. I think that was a mistake. By pulling out of that treaty I think we've stimulated China to increase its production of intercontinental ballistic missiles and possibly the spin off there is that India and Pakistan may be increasing their weapons as well in order to have a defense against China.

The idea to dominate space seems to be at the heart of this, that's fairly, clearly spelled out in United Space Command documents and this seems to be kind of a component of that. And it would seem to me that the desire to dominate space is just a new era of colonialism. In conclusion, I feel that this entire system is based on corporate welfare, that the legislative process that takes place in Washington, D.C. seems to be dominated by huge multinational corporations that want to build the system and so they have managed to lobby and provide the funding for the campaigns for the Congress people, Senators and Representatives who have approved for this program to take place, so that they get to become even more fabulously wealthy than they are now by building a system that, frankly, doesn't work. Thank you.

DC_PHO0044

MICHAEL JONES: I have a few comments to make about deficiencies in this, and some of these were deficiencies in previous analyses.

There's no examination of treaty restriction on target launches in this EIS, no quantitative information on the liabilities of rocket boosters. There's some inconsistencies and confusion about cumulative impacts. This EIS estimates 515 launches in a ten-year period, the previous 2003 ground-based missile defense extended test range EIS estimated only 100 in a ten-year period.

There's an egregious error in Exhibit 4-11 on page 4-102. First of all, there's an addition error in the table. The more serious error is that total emissions for the interceptor are given as 115 kilograms, whereas the 2003 EIS for the ground-based interceptor gave the first stage emissions as 15,000 kilograms. So what's given in this EIS is a factor of 100 too small.

Probably the most serious problem is that this document is largely irrelevant.

As the summary in Section 1.2 indicates, environmental analyses have been done for most of the components already. Notable exceptions are sea-based midcourse defense and space weapons, which to my knowledge have not been analyzed.

R&D and testing of most of the components is well underway and decisions have mostly been made

about these systems, including even decisions about the initial deployment of the ground-based midcourse defense and the sea-based midcourse defense.

The No Action Alternative is not seriously considered. It is claimed not to be at the direction of Congress, presumably the 1999 Missile Defense Act. This Act states U.S. policy is to deploy as soon as is technologically possible an effective NMD system, but the EIS has no discussion about NMD effectiveness and whether that criteria is satisfied.

Finally, the spiral development approach seems to preclude any meaningful assessment. The PEIS could make an useful contribution by analyzing how to judge the effectiveness of the missile defense with no specified architecture and no operational requirements.

Thank you.

DC_PHO0045

ELAYNE POOL: I have a letter that's been signed by 36 people and myself and I would like to read that to you, please.

We support a real No Action Alternative to the deployment of a missiles defense system. This means no further testing, development or deployment.

Deployment of such a system threatens a new nuclear arms race, puts the global environment at risk, and does not improve the security of the United States.

Deployment of a missile defense system will increase the likelihood of a nuclear catastrophe. It impels Russia to maintain a larger nuclear arsenal on high alert than it otherwise would.

Deployment also drives China to deploy a larger arsenal. The impact of a nuclear war, whether accidental or intentional, would dwarf any other environmental nightmare one can envision.

Moreover, the system does not improve our security. So far it has yet to be tested in realistic

conditions and would be ineffective against an attack.

While in the future the capabilities of this system can be expanded at great expense, these developments are likely to be made useless by the newly improved weapons and countermeasures of potential adversaries.

Finally, the $10 billion a year being spent on missile defense should be spent on measures that are more effective and environmentally sound. One example is the program to secure stockpiles of nuclear weapons material in the former Soviet Union and other countries.

The testing, development, and deployment of the missile defense system should be halted, given that the system leads to environmental harm and potentially to environmental devastation and does so without improving the security of the United States.

Finally, I'd like to read a statement, and I wonder if you know who said it. These words certainly apply to this costly system that is untested and will endanger mankind further.

"Every gun that is made, every warship launched, every rocket fired, signifies in the final sense, a theft from those who hunger and are not fed, those who are cold and are not clothed.

"The world in arms is not spending money

alone. It is spending the sweat of its laborers, the genius of its scientists, the hopes of its children.

"This is not a way of life at all, in any true sense. Under the cloud of threatening war, it is humanity hanging from a cross of iron."

That was said by Dwight Eisenhower, Five Star General of the U.S. Army and the United States President.

DC_PHO0046

KYLE KAJIHIRO: Aloha. I am Kyle Kajihiro. Thank you for this opportunity to testify. I am representing the American Friends Service Committee this evening, Hawaii area program, and we're opposed to the Ballistic Missile Defense System completely.

I think that you have inadequate alternatives. You only have three alternatives and there ought to be a fourth one which includes not deploying, developing the Ballistic Missile Defense System, and actually reducing the scope of existing programs.

That should be considered as a real alternative for considering what is really in the interest of the United States and the world in terms of building a real security environment.

I want to first just go back to the question of the process being flawed so it can get on the record.

Again, I think that these processes have typically discouraged public participation. Whether that's by design or just by negligence, I think that it needs to be noted that there haven't been adequate efforts to reach out to the public, to provide accessible venues and opportunities for people to testify.

As I said earlier, as Terri Kekoolani said earlier, Hawaiian translation is essential, the native

Hawaiian language, Olelo Hawaii, is one of the official languages of Hawaii, and that should be honored in these proceedings so that when Hawaiian words are expressed, they are captured correctly and not noted as inaudible or unintelligible, which is often the case.

Second, the question of native Hawaiian culture being an oral tradition, it's very important that you provide opportunities for people to give live testimony where they can look you in the eye and express what they are feeling.

When you say that often written testimony or e-mail testimony is adequate, you effectively discriminate against a whole group of people who are actually one of the groups that are disadvantaged and should be considered as part of the environmental justice analysis of your Environmental Impact Statement.

The missile defense program we believe violates international treaties and is destabilizing in this global environment. As others have said, it will increase the likelihood of nuclear catastrophe by creating nuclear rivalries and forcing other countries to build up their arsenal.

In July 2001 the Russian foreign ministry spokesperson, Alexander Yakovenko reacted very angrily to the U.S. missile defense tests over the pacific. He warned that the missile defense

contributes to a situation which "threatens all international treaties in the sphere of nuclear disarmament and nonproliferation which are based on the 1972 Anti-Ballistic Missile Treaty."

On June 13, 2002, George W. Bush unilaterally and without the vote of Congress withdrew the United States from the ABM Treaty.

So I think that if the United States is going to be a leader of the world in terms of establishing policy for peace and democracy, it needs to demonstrate that by its own actions, and instead it's only demonstrated a policy of aggression.

The nuclear posture is now to consider the possible use of limited nuclear strikes. That's a very dangerous step from past nuclear doctrine, and combined with the missile defense system is seen as a threat to many countries around the world.

So I don't think you can separate the missile defense system from the rest of the nuclear doctrine. It has to be considered together. And in that light, missile defense is an offensive weapon, as others have said, to establish U.S. full-spectrum dominance.

So the Programmatic EIS fails to analyze how the proposed BMDS system will affect the international security environment, how will it impact international laws and treaties such as prohibitions on the weaponization of space. And that's one of the explicit options for the Ballistic Missile Defense

System. So that goes against established agreements to keep space for peace.

I want to also speak about the opportunity costs. As someone testified earlier, what we spend on missile defense and other military spending is stealing from the dreams of our children, the potentials of our community.

I want to give you an example of how this would affect us here in the Hawaii, according to the National Priorities Project. Taxpayers in Hawaii will pay 33.1 million for ballistic missile defense in fiscal year 2005.

For the same amount of money, the following could be provided: 11,269 people receiving health care, or 4,426 Head Start places for children, or 17,466 children receiving health care, or 150 affordable housing units, or four new elementary schools, or 9,556 scholarships for university students, or 571 music and arts teachers.

So I say that that needs to be considered. The opportunity costs of ballistic missile defense is one of the impacts that we have to deal with and our children have to deal with, and it needs to be considered in your Environmental Impact Statement, and I didn't see it listed there.

The cumulative impacts analysis I think was very flawed. You said earlier that you would only consider similar types of global actions in comparing

what the cumulative impacts would be, but I think that's a way of effectively ignoring the combined effects of many, many local impacts that occur when you have these programs in many forms around the world. So I think you need to consider all those analyses, the local studies that are being done, that have been done, past, present and future.

And this also includes historical impacts related to colonialism. As others have expressed about the Marshall Islands, the U.S. program there has been devastating for that community. The same is true here in Hawaii for native Hawaiians; the 111 years that the U.S. military has invaded and destroyed Hawaiian land, culture, or denied people the ability to practice. Those also have to be considered as part of the cumulative impacts.

And this gets to the environment justice analysis, which is also flawed and inadequate.

There is an adverse and significant impact on native peoples here in Hawaii, in Greenland, Enewetak in the Marshall Islands, and in other places, Alaska and so forth, and you did not look at how this program has a disparate effect on those peoples, their culture, their resources, and actually their survival. So please consider those.

And, in closing, I urge you to scrap the program. We oppose the ballistic missile defense, it's dangerous, it's wasteful, and the world will be much better off without it. Thank you.

(Applause.)

To add a little levity here to this program: It's been documented that the program is -- the missile defense system is easily fooled by decoys which resemble these mylar balloons in space, and because there's been so much, I think, misinformation or incorrect information about what the program actually is, we wanted to present you with this testimony that sort of documents some of the effects.

DC_PHO0047

ELMA COLEMAN: I'm from the Marshall Islands.

(Applause.)

MR. BONNER: Yes, absolutely.

ELMA COLEMAN: (Speaking Marshallese.)

51 years since the nuclear Bravo exposed the people of Marshall Islands to nuclear fallout.

(Speaking Marshallese.)

The people did not know what was happening. They didn't know how to deal with the nuclear fallout.

(Speaking Marshallese.)

Are they aware of what would they do if there's any accident with the missile testing?

(Speaking Marshallese.)

Conduct one hearing in the Marshall Islands. After all, that's where the missile testing is taking place.

(Applause.)

How come I'm reading here that the request was given to have the hearing posed or made on Kauai, Maui, and the Marshall Islands, and it was refused? These are the most affected places that are going to be most impacted.

(Speaking Marshallese.)

I don't think that's fair.

DC_PHO0047

(Speaking Marshallese.)

Or at least reassure the people that there's not going to be any accident happening. But we cannot say that there's not going to be any accident. There's no guaranty. No matter what, there's no guaranty. And if something happens, what are the people going to do?

(Speaking Marshallese.)

You know, I'm not sure what kind of chemical you use or you put in a missile testing or in the warhead when you intercept it in space, but all over the years that you have been doing the testing between Kwajalein and Vandenberg, has there been any environmental study of all the debris that has fallen down into the ocean to find out how contaminated the area is and how far spread the contamination is? Has there been anything done like that? And have the people been aware of what has been done or has not been done?

DC_PHO0048

MARTI TOWNSEND: Aloha kakou. My name is Marti. I have a few points to make. The first are mostly legal, because I hope to God this EIS is put through litigation.

First, notice and public hearing were inadequate. Although it's true that NEPA doesn't require them to hold a public hearing, it does require that the notice be on par with the extent of the program. And as they've clearly shown on their beautiful screen, this is supposed to have worldwide effect, yet we're only having, what, thirty of us here? I mean, this is affecting not only all of Hawaii, but all of the pacific and all of the entire world, and where was this hearing noticed in? Was it noticed on TV? Where did you guys hear about it? Word of mouth. I don't think notice was sufficient in this case, especially given the extent of this project.

In addition, as everyone has stated, there should be more hearings held. The three on the continent and the one here are just not sufficient.

In addition, the alternatives analysis is also inadequate. NEPA requires the alternatives to be considered, including the No Action Alternative, as has already been stated. That is sorely inadequate. But, in addition, you'll notice from reading the two alternatives, they're simply variations on a theme, they're one and the same thing.

DC_PHO0048

And the reason for this, the reason why this is justified is because they're getting off on a technicality, because they stated that the purpose of this program or this project is to implement a Ballistic Missile Defense System. It's misleading, because really what this project is supposed to do, like the overriding principle, is to provide for the defense of the United States.

If you're going to provide for the defense of the United States, you need to talk about what are some real practical things that we should do or that Americans should do to protect themselves, and that includes, you know, not going over to other countries and blowing them up. We're actually talking about real diplomacy.

Unfortunately, this EIS doesn't do that, so, therefore, it's inadequate. I'm hoping that through litigation the technicality, like, can really narrowly define the purpose so that you don't have to do an extensive alternatives analysis, will end with this PEIS.

Also, the cumulative impact analysis is also inadequate. NEPA requires that past, present, and future activities that may incrementally add up to accumulative impact on an area be assessed, but this PEIS is flawed for several reasons. First, it doesn't really consider past projects in the cumulative impact analysis. It says something to the effect of, well,

there are things that had gone through NEPA assessment before and so we're not considering those now.

This is obviously logically flawed. I mean, the EISs that we've gone through before, had any of them ever dreamed that there would be a missile defense thing shot from space? I mean, let's look at the Striker IS. We're all familiar with that. Does that mention at all anywhere ballistic missiles? No.

Okay. So clearly relying on a NEPA document published before this day is not going to give us an adequate analysis of whether it's a cumulative impact. In fact, there's a heck of a lot going on here caused by the military that never went through NEPA analysis.

Let's talk about use of Agent Orange on Oahu, okay? There's lots that needs to be assessed here, and to just cop out and say, well, there was once a NEPA document done, when we never even dreamed of shooting missiles from space, that's just not going to cut it.

In addition, they also put this really interesting limitation on it that I've never seen before in an EIS, and I've read quite a few myself. It says, well, because this has a national and international nature to the impact of the ballistic missiles, they were only going to consider national/ international cumulative impacts. That means only something that affects the entire continent, only if

it affects the entire world. So we're not going to look at the unique situation of Hawaii. And what we are having to go through is the increasing militarization of Hawaii, and that's not sufficient.

I mean, to really consider the cumulative impacts of this PEIS, we need to talk about things that are in the areas that are likely to be affected and likely to be caused harm.

In addition, the PEIS -- I guess I covered that point. Okay.

So the two main points are that past analysis is needed, we need to look at previous things that have been done in Hawaii and across the country or across the United States that have caused impacts, and then also the effect of not just national/ international impacts, but also of local impacts.

The rest of what I have to say is really like a wake-up call for people. Like I said, there's only what, thirty of us, maybe forty? This thing is huge. We need to not let them take advantage of our trust, take advantage of our naivety. We need to get out there and talk to every person you know about this. This is huge. The only way that we're going to counteract this is not through these public hearings -- they are a great way to educate ourselves and connect with each other -- but what we need to do is talk to your Congress people, talk to your neighbors, vote, demonstrate, write letters to the editor,

educate people about what they want to do.

Crap is going to fall from the sky. It's going to set on fire and it's going to land on the ground. They're going to be shooting hazardous materials from space. And CERCLA is mentioned once in the EIS. CERCLA is the hazardous waste law. Want to know where it's mentioned? In the table of contents, that's it. It's only mentioned in that list where they say, these are what all the abbreviations are. It's not anywhere else in the document.

So we need to organize. They really are playing on our trust and our ignorance about this process. They say stuff like, well, there's no unavoidable adverse impacts. I think Marty said something to the effect there's no, like, showstopper environmental impacts. Well, that's because they are relying on a thing called best management practices.

Best management practices says that given whatever project you're involved in, you use the industry standard to make sure that you are abiding by whatever everybody else is doing. So if you're running a power plant, you look at what other power plants are doing and make sure you are doing the best thing environmentally for that.

Well, let's see. Who else is shooting missiles from space? Don't know. There's only one. Okay. So best management practices is whatever they

want them to be.

So there are going to be unavoidable adverse impacts. We can't let them string us along like that. They use these words and these technical terms and people don't know what they mean. This stuff is just filled with technical jargon and we're forced to read 500 pages and make an informed decision about something.

They are using this process to sort of tell people who don't think we have the time to get involved because we're too busy being employed and trying to raise a family, they use this process to cover up the fact that we aren't really making an informed decision, that people are being taken advantage of, and the law is being tweaked and used to their advantage to disempower us.

So although they may meet technical requirements of NEPA, we need to make people aware of the fact that they are not meeting the real requirements of NEPA and we aren't making an informed decision. Thank you.

JULIA ESTRELLA: Good evening. My name is Julia Estrella and I serve on the National Committee of the United Church of Christ which deals with justice for Micronesians. It is with that hat on that I testify before your committee tonight.

As a member of the Micronesian Pronouncement Implementation Committee of the United Church of Christ, I have become aware of how the United States tested 67 nuclear bombs in the Marshall Islands from 1946 to 1958.

Now the United States' missile plan includes missile launches from Vandenberg Air Force in California to the lagoons of the Marshall Islands.

I am not a scientist, although my husband was a physicist, and therefore I do not understand all the scientific terminology that they use in the EIS. In fact, as I was listening to all three of you make your presentation, I felt like I was an alien from another planet, as though -- I mean, we were totally in a different stratosphere as far as I was concerned. I felt pretty overwhelmed by your presentation and, actually, I began to feel like how the Marshallese folk must have felt when the military approached them and asked them to give up Bikini. I felt like you were saying this is good for mankind, trust us, we know what we're doing, and feeling overwhelmed. You know, I felt like I was being fooled. I felt like the decisions were already being made. How can you say no

when probably the decisions are already made to move in this direction?

Anyway, I feel that I was glad to hear the previous speakers all talk about cumulative effects, because I think that is one of the weakest areas of your EIS. The cumulative effects on the Marshallese people, for example, who have already been exposed to so much nuclear poison and now you want to add more toxic waste into their lagoons. And the cumulation, the additive factors, I think you have not even touched on how this is going to impact a group of people that have already suffered enough for us Americans.

So I think that if we're going to shoot at all, we should be shooting these missiles on the coast of Washington, D.C. I think that would be more fair in terms of cumulative effects on a group of people who have already taken too much of our nuclear and our toxic waste into the lagoons.

Also, I feel that instead of spending billions on an expanded missile defense program, I, like Kyle from AFSC, feel we should spend those billions on the needs of the people.

I work with people who live in public housing, as an organizer, and I see the people on a day-to-day basis who don't have enough food to eat, enough supplies for schools, who are on a survival basis. And here we're speaking about spending all

these billions of dollars for what? You know, to me it's such a big waste of money, a big boondoggle. And who is benefitting from it? All the big defense contractors like Rayon and all these multinational corporations. These are big bucks for the military contractors.

It's not fair, it's not just, and I think we need to realize that. Even in the EIS, we need to state something more clearly about the social impacts and what it does to ordinary people who do not benefit from these kinds of programs. The rich are already getting richer. Why put more money into the pockets of these defense contractors?

Then, finally, I wanted to say that in your EIS I think you're misleading all of us by putting No Action as a third alternative. I think you need to be more honest and state specifically that No Action means to keep on testing as is without the integration.

I think that some of the people here felt like No Action meant that you were going to start dismantling the missile defense system, which, of course, should have been stated as another alternative, which you didn't even give us a chance to put down.

At first I was going to put No Action, and then I read where it says continue testing as is. And so please do not mislead us. Please state what you're really meaning when you say that's a third

alternative. And please give us another alternative which says stop Star Wars, dismantle the missile defense system, start helping the people who really need the help, and let's bring peace instead of more destruction. Because as you were talking, you talked about destroy this and intervene here, and we don't need more destruction. So in the EIS please focus on other than destruction.

Thank you.

RON FUJIYOSHI: My name is Ronald Susumo Fujiyoshi. I come here as a member of U.S. Japan Committee for Racial Justice. I also served as a missionary of the United Church of Christ for 29 years. Twenty of the years were in Asia. And after that, part of the time was in the pacific.

A friend of mine, Dr. Kosuki Koyama wrote a book called "Water Buffalo Theology," and one of the chapters of the book was called "Gun and Ointment." He said that western imperialism has gone and colonized the world, and in many cases the missionaries were the ointment that went along with the gun. And since I was a missionary, I wanted to state very clearly that we need to cut the ties of the missionaries, the ointment that goes with the gun, and to state very clearly that we oppose any gun.

So that's part of the reason why I am here today. I think the EIS or the Draft EIS that I read is just a shibai. "Shibai" in Japanese is something like a show, just a show or a play or a deception. You know, all of the nice PR stuff that is written and says there's no impact, we know there's an impact because we know Marshallese people are dying of cancer. We know that the Department of Energy is cutting back the funds that are monitoring the Marshallese from the atolls of Rongelap and Utrik because of the expense and the war in Iraq.

These are the ones who were used as guinea

pigs in the 67 nuclear and atomic tests. The cumulative effect of the 67 nuclear and atomic tests were 7,000 times the impact of the Hiroshima A bomb. You can't imagine what 7,000 times Hiroshima is.

Seiji talked about coming from Hiroshima, so he has seen firsthand the effect of just one A bomb on Hiroshima, and so it's beyond the scope of us to imagine what 7,000 times that would be.

I went to the Marshall Islands maybe about five times when I spent time there, and the last time I went was on March 1st of last year, which was the 50th anniversary of the Bravo test, and we were there with the survivors and heard their stories of that one Bravo test, which was the first U.S. hydrogen bomb tested. And so we heard the stories of what happened in the tests. And to me it's very hard for the Marshallese people to believe the U.S. military, especially in cases like the EIS, because, as Elma explained, if you looked at the video called "Half Life," you would see that there was a U.S. Commodore Wyett who went and spoke to the Bikini Marshall Islanders after they came out of church on Sunday and he made a statement that you can see for yourself in here that they're going to harness this destructive nuclear force for the good of mankind, and he asked them, will you give permission to move off the island so we can do this for the sake of all mankind. And their response was something like, well, if it is the

will of God, we will do it. And so he made the statement, and I can't forget his statement, well, if it is the will of God, it must be good.

You know, and that kind of a shibai or deception has gone down through the ages.

Many of you know that in 1972 Secretary of State Henry Kissinger confirmed U.S. thinking that American military interests must prevail over the self-determination of the Micronesian people when he casually remarked: "There are only 9,000 people there. Who gives a damn?" This was quoted by former Secretary of Interior Hickel.

So I think if you are Marshallese, are you going to believe an EIS statement that says no impact? I think it's very hard to convince them that there is.

I think those of us who are from Asian or Pacific background, we have a theology that all life is related. What is related is a harmony of life, so that what you do to one thing, affects everything else. But it's only a western kind of thinking that compartmentalizes everything and says, this spot will have no impact, this spot will have no impact, this spot will have no significant impact, this spot won't have, and then they go around the whole thing and say, therefore, there's no significant impact. Well, we know that's erroneous, because the whole understanding of how everything is interrelated is different from that. And I think we need to point that out to the

people here.

We had Joanne Whipplejuwski (phonetic) of the PST (phonetic) who was the managing editor of the Nation Magazine, went over to the Marshalls and did an in-depth story. And she went to Roy Nomura (phonetic) where some of the top U.S. military scientists are stationed. It's way in a secluded area and many of them are brilliant people because they are tracking the missiles. And they said that this is like a bullet striking a bullet. It's impossible to do. It's impossible to do.

And so what they do actually is they put homing devices in the missiles so that they can have a chance of hitting the missiles. If they didn't have that, there would be no way they're going to do this. So here they're spending billions of dollars on Star Wars when the chances of success are so minute that it's wasting of money.

I think we should be using the money not no make war, but to build friends. And I think what it has to do with, places like the Marshall Islands, is to care for those who are affected by the 67 nuclear and atomic tests, and that's how you keep from having war. I think you build friends.

MR. BONNER: Could you finish up, Mr. Fujiyoshi, or come back?

RON FUJIYOSHI: Okay. I think what is happening is there's no transparency. So much of the things are done in secret that we don't know what is

really going on.

I was arrested twice on Kauai, PMRF, when we tried to oppose the missiles being fired from Kauai to Kwajalein. Why? Because pacific people are now firing on pacific people. And so it's being fired from a burial site on Kauai. And one of the things we found out in one of the times we got arrested is that foreign, other countries, are using missiles to test their own missiles, too. And what do they use in the payload, that was secret. We couldn't find out what was it.

So all of the things that we're doing, we're trying to guess, because we don't know. They're asking us to believe them when there's no transparency. And we need to find out what is really going on.

For example, I read all of the material out there. I don't even see the word "depleted uranium." And depleted uranium is so crucial even right now, what is happening in Iraq or elsewhere, you know, people, even our own soldiers that went in Iraq in the first war, you know, were affected by that. I went to Vieques, and we know the effect of depleted uranium upon the people there.

So if they're not even mentioning depleted uranium in the material on here, then what else are they keeping from us? I think we have a hard time believing that what is being done is on good faith.

DC_PHO0050

Finally, I think if it's true that the Missile Defense Agency refused to have public meetings on Kauai where PMRF is and in the Marshall Islands, to me that's a very deep flaw. That's something that needs to be corrected. So I support stopping of Star Wars. Thank you.

DC_PHO0051
TERRI KEKOOLANI: Aloha kakou. Kala mai ia'u.

I'm going to turn my back to you folks. I want to talk to these guys.

I just want to make a few comments. First of all, the first comment I want to make has to do with the process. It is very deeply flawed. If what you are planning goes through, then obviously all islands will be impacted. Therefore, to properly inform our people here in Hawaii, you must have all people from all islands being fully informed, which would include the Big Island, Maui, Molokai, Lanai, Ni'ihau, and Kauai.

And it's amazing to me that you don't have a meeting scheduled in Kauai with almost half of an island impacted by the missile range facility there.

Also, just alone coming on Oahu, you're having a meeting in a very small hotel, in a small room. The capacity of the room is sixty people. And so what it looks like is that you're kind of hiding, and that you are not looking for a way to actually get a lot of people to participate in this process.

So what you're doing is actually minimizing the input of people, but you sure are maximizing the hardware that's going into this plan of yours. So I think this is a very, very, big flaw.

Also I would like to say that I just returned from a visit on the island of Ka-ho'olawe and I mentioned to people who have been visiting from

Kauai on the island that this hearing was taking place here on Oahu, and they didn't know about it. I don't know if you guys know how much it costs to get from Kauai to Oahu, but it takes some money, and our people don't have that kind of money. So it says something about you. It says something about how you folks think, that you don't have our people included in this process.

The second thing that I would like to talk about is five minutes. How long did it take you to put this study together? You all only give us five minutes to comment. I don't understand that.

The other thing is, that's not island style. It takes us maybe kind of like a couple of hours just to say hello, just to get to know you. Like who are you, where you from, why are you here, what's on your mind, what do you want to do? What is going to happen with the plans that you are going to do to us? How is it going to impact us? That takes a long time. I mean, come on.

The other thing is, and people have already commented that you don't have any person here that can translate our language. And I'm glad Ms. Coleman spoke to you in Marshallese. You need to do your homework. Before you come to the islands, you should know what the people speak.

Then I just want to continue with just a few more comments. My name is Terri Kekoolani. I'm a member of Ohana Koa, a Nuclear Free and Independent

Pacific. So on behalf of Ohana Koa I would like to say that we are absolutely against Star Wars, and that means that we would like to see the ending of all testing, development, and deployment of a Ballistic Missile Defense System.

Deployment of the Star Wars program threatens a new nuclear arms race, puts the global environment at risk, and undermines the security of the United States as well, and undermines the security of all people.

Also, Star Wars fuels the nuclear arms race. Deployment will increase the likelihood of a nuclear catastrophe. BMDS greatly increases tensions between the world's nuclear powers.

On June 13th, 2002, George W. Bush unilaterally and without a vote of Congress withdrew the United States from the Anti-Ballistic Missile Treaty, once a cornerstone of arms control. We denounced that unilateral action.

Also, Ohana Koa believes that Star Wars will have a significant adverse impact on native Hawaiians, our Marshall Island brothers and sisters, the Enewetaks, and other indigenous peoples; and that the Programmatic Environmental Impact Statement fails to consider these impacts.

Hawaiian burials and sacred sites are desecrated by the missile launches and Star Wars facilities, while cultural practices and subsistence

access rights are denied due to base security measures.

That is already taking place right now on Kauai. You folks have missile launching pads over there on top of an ancient burial ground. It's called Nohili. It is a crime. It's a crime.

And also there are now people being denied access to beach fronts that have traditionally always been accessible by our people.

So, anyway, on behalf of Ohana Koa, a Nuclear Free and Independent Pacific, we are totally against the Star Wars and want to make that very clear. Mahalo.

IKAIKA HUSSEY: Aloha kakou.

(Speaking in Hawaiian.)

In addition to my own opposition to the proposed ballistic defense system, I come here with words from people who were not offered the opportunity to testify this evening because there was no hearing on the island where they reside and where the impacts will take place.

I'd like to begin with offering the testimony of Mr. Jumble (phonetic) Kalaniole Fu who is a fisherman, commercial fisherman, in a family-owned business on the island of Kauai. He experiences on a regular basis the militarization of his island. He witnesses the missiles leaving Pole Hale. He witnesses the missiles flying up out of the ocean.

He is told that he can't fish in certain areas because of military work that's being done.

He's also very concerned because he's seen it for so long. He talks about 18 years of the people of Kauai constantly being told and being exposed to the Star Wars program to the point where they have become desensitized to it.

He's concerned about the effects that it has on his family. He's spoken to me about the fact that there is no research being conducted to ascertain health effects on the people of Kauai, about the propellants and all those things.

He is also very concerned simply because

of the very dangerous things that we're talking about here. We're talking about missiles. A missile has no function but to be a weapon, unless you put a person into it and they're going to explore outer space. Even in that case there's a probability that there's imperial notions at hand. But what we're talking about here are very dangerous things, and he is concerned about the possible dangers that might come upon him and his family and his people on Kauai.

He has seen missiles that misfired or missed their target and destroyed or -- apparently a missile hit another boat, another American vessel. And he doesn't want to see that happen either to the American military or to his own family. So that was his concern.

I also would like to relate the testimony of Mr. Wilfred who e-mailed me from Canada, and obviously there's no hearing in Canada, but he is very concerned because he knows that the proposed American military expansion, the full-spectrum dominance that we're talking about here, he is concerned about the effects that will have on him and his people in Canada.

He is concerned that it will spark a new arms race. He also mentioned to me that 70 percent of the people in Canada, of people polled in Canada, opposed the Ballistic Missile Defense System, so if that's an indication.

Since 1893, and actually before then, America and the greed of America and also the greed of other European countries, we've experienced that greed through military incursion consistently. American businessmen, European businessmen who wanted to set up shop in Hawaii and sell sandalwood and do whaling, and sell sugar and pineapples, the way that they were able to fulfill their avarice was by calling on the military of their countries to come and support them in their desire for Hawaiian land.

All the way through 1848 to the Mahele and then past the Mahele to 1893 we've had constant military invasions from the outside, people wanting our land for their purposes.

Since 1893 American military has only procreated in Hawaii. It's ironic, I know. And the guns that were pointed at the palace have multiplied, and now we're talking about missiles. And I can't bear the thought of my family and my family's land being part of anyone's desire for empire.

I have no desire for empire personally. I have no desire for dominating anyone. So I can't even fathom the idea of full-spectrum dominance. It seems absolutely inhumane, and I don't think that it is something that you folks or the people of America, people of the United States of America have innate to them. I don't believe that there's something that's genetic about Americans that says that they will try to promulgate empire. So I can only hope for the

emergence of humanity in the United States, and the toppling of a regime that will only promote dominance of other peoples.

(Applause.)

Finally, I would like also to present the testimony of 1,330 people who signed petitions opposing the expansion of military in Hawaii. And these people need to be included in the process. They need to be notified of the Record of Decision. Thank you.

DC_PHO0059
DR. FRED DODGE: Aloha kakou.

AUDIENCE: Aloha.

DR. FRED DODGE: My name is Fred Dodge and I'm a physician, a family practitioner. I'm happy to see two other family practitioners testifying today. We take seriously our role in trying to use preventive medicine in treating communities. I'm also a member of PSR, Physicians for Social Responsibility, and IPPNW stands for International Physicians for the Prevention of Nuclear War, and I also am a member of other organizations. I'm not here representing any of them officially. I speak for myself.

I want to add my voice to those who said that the process is flawed. You really need to hold hearings on Kauai, other places also, but especially Kauai where the Pacific Missile Range Facility is located, who are really greatly impacted by this. And I, too, have friends on Kauai who didn't know about it and want the opportunity to testify.

The Ballistic Missile Defense System, let's just call it Star Wars, everybody seems to know it by Star Wars, is really a part of our warfare state. A lot of people criticize the welfare state mentality, but we really have more of a warfare state mentality now more than ever.

(Applause.)

I think to those who have examined this whole system, it really has -- I mean, it's put

forth as a defensive system, but it really has a great deal of offensive capabilities, and is certainly seen that way by other nuclear powers, especially Russia and China.

I believe it to be dangerous to humans and other living things, and, therefore, I'm certainly against it.

I also question the conclusions of the PEIS in that alternatives that have been mentioned in the past aren't included. I won't go into that except I support those. The lack of detail on cumulative effects is a major defect. And I think the lack of environmental and racial justice needs to be addressed more fully certainly.

And after saying all this, believing it, I agree with Ron Fujiyoshi that it's shibai, this whole thing is something you just sort of go through, because it's going to get approved. But yet we must speak out.

Ghandi has said you have to speak truth to power, and certainly you guys have the power or you represent the government with the power, but we must speak out.

It seems to me that instead of threats from missiles, there's a lot more threats from the suitcase A bombs the U.S. had and then Russia developed the backpack. These are portable A bombs. The horrific thing about it is that the sources that I have read and listened to and so on say that a lot of

DC_PHO0059

these are not accounted for in Russia during the changeover, they're missing. Where are they? I mean, they're the things that can be brought into the U.S.

I don't know how many people are aware of the fact that about a month after 9/11 the U.S. received reports that one of these portable A bombs was somewhere in New York City.

Fortunately it turned out that this was not an accurate report, like many of our intelligence, it was not correct, but it's interesting to note that Mayor Guilliano was not notified of this at the time and was extremely angry when he found out that this had happened. And apparently there was no way, if that were to happen, to find it. That's a real threat, much more so.

The other thing that I want to mention is that all the information that I've read, mostly from independent scientists, says that the Star Wars project is very likely to fail. Originally the PSR, the Physicians for Social Responsibility, had taken up on that there was -- originally they said there would be six percent chance that a missile could get through, especially the multiple warhead type, and so they gave every member of Congress an umbrella with holes in the umbrella amounting to 6 percent of the umbrella surface. It won't keep you dry.

It's also extremely wasteful, and I think that's been addressed here today. It's bound to

DC_PHO0059

escalate the arms race.

I had a letter from the late Patsy Mink, representative from Hawaii, and I'll quote what she told me at the time. This is already three years ago. But she said: The National Missile Defense System has the potential to destabilize our relationship with other nuclear powers and will violate the Anti-Ballistic Missile Treaty, which was then in effect. And, as people have stated, our present president has withdrawn us. And certainly we question whether that withdrawal by the president, without congressional support, is legal.

She goes on to say: We should not deploy a system if we don't know whether it will work, which violates our treaty obligations and escalates deployment of nuclear weapons by potential adversaries. In other words, they see it as offense and they're going to be building up. And other people have stated the same thing.

So where are we at? In my opinion, we don't need it. The world certainly doesn't need it. The project should be abandoned. We could save billions. We could even use it for some human needs, such as 45 million people who don't have health insurance in the United States, for instance. This is where I come from.

I also was going to quote President Eisenhower, but that's been so eloquently quoted earlier.

DC_PHO0059

I'll just say that if there's any way possible to do some of those other alternatives, at least put this on hold, if not scrap it, I think that would be the way to go. Thank you very much.

(Applause.)

DC_PHW0001

BALLISTIC MISSILE DEFENSE SYSTEM
DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT

COMMENTS SUBMITTED ON BEHALF OF THE LAWYERS ALLIANCE FOR WORLD SECURITY, OCTOBER 14, 2004

One October 13, 2003 the Lawyers Alliance for World Security (LAWS) and the Physiciains for Social Responsibility (PSR) filed comments on the draft Environmental Assessment and Finding of No Significant Impact (FONSI) for the Ground-Based Midcourse Defense (GMD) Initial Defensive Operations Capability (IDOC) at Vandenberg Air Force Base. The thrust of the LAWS/PSR comments was that the Vandenberg EA did not satisfy the requirements of NEPA on several grounds, hence the limited conclusions drawn in the EA were arbitrary. In an October 24, 2003 letter responding to the LAWS/PSR comments, Mr. Jerry Hubbard, of the MDA Ground-Based Midcourse Defense Joint Program Office in Huntsville, AL stated (1) that many of the issues raised by LAWS/PSR would be analyzed in the PEIS; (2) MDA received unanimous concurrence and approvals from the pertinent regulatory agencies, and (3) "this project is not controversial." The basis for the latter statement was that MDA received only one other comment critical of the Vandenberg EA.

Mr. Hubbard's letter went on to state that – "The VAFB IDOC is a vital national project that will enable the United States to protect its citizens from potential adversaries. Although I cannot elaborate fully regarding these threats and the IDOC capability dur to the highly classified nature of the information, the VAFB IDOC will provide a critical defensive capability for the country that does not currently exist. Its timely completion fulfills President Bush's mandate to achieve an initial defensive capability by September 30, 2004 to provide a vital protection for the nation."

A. The NEPA Standard

In considering whether an agency's action is arbitrary and capricious, a reviewing court must consider whether the agency has taken the requisite "hard look" at the environmental consequences of the proposed action, carefully reviewing the record to ascertain whether the agency decision is founded on a reasoned evaluation of all the relevant factors. The Ninth Circuit in Greenpeace Action v. Franklin, 14 F.3d 1324 (9th Cir. 1982) pointed out that when determining whether a proposal will "significantly" effect the human environment, the agency must consider both the context (e.g. society as a whole, national, the affected region, etc.) and intensity (i.e., the severity of the impact). In evaluating intensity, the Court went on, consideration must be given to the degree to which the effects on the quality of the human environment are likely to be highly controversial; the degree to which the possible effects on the human environment are highly uncertain or involve unique or unknown risks, and whether the action is related to other actions with cumulatively

significant impacts. Significance cannot be avoided by terming an action temporary, or by breaking it down into small component parts.

Here, MDA has ignored the highly controversial nature of the missile defense program; has, over the years, issued a series of separate environmental analyses on smaller parts of the entire system, so as to avoid the cumulative impact test, and the nature of the proposed layered integrated BMDS program described in this PEIS is so substantially different from earlier iterations that any reliance on many of those earlier environmental analyses is misplaced. They simply will not pass muster. And, as the Ninth Circuit instructed another agency in a case involving a controversial proposal, "... the term 'controversial' refers to cases where a substantial dispute exists as to (the) size,nature, or effect of the major federal action rather than to the existence of opposition to a use." Foundation for North American Wild Sheep v. United States Department of Agriculture, 681 F.2d 1172 (9th Cir. 1982).

The assertion that the missile defense system described in the PEIS will defend the United States now, or by year-end 2004, or really anytime soon, is patently absurd. The system being deployed has no demonstrated capability against a real attack and is missing most of itsmajor elements, including(1) the X-Band radar; (2) the satellite constellations SBIRS-High and SBIRS-Low (the latter now called STSS), and (3) adequate discrimination capability by its exo-atmospheric kill vehicle interceptor, the EKV, which is also missing. The inescapable conclusion is that the Administration is deploying a system that doesn't work and hasn't been adequately tested.

As envisaged by the Administration, the system is to eventually include two satellites (one in high orbit, one in low) to assist in the early detection of missile launches, track missiles and help guide interceptors to their targets. Both satellites have fallen years behind schedule, so until the new radar arrives, the interceptors will have to rely in large part on radar systems that were developed in the 1960s and 1970s. The most important system, in the Aleutians,hasnot been tested for its new role, and, because of the way it is positioned, it would not be able to detect a North Korean launch aimed at Hawaii. Ten interceptors were scheduled to be in place, but currently there are only five or six, and no one knows whether they can hit anything, because they have not yet been tested against targets.

Yet another controversial aspect of the program is its budget. The missile defense budget has doubled in the past four years, and the appropriations for next year is more than ten billion dollars -- about the same as the Army's entire R & D budget, twice the budget of the Bureau of Customs and Border Protection in the Department of Homeland Security, and nearly twice the department's allocation for the Coast Guard. The MDA estimates that the program will cost fifty-three billion dollars through 2009, but it has grossly underestimated costs in the past.

The PEIS at 2-68 states that the alternative of canceling the development of all ballistic missile defense capability development and testing does not meet the need for the proposed action; does not meet the direction of the President and the U.S. Congress, and therefore "will not be analyzed further." One alternative not even mentioned in the PEIS would be to cut the spending in half, to allow the testing of a system that would eventually work against potential adversaries such as North Korea or Iran. Another would be to look at the realistic likelihood that if the US is ever confronted by a nation such as North Korea or Iran with a tested ICBM,

the option of military necessity would be to destroy such an enemy ICBM on its launchpad with precision-guided missiles if an attack seemed imminent. Yet another reason the discarded cancellation option has merit, at least for further analysis, is the statement submitted to the President by forty-nine retired generals and admirals who asked the President to put off the deployment and to transfer the funds to the securing of nuclear facilities and the protection of American ports and borders against the far more immediate dangers of Al Qaeda, rather than pursue a system that may never work against a system that doesn't now exist.

As the former Pentagon weapons evaluator, Philip Coyle, was quoted in the Washington Post on September 29, 2004 lead article on the missile defense program, the idea of deploying while testing – the Administration's current plan – is like building a picket fence, one picket at a time, over several years. As Mr. Coyle pointed out, until the whole thing is complete, such a fence is not much use.

B. The MDA Has Failed to Meet the NEPA Requirement for Considering a Range of Alternatives

The PEIS is defective to the extent that it fails to meet the CEQ guidance on the range of alternatives agencies must consider. Here, the MDA has failed to propose a real no action alternative, and the so-called no action alternative set out at PEIS 2-67 is not a true no action alternative because under it all the individual components of the system would continue to be tested to determine the adequacy of their stand-alone capabilities. Such an alternative could easily have been Alternative 3, but the MDA should also have clearly set out a real no action alternative so that the public could comment on it, instead of being caught in the Catch-22 this PEIS poses. It is difficult not to conclude that the agency's choice of alternatives was dictated by the end result it desired. While there may be portions of the CEQ guidance where reasonable people may differ, surely this is not one of them. And LAWS submits that a reviewing court would find the range of alternatives set out in the PEIS inadequate, in view of all the circumstances.

C. National Security.

The U.S. Supreme Court in Weinberger v. Catholic Action of Hawaii, 454 U.S 139 (1981) held that a NEPA impact statement was not required on the proposed use of facilities to store nuclear weapons. Later cases, however, have elaborated on the restrictions adopted by the Court in Weinberger, and in 1988 the Ninth Circuit noted that NEPA does not have a national defense exception, and that Catholic Action had implicitly rejected this defense. No Gwen Alliance, Inc. v Aldridge, 855 F. 2d 1380 (9th Cir. 1988) Romer v Carlucci, 847 F.2d 445 (8th Cir. 1988) held that federal defense legislation determined the scope of environmental analaysis under NEPA on the proposed deployment of MX missiles to missile silos, and that review of the impact statement on the deployment for compliance with NEPA was justiciable. In other words, using the current vernacular, relying on national security as a shield to preclude an adequate NEPA analysis is not a "slam dunk"defense.

D. Previous Litigation.

On August 28, 2001, the Natural Resources Defense Council, PSR and several other plaintiffs filed a complaint under NEPA against the Secretary of Defense, the Director of the BMDO, and the U.S. Department of Defense for failing to prepare adequate tiered environmental impact statements in view of the massive changes in the program announced by General Kadish in July 2001. The August 2001 Record of Decision, 66 Fed. Reg. 42848, that purportedly implements the NMD Deployment EIS affirms these fundamental changes: "Since the NMD EIS was completed, the Ballistic Missile Defense architecture has evolved into a multi-layered approach that does not distinguish between national and theater threats."

As the plaintiffs noted at p. 19 of the complaint, " There are myriad environmental impacts associated with the activities associated with the new BMD program. These include major impacts from construction of new facilities and testing programs at site in Alaska, Colorado, Hawaii, the Marshall Islands, California, and other possible locations; disruption of unique and pristine ecosystems from activities such as laying communications cable and test launches, which in some cases, like the Kodiak Launch Facility, are located in largely untouched environment that harbors endangered or threatened species; significant deposition of space debris from numerous planned interception tests in low earth orbit, where it can collide with and cripple existing and future satellites; and depositions in the atmosphere of large quantities of ozone-depleting chemicals from the numerous rocket launches required to test and deploy elements of the proposed system."

The lawsuit was subsequently settled, but the fact that it had been filed and that it mentioned space debris focused on a very significant aspect of the proposed program.

E. Space Debris.

LAWS endorses and incorporates by reference the excellent discussion of space debris in the statement prepared by Theresa Hitchins, CDI Vice President, entitled "Missile Defense Agency Fails to Adequately Address Dangers of Orbital Debris to Spacecraft, People,and Objects in Space, the Air, and on the Ground." As Ms.Hitchins makes clear, the PEIS fails to adequately analyze and discuss the possible dangers of debris in space. If the missile defense program has an Achilles heel, this is it. It is inexcusable for the MDA not to have undertaken or provided adequate scientific review of the physics involved in debris creation and re-entry, as well as of the multiple scenarios for missile defense intercepts. The dangers to people, and to objects in the air and on the ground are real, yet the PEIS blithely ignores such dangers. Depending upon the missile trajectory, debris could also be a threat to Canadian citizens, aircraft and ground facilities. As Ms. Hitchens notes, all trajectories to the continental US from North Korea pass over both Canada and Russia, so that both nations are potentially at risk from boost-phase shortfall.

As LAWS and PSR pointed out in their Vandenberg EA comments, "The issues are too important, and the priority accorded this program would suggest to a reviewing court that rather than risk extended delays inherent in legal challenges to the sufficiency of this (PEIS), the MDA would be well advised to take the time and make the effort to prepare a comprehensive (PEIS) that fully meets all the legal requirements of NEPA." That is still good advice. While the PEIS is an improvement in some respects, it remains fatally flawed. LAWS and PSR and others will spell out these fatal flaws in the written comments that are due November 17,2004.

Written comment on draft Ballistic Missile Defense System (BMDS) Programmatic Environmental Impact Statement (PEIS)

By Victoria Samson
Research Analyst, Center for Defense Information

October 14, 2004

The draft Ballistic Missile Defense System (BMDS) Programmatic Environmental Impact Statement (PEIS), dated Sept. 1, 2004, is supposed to give an objective and thorough assessment of the effects various missile defense architectures would have on the environment. However, it obviously been shaped to give credibility to the Bush administration's continued assertions that the only way the United States can be protected from an ICBM attack is with a heavily tiered system. The draft PEIS dismisses any real concerns about harmful negative consequences from developing such a system and, in doing so, invalidates itself and its conclusions.

To begin with, the so-called "No-action alternative" examined in this document is misleadingly named. It does not detail a scenario where no action is taken. Rather, it describes a system where "the MDA [Missile Defense Agency] would continue existing development and testing of discrete systems as stand-alone missile defense capabilities. Individual systems would continue to be tested but would not be subjected to system integration tests." (p. ES-8) This is hardly no action and allows for an indeterminate amount of missile defense development, since "There are currently no final or fixed architectures and no set operational requirements for the proposed BMDS." (p. 1-9) The way this draft PEIS is structured, even if MDA was limited to the No-action alternative, it would not find its actions very much constrained.

Alternative 2, which includes the usage of space-based interceptors (SBIs), is questionable for many reasons. It looks at the effect of using space-based interceptors in lieu of terrestrial-based ones; however, the BMDS that is repeatedly envisioned by MDA and Pentagon officials is one where targets would be engaged at all stages in their flight, from all types of launch platforms. To look only at the usage of an SBI is to willfully ignore the concept of operations that has been used to justify this massive defense system. The American Physical Society, in its boost-phase intercept study released in July 2003, estimated that a constellation of at least 1000 SBIs would be required to provide a minimal defense against liquid-fuelled ICBMs. Granted, testing would be of a much lesser nature than a complete constellation, but at some point presumably the system would be tested at some fraction of its full strength. This draft PEIS does not take into consideration that possibility.

This draft PEIS also does not look at what would be required to develop a space-based test bed, dismissing the concept as being "too speculative to be analyzed in this PEIS." (p. 2-29) It does not say when such a concept would be analyzed. Finally, this document admits, "If Alternative 2 were selected, additional environmental analysis could be needed as the technologies intended to be used became more defined and robust." (p. 4-

DC_PHW0002

116) But again, that is what this document is supposed to do: examine the environmental effects of the proposed action. By sweeping it under the nebulous responsibility of future studies, it relieves the MDA of liability of negative consequences stemming from SBIs.

Nowhere is this dismissive attitud ed more clearly than in how the draft PEIS treats debris, orbital and otherwise. Orbital debris is listed as a resource consideration "because of the likelihood of orbital debris occurring from various launch and testing activities and its potential for impact to health and safety and the environment." (p. ES-12) Yet in every case that orbital debris is detailed as resulting from the proposed actions, it is written off as a non-threat to space assets or the terrestrial environment. It is claimed that the orbital debris from booster failure, for example, would be on-orbit for too little time to create damage, and that it would burn up upon re-entry, but even if it didn't, the likelihood of damage is small. (p. ES-21) This same justification is repeated ad nauseum throughout the document. The draft PEIS does admit that the International Space Station (ISS) may be affected by orbital debris, but again downgrades the threat, saying that the ISS could merely do collision avoidance to ensure its safety. (p. ES-39) This no doubt comes as surprise to our partners in the ISS who were unaware that we were planning on weapons systems that very well could destroy our joint effort unless valuable fuel was used to effect a collision avoidance strategy.

This dismissal of the threat of orbital debris to space assets contradicts statements made elsewhere in the draft PEIS. The document discloses that "little advance warning could be given to clear air space" if an SBI had an uncontrolled reentry. (p. 4-121) And, with a nod to the unpredictable, the document says, "Objects reentering may skip off the Earth's atmosphere, similar to a stone skipping across a pond, causing them to impact much farther away than originally predicted." (p. 4-122) Despite this, the document still clings stubbornly to the conclusion that orbital debris would have no significant impact.

The draft PEIS fails to fully address the effects of other types of debris - rocket fragments, fuel, and so forth. Again, it barely scratches the surface of potential harmful consequences that could plausibly result from the alternatives listed, and again, it immediately dismisses the few consequences that are divulged. Debris that could fall into the ocean "would become diluted and would cease to be of concern." (p. 4-51) Debris that survived reentry is not to be worried about, as it would fall into a pre-established footprint, and even if it didn't, "Debris is more likely to terminate in water than on land because water covers 75 percent of the Earth's surface." (p. 4-119) Debris from spills or intercepts in the air is assumed to dissipate before it hit the ground. (p. 4-24)

Yet this is making a real leap of faith in how these actions wou ent, and doing so in a manner that precludes any real assessment of ences could occur. The treatment of the Airborne Laser (ABL) is indicative of this attitude. The draft PEIS says that should the ABL be not able to land at "an appropriate location," its fuel and laser chemicals may have to be jettisoned, but this would be at a minimum altitude of 15,000 feet and thus "would be diluted in the atmosphere." (p. 4-24) And if there was an accidental fire on the ABL, "the liquid and solid laser chemicals would be

DC_PHW0002

consumed or contained." (p. 4-34) These laser chemicals include hydrogen peroxide, ammonia, chlorine, helium, and iodine, according to the document. (p. 4-24) No explanation is given as to what would happen should the ABL jettison its chemicals at a lower altitude than 15,000 feet, nor how exactly the fire would contain all chemicals. The draft PEIS makes these reassuring statements with no solid evidence to back them up.

Another issue that is raised and not explored fully is the testing and deployment of missile defense systems abroad, or OCONUS as it is referred to here. The document asserts, "MDA may also develop test beds in other areas such as the Atlantic Ocean, Gulf of Mexico, or outside the continental U.S. to support testing of BMDS components in those areas." (p. 2-28) But it does not say how this would occur, only that "Because NEPA and other environmental laws generally do not apply to OCONUS activities, various EOs and other DoD directives and instructions have been implemented." (p. 4-111) However, nothing specific has been given on how these laws were implemented; rather, the draft PEIS directs the reader to Appendix G, which is a long listing of international treaties and does not explicitly state how the missile defense systems fit into these commitments. Given how unpopular missile defense is amongst the Canadian, British, and Greenlandic publics – the three countries that are the nearest to being incorporated into the BMDS – this should be explained further.

Finally, the alternatives considered but not carried forward are deliberately chosen to showcase the BMDS systems that the Bush administration has been pushing for in the best light possible. The first one is to cancel development of BMD capabilities, which is explained as being an alternative that "would rely upon diplomatic and military measures to deter missile threats against the U.S." (p. 2-68) This is exactly what has kept the United States safe from attack to date, and yet it is summarily dismissed out of hand. The other alternative is to focus on a single- or two-platform BMDS. But, per MDA threat assessments that are not given but merely referred to, it has decided that "an effective missile defense should include components based on at least the land, sea, and air," so a more limited missile defense system simply would not do. (p. 2-68)

This draft PEIS does not fully examine the actual consequences that could very well result from developing and testing a tiered missile defense system. By deliberately rejecting any and all negative effects, it goes against what is legally required of the NEPA process.

Ballistic Missile Defense System
Draft Programmatic Environmental Impact Statement

Missile Defense Agency Fails to Adequately Address Dangers of Orbital Debris to Objects and People in Space, in the Air and on the Ground

Comments Submitted to the Department of Defense Missile Defense Agency

Theresa Hitchens
Vice President and Director of Space Security
Center for Defense Information

Introduction

On Sept. 1, 2004, the Pentagon's Missile Defense Agency (MDA) released its legally required Draft Programmatic Environmental Impact Statement (PEIS) on the testing and employment of its future ballistic missile defense system. The PEIS, however, dramatically fails to address the potential dangers (both to space-based objects and those on the Earth) from space debris that MDA admits will be created by testing or use of ballistic missile interceptors. The PEIS states (p. ES-33): "Proposed BMDS space-based sensor activities would be expected to produce small quantities of debris, primarily explosive bolts and small pieces of hardware. It may be possible for debris from an exoatmospheric intercept to become orbital debris. However, because the majority of the BMDS activities would occur in Low Earth Orbit where debris would gradually drop into successively lower orbits and eventually reenter the atmosphere, the debris would not be a permanent hazard to orbiting spacecraft. As BMDS testing becomes more realistic, there is a potential for an increased amount of debris reaching and remaining on orbit. A large portion of this debris would likely not remain on orbit for more than one revolution, and eventually all of the debris would be expected to de-orbit."

While these statements are perhaps true, they also serve to downplay the possible dangers of debris. The overall assumption in the PEIS that there is a low-level of risk is not supportable, due to the failure of MDA to undertake or provide adequate scientific review of the physics involved in debris creation and reentry, as well as of the multiple scenarios for missile defense intercepts. The following is an overview of the major inadequacies in the PEIS treatment of issues related to orbital debris.

The Dangers to Spacecraft from Orbital Debris

The PEIS fails to adequately address space as an environment that will be impacted by interceptor testing, deployment and usage.

It is a universally accepted fact that space is an environment that belongs to all humankind and thus must be protected. For example, harm to the space environment prohibited by both the 1967 Treaty on Principles Governing the Activities of States in the Exploration and Use of Outer Space, including the Moon and Other Celestial Bodies (known as the Outer Space Treaty) and the 1977 Convention on the Prohibition of Military or Any Other Hostile Use of Environmental Modification Techniques (know as the Environmental Modification Convention). It is also universally recognized that the space environment is in danger, becoming ever more polluted by orbiting junk left over from human activities in space. Space debris is the inevitable consequence of the global uses of space every single space launch will create some amount and form of debris, just as every kind of public transport on Earth creates some amount and form of pollution. Examples of space debris include: satellites that no longer function; spent and jettisoned rocket bodies; lens caps, bolts, and "exhaust products" from solid rocket motors and small particles such as paint flakes and bits of insulation from day-to-day erosion of orbital objects.

Already, there are ongoing efforts at the UN level to develop universally accepted practices to mitigate the creation of new space debris by space-faring powers; NASA is a key leader in this effort. "It's a classic environmental problem," according to Nicholas L. Johnson, chief scientist and program manager at the Orbital Debris Program Office at NASA's Johnson Space Center in Houston. "If you don't do anything about this for the next 10 or 20 years, then it's too late."

Space debris is dangerous because of its potential to collide with and damage satellites and/or spacecraft. Even tiny pieces of debris can cause destruction. Debris is so dangerous because objects in orbit move at extremely high speeds (about 10 kilometers per second in Low Earth Orbit) and so relative velocities and the energy generated at impact can be very large. The damage that would be caused by a collision in space depends on a number of factors, such as the size of the debris, the size and design of the spacecraft hit, and at what angle the two objects collide. Indeed, the PEIS itself admits that space debris created by missile defense activities (particularly multiple interceptor launches) could present a threat to the International Space Station and other objects in Low Earth Orbit (LEO).

The PEIS severely understates the potential threats to satellites and spacecraft from orbital debris caused by ground-based midcourse interceptor tests, deployment and usage, due to a failure by MDA to conduct adequate scientific review of the likely scenarios for interceptor impact and debris creation.

Ground-based interceptors will create debris in LEO if they impact their targets (Intercontinental Ballistic Missiles [ICBMs] fired at the United States) in the so-called

mid-course phase, when they are outside the Earth's atmosphere. In this phase, the ICBM will be either rising into LEO, at the peak of its trajectory, or starting to descend back through space into the atmosphere. The PEIS states, "The amount of orbital debris could increase from …Ground-based Midcourse Defense … . Such increases in orbital debris would be temporary, as studies indicate that objects in orbit between 200 and 399 kilometers (123 to 248 miles) reenter the atmosphere within a few months."

This statement, however, is somewhat misleading. Up to now, MDA has been configuring ground-based, mid-course intercept tests so as to avoid debris creation, conducting tests at low altitudes and slow speeds, with both interceptor and target on a downward trajectory, so debris created will rapidly reenter the atmosphere. In the last successful test in October 2002, the interceptor hit the target at an altitude in excess of 210 kilometers (140 miles) above the Earth, at a speed of about half of what would be required in a real-life scenario. Realistic testing and employment of a ground-based mid-course system would require intercepts at higher altitudes orbit of around 300+ kilometers and extremely high speeds, and would more likely take place with both the interceptor and the target flying in an upward trajectory -- facts of physics that would lead to the creation of more debris and likely result in debris being flung into a higher orbital plane than the altitude of the intercept itself. If the debris ends up orbiting at higher than 399 kilometers, it could remain in space for years. There is no evidence that the PEIS takes into account this latter possibility.

Even if the debris remains in space only for a "few months" it would still pose a potential threat to space assets in its orbital pathway, including perhaps, as the PEIS itself admits, the International Space Station (ISS). While, as the PEIS notes, the ISS can be (and has been in the past) moved to avoid potential collision with space debris, this is not a simple task and takes time. Indeed, the PEIS couches its language on threats to the ISS by saying only that it "may be possible" for the ISS to perform collision avoidance to get out the way of any "large debris" created. Further, many other satellites in LEO lack the ability to maneuver at all to avoid debris – a fact that the PEIS fails to mention.

Finally, the PEIS contradicts itself somewhat on the issue of debris risk by stating (on p. 4-132) that since the "debris created is expected to be small" and collision avoidance strategies could be used, there are "no significant impacts expected to the ISS." While it is debatable whether the debris would indeed be "small" – as the PEIS provides no actual modeling to predict the size of debris created by a ground-based midcourse intercept the fact is that small debris could actually be *more* dangerous to the ISS and other spacecraft in LEO. That is because current debris tracking systems cannot track debris smaller than 10 centimeters in diameter (about the size of a softball) adequately enough to allow planning of collision avoidance maneuvers. Debris between 10 cm and 1 cm in diameter (a bit larger than a marble) will penetrate and damage most spacecraft (as the PEIS admits on p. 4-131) and could possible destroy space assets depending on where debris strikes the spacecraft. It also should be noted that the orbital plane between 300 and 400 kilometers is already one of the bands of space most polluted with this size of debris.

The PEIS completely fails to support its claim that there would be no significant impact to spacecraft from the use of Space-Based Interceptors (SBIs) for either boost-phase intercept (as an ICBM is rising into the upper atmosphere) or midcourse intercept, due to the inability of the MDA to provide data required for necessary scientific review.

Given the inadequate articulation by MDA of the SBI concept and the lack of sufficient scientific coverage of space debris in this PEIS, it is impossible for the PEIS to make *any* claims about potential debris production from SBI tests, deployment or usage other than that the creation of debris is a certitude. The PEIS states (p. 4-118), "Using interceptors from a space-based platform would create orbital debris, from successfully intercepting a threat missile and causing it to break up or from the break up of any unsuccessful interceptor or space platform." It further notes (p. 4-118) that SBIs would travel through space after launch, and thus potentially endanger other satellites it their path. It does not, however, mention the fact that launching an SBI constellation into either LEO or GEO would also have debris impacts that might be significant.

The dangers of the debris created, however, can not be scientifically analyzed because the configuration of the SBIs themselves (i.e., their size, mass and speed) has yet to be revealed by MDA; neither has the architecture for their deployment (how many SBIs on orbit and at what altitude) or usage (how many SBIs would be fired at an incoming target) been publicly determined. As noted above, the potential for debris creation depends on a number of factors including the mass of the two objects, the speed of the impact, the altitude of the impact, and the angle of impact. With none of the specific parameters identified for a SBI system by MDA (including in this PEIS), these factors are impossible to model.

Second, even if "best guesses" about a SBI configuration are used based on previously proposed and internal MDA designs, the PEIS fails to take into account the issues mentioned above regarding altitude, size and persistence of debris created by midcourse intercepts, and likely dangers to spacecraft from it.

Third, and perhaps the most egregious inadequacy in the PEIS review of the SBI option, proposals for a SBI network postulate between 500 and several thousand interceptors in LEO each of which would be filled with a large amount of highly-volatile rocket fuel. Thus, the SBIs themselves would be in potential danger of colliding with space debris already on orbit. Such collisions could result in the explosion of the SBI. In fact, current orbital debris mitigation regulations in the United States and elsewhere, as a first-order priority, require space operators to vent any excess fuel from booster rockets used in launching satellites in order to avoid on-orbit explosions, which are proven to create vast amounts of wide-spread debris. The SBIs would also be constantly bombarded by smaller debris that could comprise their integrity. The PEIS completely ignores the possibility of SBIs being damaged by debris. And while the PEIS suggests the possibility that some SBIs also might be based in GEO, there is no effort to address the even more serious threats this architecture would pose to spacecraft. An SBI traveling toward the Earth from GEO would have many more opportunities to collide with other spacecraft as it passed

through subsequently lower orbital altitudes. Also as GEO is already highly crowded with satellites (mostly for commercial communications and broadcast), the threat of debris creation by a network of new, explosive SBIs based in that orbital band could be high. Neither of these potential threats is modeled in the PEIS.

Indeed, the PEIS itself states (p. 4-116) that "additional environmental analysis could be needed as the technologies intended to be used became more defined and robust." Even more worrisome, an article in the Sept. 13 edition of *Space News* ("Space-Based Interceptor Could Pose Debris Threat") reveals that MDA has not even held detailed discussions about the potential for damaging debris from space-based interceptors with NASA's Orbital Debris Program Office.

The Dangers to People, and Objects in the Air and on the Ground

The PEIS makes blanket statements about the lack of danger to aircraft, terrestrial objects and people from space debris created by midcourse intercept activities reentering the atmosphere that cannot be supported in the absence of further scientific review.

Space debris can also be a danger to people and things on the ground, as some space junk will inevitably de-orbit, drop through the atmosphere and land. Although such landfalls are rare, they do happen when very large space objects de-orbit. For example, large pieces of Skylab fell over Western Australia in July 1979; in April 2000 pieces of a Delta 2 second stage rocket fell over Cape Town, South Africa. In the latter case, more than 700 pounds of debris hit the ground, including a nearly intact fuel tank. The Delta rocket had been used to lift a satellite to Geosynchronous Orbit (some 36,000 kilometers) in 1996. A nearly identical event happened in January 1997, when a Delta 2 second stage hit the ground in Georgetown, Texas. One of the pieces of debris from that landfall was a 264 kilogram (580 pound) stainless-steel fuel tank identical to the once recovered in South Africa. That tank came about 50 yards away from a house, and also nearly missed a highway.

The PEIS states on a number of occasions that any debris reentering the atmosphere from a midcourse intercept (by either ground-based or space-based interceptors) event would likely be "small" and thus "burn up" before impacting the ground. Considering that a Delta 2 second stage is a good bit smaller than either an ICBM or the current design of the ground-based midcourse interceptor, that statement is debatable. Nor is it supported by the PEIS itself, which simply does not provide the scientific analysis needed to determine the size of debris created by a midcourse intercept or the possibility of it making landfall intact.

For example, in the case of a booster malfunction or a miss by an interceptor successfully launched from the ground, large pieces of debris likely would fall back to Earth. There is little evidence given in the PEIS to back its contrary assertion that debris would be small and limited in its "footprint." Even in the case of a successful intercept, there is no data

DC_PHW0003

provided by the PEIS about the likely size and altitude of debris, data that is required to predict whether or not pieces would make landfall intact.

As the size, mass and speed of any SBI remains undetermined by MDA, it is impossible for the MDA at this time claim that there would be little risk of landfall by debris. However, the possibility of an SBI missing its target and reentering the atmosphere is worrisome, and should be further reviewed using reentry modeling based on several SBI configuration options – modeling that has not been provided by the PEIS.

The PEIS (p. 4-70) also states that "even if an object does survive reentry, only one third of the Earth's surface is land area, and only a small portion of this land area is densely populated. The chance of hitting a populated land area upon reentry would be small." While this is a statement of fact, it does not take into account the trajectory of likely missile tests or intercepts over the Earth. Where reentry might happen is dependent on from where the target missile is launched as well as from where the interceptor is launched, and at what point in their individual trajectories impact is made. The PEIS fails to provide specific data about likely intercept scenarios required to model possible reentry points. For example, there is some question about MDA's ability to do intercept tests from Ft. Greely, the first location for the new ground-based midcourse interceptors, because of concerns about endangering people and the environment. Finally, the PEIS itself admits (p. 4-122) that "Objects reentering may skip off the Earth's atmosphere, similar to a stone skipping across a pond, causing them to impact much farther away than originally predicted."

The PEIS fails to adequately review the likelihood of risks to both aircraft and objects and people on the ground from debris created by space-based boost-phase intercept activities.

In the case of a SBI launch designed to hit an ICBM in its boost phase, it is currently (as with a midcourse design) impossible to predict with reliability the potential for debris to make landfall intact due to the lack of data about the configuration of SBIs. That said, however, a miss likely would result in major ground impact. That is because by any design, an SBI *must* be able to survive reentry of the atmosphere so as to hit the target ICBM before it *exits* the atmosphere. This issue is not addressed by the PEIS at all – and represents a fact that seems to run directly counter to the PEIS's assertion (p. 4-121) that, "Upon reentry, the majority of the space-based interceptor and its platform would burn due to the intense friction and heat created during reentry through the Earth's atmosphere."

Finally, the PEIS admits that any accident (such as a communications failure caused by a defect or jamming) that caused an SBI to reenter the Earth's atmosphere in an uncontrolled manner could create a danger to aircraft in flight. It states (p. 4-121), "Given the difficulty in predicting that path of uncontrolled reentering space-based interceptors and their associated platforms, little advanced warning could be given to clear airspace." It then goes on to assert that most objects break up upon reentry and the impacts to airspace would not likely be significant – an assertion for which no scientific backup is

DC_PHW0003

provided, especially given the fact that SBIs designed for boost-phase intercept would by their nature be required to reenter at least the upper atmosphere intact. Further, even smaller pieces of white-hot debris could severely damage an aircraft in flight.

PERCHLORATE AND THE PROPOSED BALLISTIC MISSILE DEFENSE SYSTEM:
COMMENTS ON THE PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT

Lenny Siegel
October, 2004

Executive Summary

The Programmatic Environmental Impact Statement (PEIS) for the Ballistic Missile Defense System (BMDS) not only does an inadequate job of addressing the environmental impact of solid rocket propellant associated with this program, but it seems to ignore the purpose of the National Environmental Policy Act (NEPA). That is, rather than consider how to minimize negative environmental impacts in the design of a program, through "cradle to grave analysis," it uses the environmental document to justify decisions that have already been made.

Furthermore, the PEIS lacks a genuine "No Action Alternative," even though NEPA requires that such an alternative serve a baseline against which to compare the environmental impacts of the other alternatives. In particular, a No Action Alternative that posits little or no use of rocket propellant is essential if the program's proponents are to minimize releases of pollutants—particularly solid rocket propellant and its byproducts—into our nation's water supplies, air, or the upper atmosphere, either by selecting a program alternative or agreeing to binding mitigation measures.

Solid rocket propellant that contains ammonium perchlorate as an oxidizer is designed to generate large quantities of hydrogen chloride, which reacts with moisture in the atmosphere to create hydrochloric acid—that is, acid precipitation. The PEIS should consider how the missile defense program might develop and test alternate launch technologies that are not so environmentally destructive.

DC_PHW0004

When rockets are launched into the upper atmosphere, they directly deliver hydrogen chloride to the ozone layer, exposing human, other animals, and other biota to the harmful, persistent effects of ultraviolet-B radiation (UVB). Rocket launches are among the largest causes of ozone depletion, and the persistence of such substances from other sources is no excuse for additional pollution. The BMDS program should at the very least evaluate the mitigation of such seriously harmful environmental consequences through the development and deployment of alternative solid rocket propellants.

Perchlorate, primarily from the manufacturing, testing, aborted launches, maintenance, and decommissioning of solid rocket motors, is polluting the drinking water of more than twenty million people and may be endangering natural ecosystems from Cape Canaveral to the Marshall Islands. The PEIS understates the risks of exposure, and it fails to provide data on the quantities of solid rocket propellant likely to be produced, used, released, and disposed by the BMDS. The PEIS should consider the environmental consequences of various disposal strategies so the BMDS program can develop the technology or capacity to address its waste or consider the use of alternative launch technologies or strategies to minimize either the waste or the negative environmental impacts.

Conclusion

To ensure maximum environmental protection and reduce known, widespread human health risks from the use and disposal of solid rocket propellant, the Programmatic Environmental Impact Systems for the Ballistic Missile Defense System should compare the proposed alternatives against a genuine No Action Alternative. At a minimum it should::

1. **Provide more detailed estimates of perchlorate waste likely to be generated by system development, testing, deployment, maintenance, and decommissioning *and* acknowledge emerging regulatory standards for perchlorate exposure.**

2. **Consider in detail the management practices—launch protocols, treatment technologies, etc.—necessary to mitigate the significant environmental impacts, including increased depletion of the stratospheric ozone layer and the likely release of perchlorate into groundwater, surface water, and soil.**

3. **Evaluate alternative launch technologies not based upon ammonium perchlorate.**

Based upon such additional environment review, which I believe is mandated by any fair reading of the National Environmental Policy Act and its implementing regulations, Program Managers should use the information generated to help evaluate all alternatives and to mandate actions to minimize or mitigate the serious environmental consequences associated with such a large and continuing use of solid rocket propellant. Such steps are necessary to protect the American people, the ostensible purpose of the Ballistic Missile Defense System.

Introduction

I have been asked, by Physicians for Social Responsibility-Los Angeles, to review the draft Programmatic Environmental Impact Statement (PEIS) for the Ballistic Missile Defense System (BMDS), with a focus on the environmental impact of solid rocket propellant associated with this program. I find not only that the PEIS does an inadequate job of addressing these impacts, but like many other environmental reviews it seems to ignore the purpose of the National Environmental Policy Act (NEPA). That is, rather than consider how to minimize negative environmental impacts in the design of a program, through "cradle to grave analysis," it uses the environmental document to justify decisions that have already been made.

The PEIS lacks a genuine, "No Action Alternative," as required under NEPA. It rejects evaluation of the alternative, "Cancel Development of Ballistic Missile Defense Capabilities," because it "does not meet the purpose of or need for the proposed action ..." (page 2-68). This approach misunderstands how NEPA works. It is acceptable to evaluate and reject a No Action Alternative because it doesn't meet the purpose of a program, but the environmental impacts of that alternative must be considered as a baseline against which to compare the environmental impacts of the other alternatives.

In particular, a No Action Alternative that posits little or no use of rocket propellant is essential if the program's proponents are to minimize releases of pollutants into our nation's water supplies, air, or the upper atmosphere, either by selecting a program alternative or agreeing to binding mitigation measures.

The bulk of my analysis focuses on the manufacture, use, and disposal of solid rocket propellant containing ammonium perchlorate, because that is the propellant to be most widely used by the Ballistic Missile Defense program. However, liquid propellants, such as the hypergolic propellant containing hydrazine compounds and nitrogen tetroxide, are highly toxic, and the PEIS should consider how to minimize their environmental, health, and safety impacts as well.

At least by number, the 515 projected BMDS launches over the decade beginning this year dwarfs the 99 other projected government launches and the 77 estimated U.S. commercial launched anticipated over the same time period. The environmental review of such a large system, to be developed over a period of many years and potentially deployed for decades, provides an opportunity to reconsider the technologies that our country uses for launching rockets. The draft Programmatic Environmental Impact Statement ignores that opportunity.

Air Emissions

Solid rocket propellant that contains ammonium perchlorate as an oxidizer is designed to generate large quantities of hydrogen chloride. That is, hydrogen chloride is not generated as a product of incomplete combustion of when a system leaks. Rather, it is released as the normal combustion product of the reaction of aluminum and ammonium perchlorate. Then, hydrogen chloride reacts with moisture in the atmosphere to create hydrochloric acid—that is, acid precipitation. The PEIS briefly recognizes this:

> In biomes where rain is a frequent occurrence, launches with solid boosters have an increased likelihood of contributing to acid rain, thereby increasing the amount of HCl deposited in regional surface waters. In areas with low velocity of surface and groundwater movement and relatively shallow ground water table it is possible that deposition of acidic water may impact water resources. The potential for and extent of impact would need to be examined in site-specific environmental analysis. (page 4-60)

Waiting for site-specific analysis in the indefinite future condemns project sites to acid precipitation. There is no hint of how such an environmental impact might be mitigated. The proper analysis, at this stage, is to consider how the missile defense program might develop and test alternate launch technologies that are not so environmentally destructive. That is, the best solution is not likely be site-specific, so the PEIS itself should evaluate this impact.

The PEIS suggests that aluminum oxide, the other major combustion product of solid propellant, is non-toxic. (page 4-60) However, there is some evidence that aluminum in acid environments is toxic to fish.[1] The PEIS should review the literature and reconsider its conclusion based upon the weight of evidence.

Ozone Depletion

Furthermore, when rockets are launched into the upper atmosphere, they directly deliver hydrogen chloride to the ozone layer that protects the Earth against the harmful, persistent effects of ultraviolet-B radiation (UVB). The hydrogen chloride breaks down, releasing chloride ions that trigger catalytic reactions in which one chlorine atom can destroy over 100,000 ozone molecules. I call the delivery of chloride, in the form of rocket exhaust, to the upper atmosphere: "Free-basing the ozone layer."

Increased exposure to ultraviolet radiation causes universal damage to both human health and the natural environment. "... UVB causes nonmelanoma skin cancer and plays a major role in malignant melanoma development. In addition, UVB has been linked to cataracts.... Physiological and developmental processes of plants are affected by UVB radiation.... Scientists have demonstrated a direct reduction in phytoplankton production due to ozone depletion-related increases in UVB.... Solar UVB radiation has been found to cause damage to early developmental stages of fish, shrimp, crab, amphibians and other animals...."[2]

Once again, the PEIS acknowledges this environmental impact, but it plays it down: "The cumulative impact on stratospheric ozone depletion from launches would be far below and

[1] See, for example, Baker & Schofield, "Aluminum Toxicity to Fish in Acidic Waters," *Water, Air, and Soil Pollution*, 1987, cited in Heinz J. Mueller, Chief, Environmental Policy Section, Federal Activities Branch, U.S. EPA Region 4, "Environmental Assessment (EA) and Finding for No Significant Impact (FONSI) for the Proposed Titan IV Upgrade Program, Cape Canaveral Air Force Station (CCAFS) and Kennedy Space Center (KSC), FL," letter to Captain Anthony E. Fontana, III, Environmental Planning Division, Regional Civil Engineer, Eastern Region, Department of the Air Force, March 28, 1990.

[2] "The Effects of Ozone Depletion: The Connection Between Ozone Depletion and UVB Radiation," U.S. EPA, June 21, 2004. http://www.epa.gov/ozone/science/effects.html

indistinguishable from the effects caused by other natural and man-made causes." (page 4-114). I appreciate the data presented in Appendix I, but the conclusion reached by the authors is implausible.

The PEIS estimates that proposed BMDS launches from 2004 through 2014 would release approximately 1,350,000 kilograms (3,000,000 pounds) of chlorine, primarily in the form of hydrogen chloride, in the stratosphere. Annually, that would be 135,000 kilograms (300,000 pounds). In comparison, official U.S. EPA data estimates annual (2001) U.S. emissions of most destructive industrial ozone-depleting chemicals to total about 50,000,000 kilograms (110,000,000 pounds).[3] Compensating for the chlorine share of the industrial molecules, this means that the potential BMDS launch impact represents about .4% (.004) of the U.S. contribution to ozone depletion.

However, the industrial "emissions" are actually the residuals of production and use of chemical which have been phased out, under the Clean Air Act Amendments of 1990 and a series of international protocols. That is, these substances are already in the environment; nothing can be done to put them back in the bottle. Thus, each year stratospheric releases of rocket fuel exhaust become a larger fraction of the problem, as fewer industrial ozone-depleters are manufactured.

More important, the fractional contribution of rocket-launches to ozone depletion does not make it desirable. It is as large as all but the largest industrial releasers, before the phase-out took effect, and orders of magnitude larger than the releases from a home refrigerator or a car air conditioning system. Our environmental laws and policies do not excuse pollution simply because there are other, larger sources. That is, if I were a repairer of air conditioning systems, I could not—and should not—release chlorine-containing refrigerants into the atmosphere simply because a Titan or Delta launch vehicle emits much more chlorine.

For those unfamiliar with the working of our environmental laws, an analogy in criminal law might be instructive. We don't legalize shoplifting simply because some people conduct million-dollar armored car heists. We may tailor our response to the crime, but we don't say it's acceptable.

Similarly, with the release of ozone-depleting compounds to the atmosphere, we as a society might decide that we shouldn't abruptly end space launches that depend upon solid rocket propellant. Instead, we might set a goal for the deployment of alternatively fueled rockets. The PEIS considers no such goal, despite the urgent need to mitigate global ozone depletion.

The Defense Department, NASA, and others have conducted research on propellants designed to achieve the thrust of ammonium-perchlorate-based fuels without the environmental hazards, but these efforts are poorly funded, and there appears to be no urgency. The BMDS program should at the very least, in its PEIS, evaluate the mitigation of seriously harmful envi-

[3] "Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2001," EPA 430-R-03-004, April, 2003. http://yosemite.epa.gov/oar/globalwarming.nsf/content/ResourceCenterPublicationsGHGEmissionsUSEmissionsInventory2003.html. Note that these numbers overstate the actual chlorine mass in these emissions, but they exclude less destructive substitute compounds.

ronmental consequences through the development and deployment of alternative solid rocket propellants.

Perchlorate Releases

In 1990, when I wrote my report, "No Free Launch,"[4] I focused on the exhaust emissions from solid rocket motors. For the past several years, however, another environmental catastrophe, the pollution of our nation's drinking water with perchlorate, has emerged as a comparable challenge. As many as 20 million people are today drinking water containing perchlorate from rocket fuel production, and hundreds of wells have been taken out of service to avoid further public exposure.

Even in low concentrations, perchlorate in drinking water and food poses a threat to public health, particularly for newborns and other young children. U.S. EPA explains:

> Perchlorate interferes with iodide uptake into the thyroid gland. Because iodide is an essential component of thyroid hormones, perchlorate disrupts how the thyroid functions. In adults, the thyroid helps to regulate metabolism. In children, the thyroid plays a major role in proper development in addition to metabolism. Impairment of thyroid function in expectant mothers may impact the fetus and newborn and result in effects including changes in behavior, delayed development and decreased learning capability. Changes in thyroid hormone levels may also result in thyroid gland tumors. EPA's draft analysis of perchlorate toxicity is that perchlorate's disruption of iodide uptake is the key event leading to changes in development or tumor formation.[5]

Rocket fuel wastes, from manufacturing, testing, training, maintenance, and decommissioning are a significant environmental hazard. This is a front page news story from California to Massachusetts, but it is barely mentioned in the PEIS.

Where it is mentioned, the authors understate the risks of exposure:

> It is now known that perchlorate's direct effects on the human body are limited to the thyroid gland, and only if ingested at very high levels for a prolonged period of time (typically years). Peer-reviewed studies suggest that perchlorate in drinking water below 200 parts per billion has no measurable effect on human health. These findings provide reason to believe that low levels of perchlorate (below 200 parts per billion) also have no measurable effect on pregnant women or fetuses. (Council on Water Quality, 2003) Currently there are no Federal drinking water standards for perchlorate. (4-56)[6]

[4] Lenny Siegel, "No Free Launch: The Toxic Impact of America's Space Programs," National Toxics Campaign Fund, August 1, 1990.

[5] "Perchlorate: Frequently Asked Questions," U.S. EPA, August 5, 2004. http://www.epa.gov/safewater/ccl/perchlorate.html

[6] Note: The cleverly named Council on Water Quality is an association of companies that have released perchlorate pollution into the environment, not a government agency or an unbiased observer.

The reason that there is no federal drinking water standard for perchlorate is that the Defense Department objected to EPA studies that suggested a standard of one part per billion (ppb). Meanwhile, regulatory agencies are using levels far below the 200 ppb asserted in the PEIS. On the way to establishing its own legal standard, California has adopted a Public Health Goal of 6 ppb.[7] In May, 2004, Massachusetts identified a reference dose for perchlorate that would correspond to a 1 ppb drinking water exposure limit. It too is close to promulgating a binding standard.[8] And while U.S. EPA will not promulgate a standard until after the National Academy of Sciences has completed its review, in the interim it has instructed its personnel to use an action level range of 4 to 18 ppb.[9]

The PEIS should offer estimates of the quantities of solid rocket fuel that will be manufactured for the BMDS, not just for testing, but for missiles that will be deployed and hopefully never be launched. From that figure, it can estimate the quantities of manufacturing waste—propellant flakes, chips, and wastewater—likely to be generated. The PEIS estimates that the BMDS program will launch 413 solid-propellant rockets, containing from under 500 kilograms (1,102 pounds) to 60,000 kilograms (132,277 pounds) of solid propellant each. About 70% of that propellant, by weight, will consist of ammonium perchlorate. But nowhere does it estimate what quantity of propellant will be contained in deployed missiles, or even how many missiles will be part of that system. Without that information there is no way to project the amount of propellant waste likely to be generated by the program.

Propellant Disposal

Disposal of missile propellant, for both refurbishing and decommissioning, is a significant financial and environmental cost. NEPA provides the opportunity to weigh those costs before system acquisition, so technological choices that minimize such costs can be considered. The Government Accountability Office (formerly the General Accounting Office) wrote:

> DOD regularly disposes of missiles and has an amount for disposal costs included in its annual budget request. Thus, because it is known at the time of acquisition that costs will be incurred for missile disposal, the probability criterion for recording a liability is met. The Congress has also recognized that disposal costs will be incurred and has emphasized the importance of accumulating and considering this information. For example, the National Defense Authorization Act for Fiscal Year 1995 requires the Secretary of Defense to determine, as early in the acquisition process as feasible, the life-cycle environmental costs for major defense acquisitions programs, including the materi-

[7] "Frequently Asked Questions (FAQs) About the Public Health Goal for Perchlorate," California Office of Environmental Health Hazard Assessment (OEHHA), March 11, 2004. http://www.oehha.ca.gov/public_info/facts/perchloratefacts.html

[8] "Perchlorate: Toxicological Profile And Health Assessment," Massachusetts Department of Environmental Protection, Office of Research And Standards, Final Draft, May, 2004. http://www.mass.gov/dep/ors/files/perchlor.pdf.

[9] Marianne Lamont Horinko, Assistant Administrator, "Memorandum: Status of EPA's Interim Assessment Guidance for Perchlorate," U.S. EPA, January 22, 2003. http://www.safedrinkingwater.com/community/2003/021203perchlorate_memo.pdf

> als to be used and methods of disposal. The life-cycle cost estimates are required before proceeding with the major acquisition.[10]

Solid rocket fuel, when deployed in missile systems, does not last indefinitely. It has a shelf life. Both strategic and tactical missiles must be de-fueled and re-fueled or replaced periodically. By 2009, the Army will need to demilitarize over 102,000 Tube-launched, Optically-tracked, Wire-Guided (TOW) tactical anti-tank missiles, and by 2015 over 306,000 Multiple Launch Rocket System (MLRS) rockets will also require demilitarization. These weapons contain over 45,000,000 pounds of ammonium perchlorate, as well as nearly 1,200,000 pounds of RDX and HMX, two other energetic contaminants.[11]

Other missiles become obsolete and require replacement. The Navy reportedly destroyed more than 350 Poseidon Sea-Launch Ballistic Missile second stage motors, each containing 17,000 pounds of solid propellant—about 6,000,000 pounds total—at Hill Air Force Base in Utah, and it is scheduled to be about a third of the way into the destruction of 800 larger Trident I rocket motors.[12]

GAO did not separate disposal requirements for refurbishing from disposal for decommissioning. In 1998, it tabulated over 574,000 missiles and 5,871 large solid rocket motors in the Defense Department inventory, most of which would require disposal.[13]

Yet the PEIS appears not to address the environmental aspects of missile maintenance and it gives only cursory mention to decommissioning:

> Decommissioning of missiles would first require the removal and proper disposal of liquid, solid, or hybrid (liquid and solid combination) propellants from the booster(s). Where possible, propellants would be recovered and reused. Aging motors that contain flaws would likely be decommissioned using open detonation.... Solid rocket propellant would be removed for reclamation or burning in a controlled environment, such as an incinerator. Where practicable, incineration or closed burning of rocket propellant would be performed. Most of the acid and particulates ejected during the burn would be collected in plume scrubber water. This water would be treated for acceptance by a publicly owned (or federally owned) water treatment works in accordance with a National Pollutant Discharge Elimination System (HPDES) permit. (p. 4-16)

Once again, the PEIS authors don't seem to be reading the newspapers. The disposal of solid rocket propellant through "hog-out" (washing out the propellant) or open burning/open detonation are some of the major sources of perchlorate contamination across the country. The

[10] "Financial Management: DOD's Liability for Missile Disposal Can Be Estimated," U.S. General Accounting Office, GAO/AIMD-98-50R, January 7, 1998, page 6.

[11] "Reusing and Disposing of Missile Munitions: Phase 2," U.S. Army Audit Agency, AA 02-145, February 25, 2002, pages 20-21.

[12] "Hill AFB to Destroy 800 Trident Motors, Project Expected to Last 17 Years," *Defense Cleanup*, June 19, 1998, page 4.

[13] "Financial Management," page. 8.

PEIS should note how much propellant will be used, how often it will be necessary to dispose, and what the environmental impacts of each disposal or treatment method are likely to be. Such information is necessary, not just to estimate the life-cycle costs of the program, but also to figure out in advance how to reduce financial costs and environmental impacts through system redesign or ongoing mitigation activities. That's the purpose of the NEPA process.

To its credit, the Defense Department has developed better technologies for treating and recycling solid rocket propellant. For example, the Army Aviation and Missile Command's Research, Development, and Engineering Center uses super-critical ammonia to process and reclaim the ammonium perchlorate from solid propellant. The Hawthorne Army Depot, Nevada, has installed a prototype biodegradation system processing wastewater containing ammonium perchlorate.[14]

However, the Defense Department does not currently have the capacity to dispose of its current missile demilitarization and disposal inventory by any method, let alone the dispose of solid-propellant in an environmentally sound manner.

- Thermal treatment can release dioxins into the atmosphere. Even at very low concentrations, these compounds are a global, persistent threat to public health.
- Open burning and detonation often releases perchlorate into soil and groundwater.
- Recycling means that significant quantities of perchlorate are likely to be used in construction and mining. However, evidence is emerging—from Westford, Massachusetts, for example—that such uses may be generating unacceptable levels of pollution, as well.[15]
- Treatment systems installed to date lack the capacity to treat all the solid or liquid wastes likely to be generated by BMDS manufacture, maintenance, and decommissioning.

Overall, the PEIS puts off consideration of the challenge of waste decommissioning, stating, "The environmental impacts associated with decommissioning of specific components would be more appropriately addressed in subsequent tiered environmental analysis..." (ES-20)

This is unacceptable. It can only lead to "end-of-pipe" solutions, even though the Defense Department's own environmental managers and specialists agree that environmental protection should be integrated into acquisition and even research and development. The 2001 Munitions Action Plan, for example, states:

> The current emphasis in acquisition of munitions of all types (air delivered, ground launched, and sea launched) is on improving accuracy, reliability and increasing distances between firing or launch points and targets (i.e., so-called standoff ranges). At the same time, the public and regulatory bodies are rais-

[14] "Joint Demilitarization Technology Program," Department of Defense, October, 2003. http://www.dtic.mil/biosys/org/demil_rept2003_final.pdf

[15] Carrie Simmons, "DEP: Westford 'Responsible' for Water Clean-Up," *Westford Eagle* (Massachusetts), September 30, 2004.

> ing concerns about explosives safety and the environmental effects of munitions. The DoD is also becoming more aware of the cleanup and environmental compliance costs associated with training, testing, demilitarization, and unexploded ordnance (UXO) responses.
>
> These developments have highlighted the need for DoD to address environmental and safety concerns, and costs, throughout the munitions life cycle. This cycle starts from the technology development and design phase to the end-state of use, UXO and munitions constituents cleanup on ranges, or demilitarization. Addressing these concerns early in the life cycle (during requirements definition and acquisition) has the potential to significantly reduce costs and avoid problems later.[16]

That is, if the review of the potential environmental impacts of a system such as the BMDS finds the potential for significant negative environmental impacts, then those designing the system, selecting programmatic alternatives, and managing its testing and deployment should continuously evaluate ways to minimize those impacts, from the beginning.

The PEIS should consider the environmental consequences of various disposal strategies so the BMDS program can develop the technology or capacity to address its waste or consider the use of alternative launch technologies or strategies to minimize either the waste or the negative environmental impacts.

Perchlorate Debris

The PEIS raises and then dismisses the potential environmental impacts from perchlorate debris from launch failure. Presumably the same issues arise if a missile is intercepted before burning all its fuel. It states:

> During flight termination or catastrophic missile failure of solid propellant boosters, pieces of unburned propellant could be dispersed over an ocean area of up to several hundred kilometers. Once in the water, ammonium perchlorate could slowly leach out and would be toxic to plants and animals. In freshwater at 20° C (68° F), it is likely to take over a year for the perchlorate contained in solid propellant to leach out into the water. (Lang et al, 2000, as referenced in U.S. Army Space and Missile Defense Command, 2003) Lower water temperatures and more saline waters would likely slow the leaching of perchlorate from the solid propellant into the water. Over this time, the perchlorate would be diluted in the water and would not reach significant concentrations. (U.S. Army Space and Missile Defense Command, 2003) (page 4-51)

The PEIS authors apparently not followed carefully the research of the Aerospace Corporations team, headed by V.I. Lang, mentioned in their text. This group, which has been

[16] *Munitions Action Plan: Maintaining Readiness through Environmental Stewardship and Enhancement of Explosives Safety in the Life Cycle Management of Munitions,* U.S. Department of Defense Operational and Environmental Executive Steering Committee for Munitions (OEESCM), November, 2001, page 16.

studying perchlorate releases from launch operations for the Air Force, concluded in their most recent report:

> As illustrated by our hypothetical case study, risks associated with the inadvertent release of perchlorate from accidental launch failures must be managed on a case by case basis because of the complexity of variables that can affect the release rate from propellants, and because each launch location has unique environmental characteristics. The same type of approach can be used to assess the risk of perchlorate releases from other operations where sold propellant may be dispersed.
>
> We recommend that a systematic approach to assessing potential impacts be used in the initial planning stages of a launch program, for example, in the AF Environmental Impact Analysis Process, which complies with the National Environmental Policy Act (NEPA). Regulatory agencies may require such analyses be performed prior to new launch programs. In this report, we have presented one type of step-wise approach to assessing perchlorate releases for a typical launch scenario.
>
> Initial studies performed by the University of Alaska on fish exposed to solid propellant in water samples, and in particular on fish exposed to perchlorate in water, indicate the potential for significant biological effects. Studies are also under way to determine the effect of released perchlorate on soil and plant species.[17]

The Army should follow the advice of the Air Force contractors and conduct site-specific analysis of the impact of perchlorate debris on any freshwater lake that might receive perchlorate debris as well as confined oceans waters, such as within the Marshall Islands, where repeated releases of perchlorate could damage sensitive ecosystems or essential food supplies. It should also work with NASA and the Air Force to ground-truth models on perchlorate releases by conducting actual water, soil, and sediment sampling for perchlorate at major launch facilities such as Cape Canaveral and Vandenberg Air Force Base.

Conclusion

To ensure maximum environmental protection and reduce known, widespread human health risks from the use and disposal of solid rocket propellant if the Ballistic Missile Defense System moves forward, the Programmatic Environmental Impact Systems for the Ballistic Missile Defense System should compare the proposed alternatives against a genuine No Action Alternative. At a minimum, to comply with the National Environmental Policy Act, it should::

[17] V.I. Lang et al, "Assessment of Perchlorate Releases in Launch Operations III," The Aerospace Corporation (No. TR-2003(1306)-2, prepared for the Air Force Space Command Space and Missile Systems Center (SMC-TR-04-11), September 18, 2003, page 27. This and other valuable Air Force/Aerospace Corporation studies on the likely environmental impacts of space launches may be found at http://ax.losangeles.af.mil/axf/studies/studypage.htm.

1. **Provide more detailed estimates of perchlorate waste likely to be generated by system development, testing, deployment, maintenance, and decommissioning *and* acknowledge emerging regulatory standards for perchlorate exposure.**

2. **Consider in detail the management practices—launch protocols, treatment technologies, etc.—necessary to mitigate the significant environmental impacts, including increased depletion of the stratospheric ozone layer and the likely release of perchlorate into groundwater, surface water, and soil.**

3. **Evaluate alternative launch technologies not based upon ammonium perchlorate.**

Based upon such additional environment review, which I believe is mandated by any fair reading of the National Environmental Policy Act and its implementing regulations, Program Managers should use the information generated to help evaluate all alternatives and to mandate actions to minimize or mitigate the serious environmental consequences associated with such a large and continuing use of solid rocket propellant. Such steps are necessary to protect the American people, the ostensible purpose of the Ballistic Missile Defense System.

Missile Defense Agency, c/o ICF Consulting

Re: Ballistic Missile Defense System,
Draft Programmatic Environmental Impact System

I am here on behalf of Sacramento Area Peace Action and our 4,000 supporters, both to comment on the PEIS, and to register a complaint with the manner in which this hearing was scheduled. There has been no widespread publicity in California that we are aware of regarding this hearing today in Sacramento. Is this some sort of stealth strategy to limit public input on this crucial issue? We question if a Draft PEIS can be legitimate if there is not adequate notice of the document and the hearings on this matter.

What is most disturbing, however, is that the current administration is forging ahead with deployment of the first two interceptors for the BMDS, at Ft. Greely, Alaska, making a mockery of these hearings. And it is even more perplexing that the interceptors that were just installed have not yet been tested in this system! The tests have been continually postponed, and the Pentagon's chief weapons evaluator has said these interceptors may only be capable of hitting their targets about 20% of the time!

Why is our government spending billions of dollars and risking the beginning of a new nuclear arms race on a so-called missile shield with such an abysmal record?

The greatest danger we face is not from intercontinental ballistic missiles carrying nuclear warheads to our shores, but of re-igniting the nuclear arms race and motivating countries that fear us to attempt illegal acquisitions of nuclear weapons. They see that the technology for a missile defense system can also be used offensively against them. Their defense against our military superiority would be to either produce many nuclear ballistic missiles, to overwhelm our TWENTY-PERCENT system, or to use secret delivery systems – weapons smuggled into our country or delivered by short-range missiles launched just offshore.

Forging ahead with the Missile Defense System will also create terrible consequences: pollution from rocket launches, space debris, and accidents within the system or involving civilians. Other groups are scheduled to testify more comprehensively on these environmental hazards. But I am emphasizing here that all people on earth, not just Americans, face grave environmental threats from this drive to dominate the world by dominating space. The environmental pollution may kill us slowly, if we don't do it quickly with a nuclear war.

Thus the greatest environmental impact of the MDS will be to make our entire planet more dangerous to all forms of life, and we Americans are more vulnerable, not safer.

Most Americans consider a nuclear war unthinkable, but apparently our leaders and Congress do not. It is astounding to see the turnaround on proliferation and new nuclear weapons in this administration. Will threatening other nations encourage them to cooperate with the Non-Proliferation Treaty? Will the U.S. violations of the Treaty persuade other nations to embrace non-proliferation? We think not.

Similarly, the abrogation of the Anti-Ballistic Missile Treaty last year by this administration, in order to pursue this fantasy "missile shield" will not promote international cooperation on disarmament.

We can only conclude that this rush to further develop and deploy this ill-conceived "missile defense" shield is driven by ideology and politics, and fueled by the greed for profits from this costly boondoggle. That is what it is, a boondoggle. The leading scientists and Nobel Prize laureates have condemned this as unworkable and dangerous to global security, but this administration rushes headlong into a hasty deployment. The term coined to characterize this drive is "a rush to failure."

In conclusion, we at Sacramento Area Peace Action condemn the alternatives 1 and 2, with the extreme threat they pose to our nation and the world.

We would support the "No Action Alternative," if there had been a legitimate attempt at researching and weighing a true alternative of "no action." Such a proposal should have encompassed a suspension of research and development, no testing, and no initial deployment. It should have evaluated the cost-effectiveness of vigorous pursuit of international cooperation on nuclear disarmament. As it stands, the "No Action Alternative" does not meet the requirements of the National Environmental Policy Act.

For this reason, we consider this draft PEIS inadequate and insufficient for proceeding with the BMDS.

For the Board of Directors,

Winnie Detwiler

Winnie Detwiler

DC_PHW0006

Statement from MacGregor Eddy, advisory board member Global Network Against Weapons and Nuclear Power in Space Regarding the Programmatic Impact Statement (PEIS) for the Ballistic Missile Defense System (BMDS) Oct. 19, 2004 Sacramento California.

1. The 515 projected BMDS launches that are evaluated by the PEIS do not include the intended expansion of the BMDS program, and thus does not meet criteria of the National Environmental Policy Act (NEPA). This intended expansion was described on October 13 by General Henry "Trey" Obering the director of the Missile Defense Agency (MDA). Speaking at the Homeland Security Conference in Colorado Springs General Obering was asked about the new Theater High-Altitude Area Defense (THAAD) missiles scheduled to move into production in late 2005. In response General Obering stated they will ***"augment, not replace, the current generation of ground-based midcourse interceptors. In fact, there will be a continued spiraling up of capabilities in both missile networks, with more missiles and additional sites being added for the current missiles, and an expansion of THAAD beyond the initial scheduled 25 missiles"***

2. The PEIS does not evaluate the environmental impact of the ***no action*** alternative, and thus does not comply with the intent of the National Environmental Policy Act. Without this evaluation there is no way to compare the environmental impact of the program to the impact of the ***no action*** alternative, and thus violates both the letter and the spirit of NEPA.

3. The PEIS does not address the environmental impact of the response to BMDS by other countries. For example, China is planning to increase the number of missiles they have in direct response to the BMDS deployment. The development, testing, deployment and de-commissioning of these missiles in China will impact the global biome.

Missile Defense Agency BMDS PEIS
c/o ICF Consulting
9300 Lee Highway
Fairfax, VA 22031

Dear Friends,

Women's International League for Peace and Freedom (WILPF) submits the following initial comment on the current draft Programmatic Environmental Impact Statement of the Missile Defense Agency.

WILPF is a ninety year old non-governmental organization that has worked tirelessly since its inception to put an end to war. WILPF has supported the development of international institutions and international law, and non-violent methods of conflict resolution that together can facilitate the co-existence of diverse nations and peoples on this planet.

We hope the comments of ourselves, and of others who oppose the militarization of space, will be considered seriously, and that both environmental concerns and concerns for the future of our human race will lead to suspension of this ill-advised and destabilizing missile defense program.

The MDA draft PEIS seeks to answer to detrimental environmental effects of three alternative development plans for Ballistic Missile Defense. We have found the answers disturbingly incomplete. We have also carefully considered all three alternatives presented and have concluded that it would be dangerous – and indeed disastrous -- for the future of our nation to proceed with any of them. It is impossible to comment on all the details in the 701 page document in this short space, but we expect to submit several supplementary comment papers on a few of the many issues of deep concern to us.

First, we are convinced that Alternative 2, which inclu[illegible] of space based interceptors, is completely unacceptable. We will subr[illegible]mments on both the issue of debris from experiments with space b[illegible]d on the development of laser weapons. We have other concerns re Alternative 2 that you will perhaps argue are beyond the scope of this PEIS, but that makes them no less important. One is the creation of orbiting debris in space which will remain there

DC_PHW0008

as a threat to future space exploration. The second of these is that space based laser interceptors will be a first step toward the more ambitious program of space weaponization already developed by the Pentagon and the Space Command, and presented in detail in the November, 2003 *U S. Air Force Transformation Flight Plan*. This is a direction in which no civilized nation should proceed!

We believe that Alternative 1, which does not include space based weapons, and Alternative 3, which is unclear on this point, are also unacceptable, even from a solely environmental viewpoint. We are concerned about the adverse effects in all of the resource areas discussed in the MDA PEIS including hazardous waste, legal restraints, decommissioning of the weapons systems, destruction of the ozone layer, global warming and rocket fuel pollution of our water and river systems. We are preparing supplemental comments on at least some of these concerns.

We also wonder why this expensive and almost certainly unachievable missile defense program has been developed in the first place. It does not answer to probable threats to our national security in the present or in the coming decade. It will do nothing to prevent terrorist attacks, and there is now no hostile country or group with the capability of firing inter-continental ballistic missiles at the United States. Missile defense seems rather to be preparation for future confrontation with the only two countries really capable of threatening our current military domination or challenging us with nuclear attack. Neither of them – China or Russia – is currently an enemy, but this aggressive program may well push them into organizing allies and forces against our own threat of global – and planetary -- domination.

With this in mind, we will submit an additional comment on what we consider to be the only feasible alternative approach to protection of our land and peoples from intercontinental ballistic missiles, from the ravages of nuclear, biological or chemical warfare – or, indeed, from either attacks by small bands of terrorists or from what we have come to call "conventional warfare" (e.g. our own recent "shock and awe" attack on Baghdad).

This Alternative 4 would include a return to the United Nations disarmament treaty process (which the current Administration is regrettably blocking), and assumption of a lead role in the continual development of enforceable and universally applied international law consistent with both the UN Charter and the Universal Declaration of Human Rights. The United States would re-enter that process as the most powerful and most militarized nation in the world and would have no substantial military rivals. This is a rare and critical moment in history and the choice is ours: the United States can lead the way toward a world freed from war with sustainable development and human rights for all – or this nation can drag the human race backward with it into a world ruled by war, military domination and the threat (or use) of weapons more powerful than any known before.

For us in the WILPF there is no question about which route is preferable. We are convinced that continuing with any of these three BMD programs will make the step-by-step process of nuclear disarmament impossible, make war on earth and in space inevitable, and seriously threaten human existence and the entire fragile web of life on our unique and precious planet. We urge all those in the Pentagon, the Missile Defense Agency and in the aerospace corporations to join us in choosing life over death and step-by-step peace building over further destruction of this planet and its fragile web of life

Sincerely,

Sandy Silver, President
United States Section

DC_PHW0009

Public Comment Form
Public Hearing for the BMDS PEIS
Sacramento, CA – October 19, 2004

Dear Participant:

We want to hear from you. If you have comments on the Draft Ballistic Missile Defense System (BMDS) Programmatic Environmental Impact Statement (PEIS), please use the reverse side of this form to bring them to our attention. If more space is needed, please feel free to attach additional pages. For additional information on the BMDS PEIS please visit our web site at

http://www.acq.osd.mil/mda/peis/html/home.html

If you would like to be notified when the Final PEIS is available, request a hardcopy of the Executive Summary or CD-ROM of the entire document, please check the appropriate lines on the form below and verify the accuracy of your address. When you have completed your comments, you may either leave this form with a person at the registration table, or mail, fax or e-mail this form by November 17, 2004 to

Comment

1) THE PEIS APPEARS TO BE BIASED TOWARD MINIMIZING THE ENVIRONMENTAL IMPACT OF THE BOMBS. THERE IS AN INHERENT CONFLICT OF INTEREST IN THIS REPORT BEING WRITTEN BY THE DOE, WHICH HAS A STAKE IN THE BOMB'S PROJECT CONTINUING. AN INDEPENDENT ENVIRONMENTAL IMPACT REPORT SHOULD BE COMMISSIONED BY A NON-PARTISAN PANEL OF SCIENTISTS WITH EXPERTISE IN THE FIELD.

2) THE PEIS IGNORES THE OBVIOUS PROBABILITY THAT OTHER COUNTRIES WILL RESPOND TO THE BOMBS BY INCREASING THEIR OWN ICBM ARSENALS. THE ENVIRONMENTAL IMPACT OF A WORLDWIDE INCREASE IN ICBM'S SHOULD BE CONSIDERED, INCLUDING THE INCREASED POSSIBILITY OF ACCIDENTAL ~~[illegible]~~ [illegible] COUNTRY'S SCIENTISTS [illegible] IN [illegible].

3) THE PEIS DOES NOT CONSIDER THE POSSIBILITY THAT THE DEVELOPMENT & DEPLOYMENT OF SPACE BASED WEAPONS BY THE U.S. IS LIKELY TO STIMULATE SIMILAR PROGRAMS BY OTHER COUNTRIES AND INCREASE THE CHANCE OF ACCIDENTAL OR PURPOSEFUL DETONATIONS IN SPACE, INCLUDING SOME INTENDED FOR CIVILIAN PURPOSES.

4) THE "NO ACTION ALTERNATIVE" IS NOT TREATED SERIOUSLY, AS EVIDENCED BY THE ABSENCE OF THE WORLDWIDE ELIMINATION OF ICBM'S THROUGH DIPLOMATIC MEANS [illegible] INTERNATIONAL [illegible] EFFORTS, INCLUDING [illegible] [illegible] OF UN ARMS INSPECTIONS.

K.4.2 Responses to In Scope Comments

Exhibits K-2 (*Responses to Comments – BMDS and Components*), K-3 (*Responses to Comments – Environmental Impacts*), K-4 (*Responses to Comments – Miscellaneous*), and K-5 (*Responses to Comments – Proposed Action and Alternatives*) contain responses to various comments. Each exhibit outlines the issue topic, comment number, excerpt text, and MDA's response. Please note that some comment excerpts address the same issue and to reduce the redundancy in the table, the appropriate response is printed only once and the remaining comment responses for that issue refer to that response. Note that comment text was extracted verbatim from the submitted comments.

Exhibit K-2. Responses to Comments – BMDS and Components

Issue Topic	Comment Number	Excerpt Text	Response
BMDS and Components	E0162-8	6) The PEIS contains a short discussion of future laser weapon systems (page F-7) and the Tactical High Energy Laser (page F-9). It notes that testing of a laser demonstrator began in 2000. The PEIS should review these tests and testing plans for other high-power laser weapons and other directed-energy weapons. An article in the 18 Dec. 2002 Jane's Defence Weekly indicated that a megawatt-class free-electron laser could be tested at PMRF in two to three years.	As indicated Section F of the PEIS discusses those advanced systems that MDA is monitoring for maturation of technology and potential application and integration into the BMDS. The PEIS describes the proposed BMDS components and testing activities in sufficient detail to facilitate a programmatic analysis of the potential impacts. The PEIS is intended to serve as a tiering document for future site- and component-specific analyses. If future plans identify specific locations that are required to support laser activation tests, they would be considered in subsequent tiered NEPA analyses.
BMDS	E0030-1	8) Unless the offensive missiles are sensed on launch and destroyed during boost, the dirty bomb effects will rain on the targets anyway; and the proposed system is not designed to intercept during boost.	The BMDS is envisioned to be capable of defending against all classes of threat ballistic missiles in all phases of flight (i.e., boost, midcourse, and terminal). Currently configured or planned BMDS elements that would defend in the boost phase include the Airborne Laser (ABL) and Kinetic Energy Interceptor (KEI).
BMDS	E0162-7	5) The PEIS has no discussion of the unresolved safety issues involving Strategic Target System and THAAD launches at PMRF which I noted in my scoping comments (second comment on page B-15). No detailed hazard	There are inherent risks with any missile testing activity; however, protection of life and property, on and off range, is the prime concern of Range/Mission Safety personnel. The Range Commanders' Council (RCC)

Exhibit K-2. Responses to Comments – BMDS and Components

Issue Topic	Comment Number	Excerpt Text	Response
		areas have been shown for Strategic Target System launches at azimuths other than 280 degrees. Similarly, no diagrams showing the THAAD hazard area were given in the 2002 THAAD EA and no detailed analysis was cited to justify the reduction in the hazard area radius from 20,000 feet in the 1998 PMRF EIS to 10,000 feet in the THAAD EA. There can be no meaningful public evaluation of the risks of such launches without this information.	Common Risk Critieria for National Test Ranges (RCC 321-02) sets the requirements for minimally acceptable risk criteria for occupational and non-occuptational personnel, test facilities and nonmilitary assets during range testing operations. Under RCC 321-02, individuals of the general public shall not be exposed to a probability of fatality greater than 1 in 10 million for any single mission and 1 in 1 million an an annual basis. Range safety personnel also apply launch window criteria that consider various weather and climatic conditions as appropriate. However, this PEIS is intended to provide a programmatic analysis of the potential impacts associated with the development, testing, deployment, and decommissioning of the BMDS. The PEIS is not a site or component-specific environmental analysis, and therefore does not provide specific information about particular components or their operation at various facilities.
BMDS	E0162-10	8) In 2002 the Defense Dept. announced that it would classify details about missile defense tests that had previously been public information. How can the public and independent technical analysts assess the impacts of tests and judge the effectiveness of BMDS components if this information is unavailable? Similarly, how can one estimate the impacts of entirely secret programs?	The PEIS provides sufficient technical information on the BMDS to enable both the technical analyst and a member of the general public to conduct a programmatic analysis of the environmental impacts potentially associated with the development, testing, deployment, and decommissioning of the BMDS. For specific technical information please see Volume 1 and Volume 2 - Appendices D, E, and F of the PEIS. The BMDS components, functions and activities are adequately explained and evaluated in the PEIS, but specific test results measuring system effectiveness are not necessary

Exhibit K-2. Responses to Comments – BMDS and Components

Issue Topic	Comment Number	Excerpt Text	Response
			for assessing the potential environmental impacts of implementing the BMDS.
BMDS	E0162-15	13) The example test scenario on page 2-13 involves use of the Cobra Dane radar. However, the August 2003 GAO report GAO-03-600 noted that there were no plans to test this radar using BMDS targets. Are such tests now planned in the next ten years?	The reference in Section 2 to the use of the COBRA DANE radar is an example test scenario and is not meant to refer to a specific test scenario. However, since the publication of the Draft PEIS, the COBRA DANE radar did participate in tracking BMDS target missiles in September 2005. The PEIS provides a programmatic review of the proposed BMDS and is not intended to address the potential environmental impacts of specific tests. Specific test scenarios can only be analyzed in subsequent environmental documentation, as appropriate. It also should be noted that the GAO report was published in 2003 and therefore may not contain the most up-to-date information regarding current plams for using or including BMDS assets in specific tests.
BMDS	E0162-16	14) The details of integrated flight test events are characterized as "only conceptual at this time" on page 2-50. Some test scenarios examined in the 2003 GMD ETR EIS had jet routes between Hawaii and the West Coast crossing the target and interceptor debris areas. What details about these tests will be made available for public evaluation?	The test scenarios examined in the 2003 Ground-Based Midcourse Defense Extended Test Range (GMD ETR) EIS, as well as those discussed on page 2-50, are representative of the range of potential test scenarios envisioned by MDA test planners and show that coordination with the Federal Aviation Administration (FAA) and other agencies would be required because air traffic potentially could be affected by target and interceptor debris. This PEIS process affords the public the opportunity to provide input on the types of environmental impacts potentially associated with testing various components and integrated system testing. This PEIS is not a site or component-specific environmental

Exhibit K-2. Responses to Comments – BMDS and Components

Issue Topic	Comment Number	Excerpt Text	Response
			analysis, and therefore does not provide specific information about particular components or their operation at various facilities. As specific test requirements become known, site/test-specific NEPA analyses will be prepared, appropriately tiered from this PEIS. If range or air traffic safety concerns arise regarding specific tests, MDA would identify airspace activities that need to be coordinated with the FAA to issue Notices to Airmen (NOTAMs) prior to those specific tests.
BMDS	E0162-17	Section D.2 has a brief discussion of land-based and sea-based Kinetic Energy Interceptors (KEI) for use as possible components of a boost-phase defense. It should be noted that a study of possible boost-phase defenses -- including surface-based and space- based KEI -- found that they would have limited capability against liquid-fueled ICBMs and were unlikely to be practical against solid-fueled ICBMs. This study was done by an American Physical Society study group and was released in July 2003. It is available at www.aps.org/public_affairs/popa/reports/nmdO3.cfm	These comments have been noted for the record. The PEIS does not address DoD threat assessment policy-making or the technological feasibility of missile defense system design.
BMDS	E0319-4	6. Include detailed information on High-Powered Microwaves ('Directed Energy') will be used as part of the BMDS and the environmental hazards associated with their transmission into the atmosphere and ionosphere (include human Electromagnetic Radiation (EMR) hazards)	The commenter's concerns are unfounded. No electromagnetic (EM) phased array or microwave radars are currently located at Kodiak Launch Complex (KLC). Additionally, no radars or radios located at KLC approach a power output in the range of 1.9 megawatts (MW). The existing radars include very high and ultra high frequency (UHF) radars with power outages ranging between 0.5 MW to 1 MW.
BMDS	E0319-13	The Draft PEIS did not give enough detail on the variations of BMDS 'Directed Energy' weapon systems in	See previous response.

Exhibit K-2. Responses to Comments – BMDS and Components

Issue Topic	Comment Number	Excerpt Text	Response
		Appendix F-'Advanced Systems' (e.g. high-powered microwaves), or proposed ground-based test locations. All proposed plans should be included in the PEIS for directed energy weapons. A high-power 'electromagnetic' phased array radar network is located on Kodiak Island, Alaska, but the MDA has refused to acknowledge its existence or purpose in all previous Kodiak Launch Complex Environmental Assessments since 1999 (when the microwave system started operating). The microwave's 1.9 Mega Watts (MW) of power has the potential to be used as a BMDS weapon by turning on its high power and directing it at a target or missile, thereby disabling the target's electronics and/or 'heating' up the target and causing it to explode in flight. The U.S. Air Force has received funding for several years for its 'Directed Energy' or 'Electromagnetic Warfare' program (which includes high-powered microwave systems). It is time for the MDA to 'declassify' the program and acknowledge the Kodiak microwave and explain how it will be used in BMDS testing and the human health hazards to Kodiak Island residents from the electromagnetic radiation (EMR) when the microwave is operating.	
BMDS	E0319-17	BMDS Draft PEIS Volume 2, Page D-27-Deployment; MDA proposed plans for 2004-2005 include as many as 16 interceptors (GBI) at Fort Greeley, Alaska and 4 interceptors at Vandenberg AFB, California; However, no mention is made regarding the number of interceptors at the KLC. Why not? Are missile silos being proposed for	The GMD ETR EIS did analyze the environmental impacts of launching interceptors from KLC. As the commenter correctly states, the MDA announced in a Record of Decision (ROD) that there were currently no plans to launch interceptors from KLC. This is still the case. The information presented in Appendix D has

Exhibit K-2. Responses to Comments – BMDS and Components

Issue Topic	Comment Number	Excerpt Text	Response
		Kodiak Island? If so, how many? If not, state the launch method.	been corrected in the Final PEIS to reflect that there are currently no plans to launch interceptors from the KLC.
BMDS	E0319-26	Another area of concern that is mentioned in the Draft PEIS, is the MDA's current testing of Israel's 'Arrow Weapon System' in the United States. The October 24, 2003 'Arrow System Improvement Program (ASIP) Environmental Assessment' (EA), discusses the MDA testing of the system over a 4 year period, with "targets being launched from either the Mobile Launch Platform in the Point Mugu Sea Range or Vandenberg AFB". According to the Arrow System EA, the Arrow interceptor would intercept a "liquid-fueled target system (LFTS) that uses a main liquid fuel, an oxidizer, and an initiator fuel for vehicle motor ignition and propulsion". The EA further states: "the Arrow interceptor missile is a two-stage vehicle launched from a six-pack mobile launcher. The missile contains approximately 1,670 kilograms (3,600 pounds) of solid rocket propellant in the booster. The interceptor with the propellant has a hazard classification of 1.3 and consists of hydroxyl terminated polybutadiene (HTPB), ammonium perchlorate, and aluminum powder. The interceptor also contains an optical (infrared) seeker and a radar sensor. The payload includes a focused blast-fragmentation warhead, with a hazard classification of 1.1D. Combined, the Arrow interceptor missile with its payload has a hazard classification of 1.1." Considering the Arrow interceptor missile has a Hazard class of 1.3 ('mass fire') and the payload's warhead a Hazard class of 1.1 ('mass explosion'), the PEIS should include information on all potential ground-based hazards	The PEIS describes the proposed BMDS in sufficient detail to facilitate a programmatic analysis of the potential impacts of conducting integrated system testing. The PEIS is intended to serve as a tiering document for future site- and component-specific analyses. The Arrow System Improvement Program (ASIP) Environmental Assessment (EA) referenced by the commenter addressed the potential environmental impacts of the testing of the Arrow Weapons System Improvement Program. As future plans for testing the Arrow Weapons System are identified appropriate environmental analyses will be conducted. In addition the ASIP EA has been incorporated by reference in the Final PEIS.

Exhibit K-2. Responses to Comments – BMDS and Components

Issue Topic	Comment Number	Excerpt Text	Response
		(and locations) and space-based hazards from the Arrow 'interceptor' and exploding 'warhead' that will release chemicals and add to further air and land contamination if there is a launch accident (or even if there is not an accident). Also, list the name of the warhead in the PEIS. It should have been listed in the Draft. In fiscal year 2004, the ASIP "Caravan 2 would consist of two flight tests of the enhanced Arrow Weapon System at a U.S. test range (to be determined) against a threat-representative target at approximately full range" (BMDS Draft PEIS, Volume 2, page D-46). The October 24, 2003 'Arrow Weapon System Improvement Program EA'-Alternatives to the Proposed Action- Alternatives Not Carried Forward, states: "A number of candidate test ranges were examined, in addition to the Point Mugu Sea Range. All of the candidate test ranges were analyzed for various operational and technical considerations including safety, range availability, instrumentation, operational cost, and logistical support. At the conclusion of the evaluation, only the Point Mugu Sea Range met the ASIP test program requirements". This is contradictory with the statement in the Draft PEIS (Volume 2, page D-46), which states a U.S. test range '"would be determined" for the Caravan 2 flight tests. Since the release of the ASIP EA in 2003, the BMDS PEIS should include all updated plans to launch the Arrow	

Exhibit K-2. Responses to Comments – BMDS and Components

Issue Topic	Comment Number	Excerpt Text	Response
		interceptor missile from other test launch sites/locations (e.g. Reagan Test Site, Kwajalein Atoll, Aleutian Chain, Gulf of Alaska, Poker Flats Rocket Range, Fort Greeley, or the Kodiak Launch Complex). The fact that Israel does not have land available for 'interceptor' missile testing, does not justify the MDA's decision to bring and test another country's 'experimental' war weapons into the U.S, which will contribute to the pollution of U.S. oceans, drinking waters, air and land. Nor should the MDA be helping Israel by testing weapons that will then be shipped back to Israel to be used against its enemies in its 'religious' war, in order to further the 'Israeli Terminal Missile Defense' program. The United States should be doing what it can to negotiate peace rather than promoting war via another country. The wording is not much different in the excuse the MDA gives for testing the Arrow interceptor in U.S. territory- "Commitments to Israel would not be fulfilled, and the United States would not realize any benefits to its own Terminal Missile Defense test program from participation in the ASIP" (Arrow System Improvement Program EA, October 24, 2004).	
BMDS	E0395-9	Also, the relationship between NFIRE and space-based missile defenses, alluded to in the PEIS, should be clarified.	A description of the proposed Near-Field Infrared Experiment (NFIRE) risk reduction activities as they relate to the BMDS is provided in Appendix D, Section D.2 of the PEIS. The NFIRE experiment will allow the MDA to gather additional data about operations from space-based platforms including platforms that could be used to host space-based weapons.

Exhibit K-2. Responses to Comments – BMDS and Components

Issue Topic	Comment Number	Excerpt Text	Response
BMDS	E0395-14	Except for the largely historical discussion in Section D.3, the PEIS does not adequately describe AEGIS BMD operations, the large number of missiles involved, nor the locations where testing or training with those ships and missiles will be conducted, nor the environmental impacts of operational deployment with those ships or missiles.	Aegis Ballistic Missile Defense (BMD) operations are addressed in the PEIS to the same extent as other ballistic missile defense programs. As detailed in the PEIS the individual program elements while developed individually historically are now undergoing integration testing to provide a layered BMDS capable of destroying all ranges of threat missiles in all flight phases. Specific test locations and activities are not analyzed in the PEIS; however, MDA routinely considers all test activities, including those involving Aegis BMD as player or watcher, to determine and prepare the requisite level of NEPA analysis. MDA will continue to consider the environmental impacts of its testing programs tiering from the PEIS, as appropriate.
BMDS	E0395-15	The environmental impacts of the development, testing, training, and deployment of the proposed new, high-speed, Kinetic Energy Interceptors are not adequately addressed. In particular, the number and size of these large interceptors is not described nor are the types of propellants and chemicals involved.	The KEI program is described in Appendix D, Section D.2 of the PEIS. This program was in the earliest planning stages by the MDA and the U.S. Air Force (USAF) at the time of release of the Draft PEIS. The USAF Space and Missile Systems Center addressed the NFIRE in the Orbital-Sub-Orbital Draft EA. Preparation of environmental analysis for the KEI is in the planning stages. This PEIS includes sufficient information to facilitate a programmatic analysis of the potential impacts of a KEI interceptor. This affords the public the opportunity to comment on the types of environmental impacts potentially associated with typical testing early in the development and testing process.
BMDS	E0427-9 and E0439-9	Both the PAC-3 and Aegis Cruisers are included as components of the proposed BMDS Since the PAC-3 is a relatively short range system and is not designed for intercepting ICBMs, how many PAC-3 batteries will have	Issues surrounding the effectiveness of specific BMDS components, numbers of units required to provide a tactical advantage, and tactical operation are not germane to the analysis of the potential environmental impacts of

Exhibit K-2. Responses to Comments – BMDS and Components

Issue Topic	Comment Number	Excerpt Text	Response
		to be deployed to offer full protection for the American and allied cities and military bases. Are these within range of any civilian aircraft? How will they discriminate attacking aircraft from commercial and civilian aircraft? The MDA needs to consider how many civilians and US/allied military personnel will be accidentally killed by the BMDS.	implementing the BMDS. The PEIS is intended to provide a programmatic analysis of the environmental impacts potentially associated with the development, testing, deployment, and decommissioning of the BMDS, and it provides the framework for assessing the envelope of MDA activities considering an integrated BMDS and on a cumulative basis. The PEIS does not evaluate the deployment of the PATRIOT Advanced Capability-3 (PAC-3) at specific sites in the U.S. If the PAC-3 system is deployed in the future additional analysis will be conducted, as appropriate.
BMDS	E0427-10 and E0439-10	11) The PEIS provides conflicting information on the effects of the ABL on health and safety. The PEIS does not quantitatively assess the risk of the Airborne Weapons Laser (in a Boeing 747) blinding pilots and/or other civilians, stating mainly that humans and others would be exposed to the laser beam, mainly as reflected light for less than 0.01 seconds. However the PEIS provides no data on the wattage or power of these lasers in the PEIS making it impossible to assess the dangers of such laser exposure, especially to the eyes.	We disagree with the commenter's assertion that the PEIS provides conflicting information on the effects of the ABL on health and safety. The PEIS states that the ABL lasers are ANSI Class 4 lasers, and that the high energy laser is a megawatt class laser, the beacon illuminator laser and track illuminator laser are kilowatt (kW) range lasers, and the active ranging system operates in the range of 100 watts. The PEIS also addresses the potential impact of lasers on human health and the environment and acknowledges, for example, that severe damage to the fovea could occur if focused light energy were to strike the retina, but that the damage would be less severe if the eye were pointed somewhere off to the side rather than directly at the source. But as explained in the PEIS, the ABL would be tested in airspace areas that are appropriate for this type of activity and MDA test planners would follow all applicable guidelines and regulations, such as establishing restricted areas, displaying warning signs, designating restricted areas, clearing airspace during

Exhibit K-2. Responses to Comments – BMDS and Components

Issue Topic	Comment Number	Excerpt Text	Response
			tests, and removing reflective surfaces to ensure that the laser does not adversely harm health and safety. Thus, the PEIS describes the proposed BMDS and ABL in sufficient detail to facilitate a programmatic analysis of the potential impacts of the ABL on health and safety.
BMDS	E0427-13 and E0439-13	12) The MDA PEIS needs to consider whether boost phase BMDS interceptors could be launched erroneously, causing another country to believe it was under attack, and thereby triggering a nuclear war. The American Physical Society examined the issue of boost phase intercept, and determined that the interceptor has to be very close to the ICBM. be launched within about 15-60 seconds from the time the ICBM was launched, and have much greater accelerations than the ICBM http://www.physicstoday.org/vol-57/iss-l/p30.html (Kleppner et al. 2004). The problem of boost Phase intercept is greater for solid rockets with high accelerations than for slower accelerating liquid rockets. The further problem is that ship based interceptors are not big enough and do not have sufficient accelerations to make a boost phase intercept even from a small country like North Korea. If it did intercept, it is likely the warhead would not be destroyed by a kinetic hit-to-kill interceptor and would continue on to near its intended destination. Finally, they point out that a boost phase launch intercept of a ICBM from North Korea would likely occur over northern China, further risking causing China to think it was under attack by the US which could cause a nuclear war (Kleppner et al. 2004). The BMDS needs to consider the realities of the limitations of any	The BMDS is envisioned to be capable of defending against all classes of threat ballistic missiles in all phases of flight (i.e., boost, midcourse, and terminal). Currently configured or planned BMDS elements that would defend in the boost phase include the ABL and KEI. The ABL would be deployed to and operate in areas where boost-phase intercepts could be attempted. The PEIS describes the proposed BMDS including weapons that would defend in the boost phase, in sufficient detail to facilitate a programmatic analysis of the potential impacts. However, this PEIS does not address DoD threat assessment policy-making or the technological feasibility of missile defense design.

Exhibit K-2. Responses to Comments – BMDS and Components

Issue Topic	Comment Number	Excerpt Text	Response
		BMDS relative to a real no-action alternative of working toward disarmament through arms control treaties.	
BMDS	E0427-14 and E0439-14	13) Space debris from high altitude, mid-course missile intercepts or destruction of satellites. The PEIS does mention that even tiny particles of space debris traveling at extremely high speeds in orbit can destroy space suits, rockets and satellites. While the PEIS correctly points out that debris from low orbital intercepts will decelerate once it hits the atmosphere, and thereby de-orbit. However the PEIS fails to consider the space debris from high altitude intercepts which risk producing space debris that could make space unusable for many years. While the PEIS considers testing the BMDS on "targets of opportunity", no mention is made of space debris resulting if other nations target US BMDS satellites or components in high orbit as "targets of opportunity". This must be considered since the resulting space debris could destroy objects in space, making space unusable as well as violating the 1967 space treaty.	The PEIS considers the environmental impacts including the impacts from orbital debris from increasingly realistic testing scenarios including higher altitude and higher speed intercepts. Technical Appendix L has been added to the PEIS to provide additional rationale for the determination of impacts described in the PEIS for orbital debris. For the purposes of the BMDS PEIS "targets of opportunity" are launches or tests conducted for other programs that can be used as part of a passive test of the BMDS. For example, the launch of a National Aeronautics and Space Administration (NASA) launch vehicle may be observed by BMDS sensors to test equipment. In this example scenario, the NASA launch vehicle would be a "target of opportunity." Therefore, targets of opportunity do not create space debris as part of BMDS testing activities.
BMDS	PHO0011-3	Furthermore, while the PEIS considers testing the BMDS on targets of opportunity, no mention is of the space debris resulting from U.S. targets of opportunity or other nations' targets of opportunity.	See previous response.
BMDS	E0427-15 and E0439-15	14) The environmental consequences of many rocket launches needed to deploy and maintain space- based interceptors has not been adequately considered, nor has the environmental consequences of their fuel. Will space-based satellites/interceptors use nuclear power sources? Will any BMDS interceptors ever use nuclear warheads? While nuclear tipped-interceptors are not mentioned in the PEIS, per se. In Section 2.2.1.1 the PEIS does mention	As stated in the BMDS PEIS, the launch vehicles used to insert space-based platforms into the proper orbit would likely be existing launch vehicles; therefore, the impacts of these launches would be as described for Support Assets. The PEIS states that interceptors may use non-nuclear lethality enhancers to increase the probability of a

Exhibit K-2. Responses to Comments – BMDS and Components

Issue Topic	Comment Number	Excerpt Text	Response
		the possibly of destroying a missile by using interceptors with directed blast fragmentation kill vehicles. However the PEIS, fails to reveal the nature of the blast fragmentation device, which is needed for evaluation of its environmental effects. Instead the MDA PEIS states that "the interceptors will be discussed and analyzed for environmental impacts at the booster and kill vehicle level. This will allow the MDA the flexibility to configure new interceptors based on boosters and kill vehicles analyzed in this document to address new or emerging threats." This does not allow a satisfactory evaluation of the hazards of the BMDS components. What blast fragmentation devices will be used? The PEIS needs to include the details of chemical and toxicant use and exposure.	successful intercept. The PEIS also states that because the BMDS does not include nuclear weapons, the requirements of DoD 4160.21-M-1, Appendix 4, Category XVI, Nuclear Weapons and Test Equipment do not apply. The PEIS describes the proposed BMDS including interceptors, in sufficient detail to facilitate a programmatic analysis of the potential impacts of implementing the BMDS.
BMDS	E0427-16 and E0439-16	15) Radioactive and/or biological weapons fallout from intercepted missiles has not been considered in the PEIS. If a kinetic hit to kill interceptor knocks out an ICBM in the mid phase or terminal phase, the nuclear warhead or its fragments are going to produce a tremendous amount of radioactive contamination where ever they land. Such radioactive fallout will clearly have major, highly deleterious effects on adults, children, and especially on developing embryos, and fetuses. While such an interception is very likely to be highly preferable to damage resulting from an air or ground burst over a city, the resulting radioactive contamination needs to be considered. The effects of war are normally excluded from analysis by the National Environmental Policy Act (NEPA). However, the proposed BMDS action is very likely to provoke a worldwide WMD arms race, and force	There would be no radioactive or biological material from missile intercepts during system integration testing of the proposed BMDS. Such material would not be used in any targets used for intercept and would only be expected in enemy missiles which would be launched to attack the U.S. Any intercepts resulting from such an act of war upon the U.S. would not need to be considered in this PEIS, because as the commenter correctly points out the effects of war are normally excluded from analysis under NEPA.

Exhibit K-2. Responses to Comments – BMDS and Components

Issue Topic	Comment Number	Excerpt Text	Response
		other nations to prepare to launch a massive retaliation against the US should war ensue. Thus, these effects need to be considered relative to a real no action alternative. Since the proposed BMDS is very likely to cause a massive arms race, the environmental consequences of a resulting War involving nuclear or other WMD should not be ignored. The PEIS needs to consider the environmental effects of fallout from intercepted WMD as well as the effects of WMD the BMDS fails to intercept. Thus PEIS needs to consider these hazardous waste and materials issues. Appropriate references include "The Effects of Nuclear Weapons, Compiled and Edited by Samuel Glasstone and Philip Dolan, third Ed. DOD, DOE. 1977.	
BMDS	E0427-18 and E0439-18	17) Also note that the technology and environmental effects of "advanced systems" remain to be defined. How can the environment effects of an undefined "advanced system" be evaluated in this PEIS? A full environmental analysis is needed for each component of the PEIS to be added. If any component of the BMDS will ever use nuclear warheads in any interceptors the MDA needs to thoroughly consider the environmental effects, as discussed above.	Appendix F of the BMDS PEIS provides a brief overview of proposed Advanced Systems concepts. Because these ideas and concepts are still emerging, the BMDS PEIS provides a top level review of these programs, as the technology for these systems becomes more advanced, additional tiered site- and component-specific analysis will be developed as required. In addition, see response to comment DC_E0439 (DC_E0427)-15.
BMDS	E0427-19 and E0439-19	18) Will any MDA interceptors or Lasers use anti-matter weapons? A US Air Force anti-mater weapons research programs has recently been described in the SF Chronicle http://sfgate.com/cgi-in/article.cgi?file=/c/a/2004/10/04/MNGM393GPKl.DTL. IF the BMDS will use antimatter weapons or energy sources, the environmental effects including the health and safety risks, and chemical exposure risks need to be described in detail.	The BMDS envisioned by the MDA would include the use of weapons as described in the BMDS PEIS. The BMDS would not include the use of "anti-matter" weapons.

Exhibit K-2. Responses to Comments – BMDS and Components

Issue Topic	Comment Number	Excerpt Text	Response
BMDS	E0427-21 and E0439-21	The following points are points that need to be considered in the no action alternative. 20) The PEIS needs to consider whether the BMDS will result in Proliferation of Weapons of Mass Destruction (WMD) and an arms race in space. The response of other nations to the BMDS has not been considered. Specifically, the BMDS is coupled to other offensive weapons programs and will force other nations to proliferate and/or smuggle WMD so that they can re-establish deterrence. Relatively inexpensive countermeasures to BMD will likely thwart the goals of BMD. Such proliferation coupled with increased international tension will decrease rather than increase our security and lock us in to an expensive and destabilizing amis race and will have devastating long-term environmental consequences.	The Department of Energy (DOE) review was critical because it involved the use of nuclear power, which is not an issue associated with the proposed BMDS. The nature of the proposed system is one that is comprised of existing and new/proposed systems/technologies that are becoming mature and providing new capabilities to destroy a threat missile before it could carry out its mission. It is not reasonable to assume that all activities would stop on individual systems dealing with security and defensive issues in the absence of an integrated system. Nor is it reasonable to assume that the testing of an integrated BMDS would lead to nuclear proliferation any more than other general U.S. international policies and positions.
BMDS	F0005-11	For example, the PEIS projects 515 BMDS launches over the next decade. The sheer volume of this many launches dwarfs the number of projected government and commercial launches over the same period, and the volume of solid rocket propellant involved will generate large quantities of hydrogen chloride, which reacts in the atmosphere to create acid rain.	The PEIS considers the conservative scenario of conducting up to 515 BMDS-related launches over the ten-year period. This would include launch of interceptors and targets. Appendix I of the PEIS provides the background information used to determine the potential cumulative impacts from BMDS launches. This appendix provides the total amount of hydrogen chloride expected to be released from up to 515 BMDS launches. The PEIS finds that the emission loads of chlorine (from hydrogen chloride and free chlorine) from both BMDS and other launches worldwide would account for only 0.5 percent of the industrial chlorine load from the U.S. alone over the same 10 year period. The cumulative impacts analyses of the BMDS implementation alternatives are provided in Sections 4.1.4 and 4.2.3 of the PEIS.

Exhibit K-2. Responses to Comments – BMDS and Components

Issue Topic	Comment Number	Excerpt Text	Response
BMDS	PHO0044-4	Probably the most serious problem is that this document is largely irrelevant. As the summary in Section 1.2 indicates, environmental analyses have been done for most of the components already. Notable exceptions are sea-based midcourse defense and space weapons, which to my knowledge have not been analyzed.	The PEIS examines the potential environmental impacts of MDA's concept for developing and implementing an integrated BMDS, based on Congressional and Presidential direction. The PEIS provides the framework for analyzing the development, testing, deployment, and planning for decommissioning of the BMDS. As Section 4.2.1 of the PEIS states, the potential impacts associated with the use of space-based interceptors are considered in the PEIS and additional environmental analyses would be conducted as needed when the technologies intended to be used become more defined and robust. Aegis BMD operations are addressed in the PEIS to the same extent as other ballistic missile defense programs. As detailed in the PEIS the individual program elements while developed individually historically are now undergoing integration testing to provide a layered BMDS capable of destroying all ranges of threat missiles in all flight phases. Specific test locations and activities are not analyzed in this PEIS; however, MDA routinely considers all test activities, including those involving Aegis BMD as player or watcher, to determine and prepare the requisite level of NEPA analysis. MDA will continue to consider the environmental impacts of its testing programs tiering from the PEIS, as appropriate.
BMDS	PHO0044-5	R&D and testing of most of the components is well underway and decisions have mostly been made about these systems, including even decisions about the initial	See previous response.

Exhibit K-2. Responses to Comments – BMDS and Components

Issue Topic	Comment Number	Excerpt Text	Response
		deployment of the ground-based midcourse defense and the sea-based midcourse defense.	
BMDS	PHW0001-2	The system being deployed has no demonstrated capability against a real attack and is missing most of its major elements, including (l) the X-Band radar; (2) the satellite constellations SBIRS-High and SBIRS-low (the-latter now called STSS), and (3) adequate discrimination capability by its exo-atmospheric kill vehicle interceptor, the EKV, which is also missing. The inescapable conclusion is that the Administration is deploying a system that doesn't work and hasn't been adequately tested. Moreover, it will not have the capability even theoretically to protect much of the United States.	The deployment of an initial defensive capability referred to as Initial Defensive Operations (IDO) or Initial Defensive Operations Capability (IDOC) has been considered in previous NEPA documents including the GMD IDOC at Vandenberg Air Force Base (AFB) EA and the National Missile Defense (NMD) Deployment EIS. Subsequent decisions regarding deployment of an initial defensive capability have been made based on these analyses as documented in the GMD IDOC at Vandenberg AFB Finding of No Significant Impact and the GMD IDOC at Ft. Greely ROD (based on the NMD Deployment EIS).
BMDS	PHW0002-2	Alternative 2, which includes the usage of space-based interceptors (SBIs), is questionable for many reasons. It looks at the effect of using space-based interceptors in lieu of terrestrial-based ones; however, the BMDS that is repeatedly envisioned by MDA and Pentagon officials is one where targets would be engaged at all stages in their flight, from all types of launch platforms. To look only at the usage of an SBI is to willfully ignore the concept of operations that has been used to justify this massive defense system. The American Physical Society, in its boost-phase intercept study released in July 2003, estimated that a constellation of at least 1000 SBIs would be required to provide a minimal defense against liquid-fuelled ICBMs. Granted, testing would be of a much lesser nature than a complete constellation, but at some point presumably the system would be tested at some	In Alternative 2 the PEIS considers the use of weapons from land-, sea-, air-, and space-based platforms. Because the analysis of impacts of using weapons from land-, sea-, and air-based platforms was considered in Alternative 1, the PEIS focuses on the impacts of using weapons from space-based platforms in the discussion of Alternative 2. These impacts would be in addition to those impacts for Alternative 1, as was stated in the first paragraph of Section 4.2 of the PEIS. Section 4.2.2 considers the potential environmental impacts from System Integration Tests using land-, sea-, air-, and space-based platforms for weapons, sensors, C2BMC, and support assets. The PEIS considers the impacts of the proposed BMDS as currently envisioned over a period of ten years. Other actions that are outside this evaluation period are outside of the scope of this PEIS and would need to be considered in future analyses.

Exhibit K-2. Responses to Comments – BMDS and Components

Issue Topic	Comment Number	Excerpt Text	Response
		fraction of its full strength. This draft PEIS does not take into consideration that possibility.	
BMDS	F0004-3	2 You have said in the past year that there are NO longer plans to install Missile Silos on Kodiak. Keep that Plan. No Silos...Period. You must keep your word true to us citizens. After all its OUR Home + Our Program too.	The PEIS does not address specific locations for BMDS assets for the implementation alternatives; it provides examples of test locations so that resources can be examined for the potentially affected environment. At this time, the MDA has no plans to construct/operate silos at KLC.
BMDS	PHO0023-4	The same with the Airborne Laser. There is a very good probability that an Airborne Laser would never work in shooting down a missile in the boost phase and all tests indicate that. But it could be highly effective in a directed energy targeting on Earth for terrestrial targets. And you should be honest about what that weapon might also be used for. It would be helpful to actually not mask the true purposes of some of these weapons.	The ABL is designed to intercept threat missiles in the boost phase of flight. The ABL would be deployed to and operate in areas where boost-phase intercepts could be attempted. Its effectiveness is undergoing thorough testing as an integral component of the BMDS boost phase defense. The MDA has no plans to use the ABL for terrestrial targets.
BMDS	E0162-3	1) The PEIS should give quantitative information on the reliabilities of the boosters to be used to launch targets for BMDS tests. I noted in my scoping comment (See first comment on page B-15 of the draft PEIS.) that I had asked for this information in my comments on the 1994 BMD draft PEIS and that the response was inadequate for any meaningful assessment of the risks from launch failures. This information is especially important to include in the PEIS because the same target boosters are used in various test programs and because the information has not been included in previous environmental analyses. I noted in my comments on the 2003 GMD ETR draft EIS that an analysis of Minuteman test launches found a rate of severe failures of 15% and that the Strategic Target System has had one serious failure (9 Nov. 2001 launch from Kodiak)	Booster reliability is considered for individual tests. The range or facility safety personnel at the locations of the testing calculate the impact zones for intercept debris as well as impact areas where a non-nominal or errant target or interceptor would impact. These calculations consider the impact areas including the effects of the use of a flight or thrust termination system or other safety measures. In addition, strict range/facility safety procedures required by each range/facility would be adhered to. The MDA uses many different boosters in its testing program and the risk associated with any specific booster would be assessed and addressed by range or facility safety personnel prior to a test.

Exhibit K-2. Responses to Comments – BMDS and Components

Issue Topic	Comment Number	Excerpt Text	Response
		in five launches. Including my scoping comment in exhibit B-9 as a health and safety issue seems to imply that this aspect should be analyzed in the PEIS. At the 26 Oct. public meeting in Honolulu, I was assured that including booster reliability information would be considered.	
BMDS	F0005-15	1) In order to evaluate the risks from launch failures, the PEIS should give qualitative information on the reliabilities of the boosters to be used to launch targets for BMDS tests.	See previous response.
BMDS	E0162-6	4) Page D-15 of the PEIS contains misleading information about previous NEPA analyses related to Aegis BMD. It cites the 1998 PMRF Enhanced Capability EIS as a supporting NEPA analysis. In fact, this EIS explicitly excluded the Navy Theater-Wide System (now called Aegis BMD) from evaluation. No subsequent environmental analysis has been done even though Aegis-LEAP tests have been done near PMRF. The PEIS should indicate when environmental analyses of this system will be done. Press reports have indicated that 20 sea-based midcourse interceptors are scheduled for deployment in 2005. The PEIS states on page D-19 that three Aegis BMD cruisers and 15 Aegis BMD destroyers would be available for deployment at the end of Block 2004.	As noted in the 1998 Pacific Missile Range Facility (PMRF) Enhanced Capability EIS, the Theater-Wide system would be designed to engage missiles at long-range and high altitude (outside the atmosphere) and to protect a very large area (theater). This capability is especially important if the attacking missile is carrying a nuclear, chemical, or biological warhead. The Theater-Wide program would provide vital political and military assets, supporting infrastructures, population centers, and entire geographic regions with timely and extensive protection against medium/long range Theater Ballistic Missiles. Operating in international waters, forward deployed ships equipped with the Navy Theater-Wide Theater Ballistic Millise Defense system would have the capability to engage Theater Ballistic Missiles early in their ballistic missile trajectory. Multiple ships operating in mutual support would be capable of providing the layered defense and overlapping coverage that lead to improved levels of protection. It was determined that the Theater-Wide program was not sufficiently developed to be evaluated in the 1998 document. However, Aegis

Exhibit K-2. Responses to Comments – BMDS and Components

Issue Topic	Comment Number	Excerpt Text	Response
			Lightweight Exoatmospheric Projectile intercept tests are designed to assess interceptor missile operations outside of the atmosphere. These tests were analyzed in the 1998 EIS.
BMDS	F0005-18	(4) The PEIS should indicate when an environmental analysis of the Aegis BMD system will be done. The earlier EIS relied upon at page D-15 contains misleading information.	See previous response.
BMDS	E0162-12	10) The brief history of U.S. missile defense activities in section 1.2 excludes any mention of critical technical analyses of components and testing of them. For example, the 1998 report of the Pentagon panel headed by Gen. Welch characterized the inadequate preparation for flight tests as a "rush to failure." Two GAO reports in 2003 (GAO-03-441 and GAO-03-600 available at www.gao.gov) questioned the adequacy of testing and readiness for NMD deployment. The May 2004 report Technical Realities (available at www.ucsusa.org/global_security/missile_defense/index.cfm<http://www.ucsusa.org/global_security/missile_defense/index.cfm>) by the Union of Concerned Scientists provided a critical analysis of the NMD system being deployed. It is noted on page 1-7 that Pres. Bush's 17 Dec. 2002 decision to deploy an initial defense capability followed "continued test bed development and successful flight test activities." It should be added that this decision followed by six days a test failure and that the test record so far is five intercepts in eight attempts.	These comments have been noted for the record. Section 1.2 of the BMDS PEIS is intended to provide the reader with a brief history of U.S. missile defense activities. The PEIS is a programmatic level analysis of potential environmental impacts associated with the implementation alternatives identified for the proposed BMDS. It does not address DoD threat assessment policy-making issues or the technological feasibility of missile defense system design. Appendix D of the PEIS was intended to provide the reader with a very brief historical perspective on the past development including relevant NEPA analyses, of various DoD programs whose components are being considered for integration into the proposed BMDS. The specific numbers of intercepts or failures of previous Aegis LEAP tests are not relevant to the consideration of environmental impacts from the system integration testing of the proposed integrated BMDS. As specific Aegis BMD components take part in specific system integration tests, analysis of environmental impacts will be analyzed in NEPA documents appropriately tiered from this PEIS.

Exhibit K-2. Responses to Comments – BMDS and Components

Issue Topic	Comment Number	Excerpt Text	Response
BMDS	E0162-13	11) The brief history of the Lightweight Exoatmospheric Projectile (LEAP) program on page D-17 states that tests in the early 1990's showed that LEAP "could be integrated into a sea-based tactical missile for ballistic missile defense." In fact there were no successful intercepts in five attempts in these tests. Two successful Aegis LEAP intercept tests in 2002 are described but there is no mention of the intercept failure on 18 June 2003. The Aegis LEAP test record so far is four intercepts in five attempts.	See previous response.
BMDS	E0162-14	12) It is stated on page D-40 that there were eleven THAAD flight tests in the 1990s and that, "Upon successful intercept, the THAAD program began planning to validate the performance capability and overall effectiveness of the THAAD element, flights tests, and intercepts of target missile launches over more realistic distances..." Of the eight intercept attempts in the 1990's tests, there were only two hits.	See previous response.
BMDS	E0319-11	The PEIS should include all proposed laser test sites including the BOA, and, what experiments will take place at each site, and the total amount of acreage needed as a safety zone. For example, will the Airborne Laser 'test fire' at targets or interceptors launched from Vandenberg AFB, Kwajalein, Kodiak Island, Fort Greeley, or Poker Flats Rocket Range, Alaska?	The PEIS does not address specific locations for BMDS assets for the implementation alternatives; it provides examples of test locations so that resources can be examined for the potentially affected environment. If future plans identify specific locations that are required to support laser activation tests, they would be considered in subsequent tiered NEPA analyses.
BMDS	E0319-14	Draft PEIS Volume 2, pages D-25, D-26 (Exhibit D-6) states Ground-Based 'Interceptors' will be launched from the Kodiak Launch Complex (KLC), Alaska. In the Fall of 2003, a press release by the MDA stated only target missiles, not interceptors would be launched from the	The GMD ETR EIS did analyze the environmental impacts of launching interceptors from KLC. As the commenter correctly states, the MDA announced in a ROD that there were currently no plans to launch interceptors from KLC. This is still the case. The information presented in Appendix D has been corrected

Exhibit K-2. Responses to Comments – BMDS and Components

Issue Topic	Comment Number	Excerpt Text	Response
		KLC. No previously released EAs or EISs have included plans for launching interceptors from Kodiak Island.	in the Final PEIS to reflect that there are currently no plans to launch interceptors from the KLC.
BMDS	E0395-11	The PEIS states that space-based interceptors could be placed in geosynchronous orbit: 35,786 kilometers above the Earth's surface. To actually get a weapon from geosynchronous orbit to low-Earth orbit or even a lower trajectory of a missile within 20 minutes or half hour and do so accurately is physically impossible. Therefore the PEIS has mischaracterized this space weapon. Simply, any weapon placed in geosynchronous orbit could not be an anti-missile weapon. However such a deployment could be an anti-satellite weapon, an ASAT. The agency should then go through the process of trying the field this ASAT weapon on its own merits.	The BMDS PEIS states that space-based platforms for sensors or C2BMC could be placed into Geosynchronous Earth Orbit (GEO); however, there is no mention of placing space-based platforms for weapons into GEO. If future plans were to identify the need for the use of space-based platforms for weapons in GEO, they would be considered in subsequent tiered NEPA analyses, as appropriate.
BMDS	PHO0023-3	The other thing I want to bring up is in regards to in the PEIS there is some statements in the effect that some of the space-based interceptors would be placed in geosynchronous orbit, which I believe is some 24,000 kilometers from Earth. To actually get a weapon from 24,000 kilometers out to what would be a low-Earth orbit or even a lower trajectory of a missile within 20 minutes or half hour and do so accurately and to hit the missile is fantasy. And therefore I think the PEIS mischaracterizes any weapon that would be placed in geosynchronous orbit as being an anti-missile weapon. It should simply not be listed as a possibility. That would be -- well, you would be deploying an ASAT -- an anti-satellite weapon. And you should go through the process of actually fielding that before the public and have -- and take your hits for that if, indeed, you're doing that.	See previous response.

Exhibit K-2. Responses to Comments – BMDS and Components

Issue Topic	Comment Number	Excerpt Text	Response
BMDS	E0395-12	With respect to the Airborne Laser, the PEIS says that, "the ABL is currently the only proposed BMDS element with a weapon using an air platform." This is not correct. The PEIS should also address another proposed BMDS element using air platforms, namely, interceptors fired from aircraft.	At this time there are no plans to use any weapons other than the ABL from air-based platforms to support the BMDS. If future plans were to identify the need to use other weapons from air-based platforms, they would be considered in subsequent tiered NEPA analyses, as appropriate.
BMDS	PHO0026-1	The Airborne Laser is currently the only -- emphasize only -- proposed BMDS element with a weapon using an air platform, closed quotes. However, the PEIS does not discuss another proposed BMDS element that would use air platforms; namely, interceptors fired from aircraft.	See previous response.
BMDS	E0395-16	A third interceptor site is mentioned in the PEIS but it's location is not stated or described. More importantly, the environmental impact of BMDS operations at that third site are not addressed either. MDA officials have said that this third site could hold up to 20 ground-based interceptors and be bigger than the site at Fort Greely, Alaska. The environmental impacts of such as large operation should be addressed.	The PEIS does not address specific locations for BMDS assets for the implementation alternatives considered in the BMDS PEIS; rather it provides location types so that resources can be examined for potentially affected environments. As the BMDS is a defense system undergoing constant scrutiny for improvement, there could be additional locations for various components being considered at stages too preliminary for NEPA analysis. As additional locations or facilities are identified as necessary to support the BMDS, they would be considered in subsequent NEPA analyses tiered from the PEIS, as appropriate.
BMDS	E0401-1	I would like to raise the issue of the 3rd ground-based interceptor site, something which I believe has been completely overlooked in the draft Ballistic Missile Defense System Programmatic Environmental Impact Statement. There is no hard and fast information in this document which indicates where the 3rd interceptor site may be located. However, news stories this fall claim that the United States has been discussing with the United	See previous response.

Exhibit K-2. Responses to Comments – BMDS and Components

Issue Topic	Comment Number	Excerpt Text	Response
		Kingdom the possibility of basing our interceptors on their territory. Alternatively, there are reports that Poland may be the host of the third site. Be that as it may, the draft PEIS gives no indication of where the third site will be, nor of the extent of its size. Presumably, if this document is to lay the groundwork for the missile defense network in its entirety, at least several of these alternatives would have to be examined.	
BMDS	PHO0011-4	The environmental consequences of mini rocket launches needed to deploy and maintain space-based interceptors has not been adequately considered, nor has the environmental consequences of the fuel. They talk about having all of the -- these -- in other words, in Option 2, they have many different interceptors in space that would have a reduced environmental consequence. But there's no consideration you have to launch all of those missiles in the place to get there.	As stated in the BMDS PEIS (Section 2.2.4 Support Assets), the launch vehicles used to insert space-based platforms into the proper orbit would likely be existing launch vehicles; and therefore, the impacts of launches to deploy and maintain BMDS assets in space would be as described for Support Assets.
BMDS	PHO0037-4	Another concern is that it didn't really look at the many rocket launches that are needed to test and deploy and maintain the space interceptors.	See previous response.
Decommis-sioning	M0268-2	When it comes time for decommissioning the military often finds it does not have the technology, or the funds required, to clean up damaged sites. This has certainly been true of other complex systems, like those involving chemical and nuclear weapons. In those cases there is still uncertainty about how to safely destroy or store decommissioned weapons and the associated toxic wastes. MDA needs to address these questions satisfactorily in advance. We suspect they are not addressed because costs involved would be prohibitive and in some cases the technology for disposal does not exist.	Section 4, Environmental Consequences, Decommissioning Phase Activities, of the PEIS states that environmental impacts associated with decommissioning of specific components would be more appropriately addressed in subsequent tiered environmental analyses. However, this section provides a roadmap for considering the impacts of decommissioning for each component. Future tiered analyses would consider specific environmental impacts related to decommissioning individual components as appropriate.

Exhibit K-2. Responses to Comments – BMDS and Components

Issue Topic	Comment Number	Excerpt Text	Response
Radar	PHO0038-2	I remember from last time, part of about the radar, somebody from Valdez was worried about that it was going to set off airbags in cars, set off fire extinguishers, some kind of weird effects of the radar, but I didn't see any mention of that in there and I didn't get a chance to read the whole thing.	Potential health and safety impacts of radars are outlined in Section 4.1.1.3 of the document. The MDA has found no indication that effects of EMR would include setting off vehicle airbags or initiating fire extinguishers.
Radar	E0402-2	None of the X-band radars that are central to the system are built hence we are exposing ourselves and the world with a system that has no hope of working.	As noted in Section 2.2.2, the BMDS would consist of three different types of sensors: weapon/element sensors, BMDS mission sensors, and test range telemetry sensors. The BMDS mission sensors would provide information for missile warning, early interceptor commit, in-flight target updates, and target object maps. As part of a layered and integrated system, numerous sensors would be used to direct and track threat missiles; direct interceptors or other defenses; and assess whether a threat missile has been destroyed.
Radar	M0161-1	In addition, the Administration's missile defense system lacks a key component: the X-band radar intended to track incoming warheads and help guide the interceptors to their targets.	See previous response.
Radar	M7806-1	It is also my understanding that the deployment is being made without the radar system because it is faulty. How, might I ask will a missile be guided?	See previous response.
Sensors	E0142-1	Very briefly, it is my perception that the state of the art in automatic image analysis is such that reliable object recognition is possible only in well-controlled environments wherein the quiescent illumination, the clutter, and preferably the orientation of the target object are under control. These environmental constraints obviously cannot be imposed on a ballistic missile defense system, and therefore one should be very skeptical of	Sensors would be tested to evaluate performance in detecting and tracking threat ballistic missiles. Tests would use targets of opportunity as well as BMDS targets. Performance would be evaluated by comparing observed and predicted performance of the test sensor's ability to detect the target, accurately measure and track the target, and discriminate the reentry vehicle from countermeasures. Generally, components would be

Exhibit K-2. Responses to Comments – BMDS and Components

Issue Topic	Comment Number	Excerpt Text	Response
		claims that enemy missiles can be reliably identified. To the extent that the proposed system depends on automatic detection of enemy missiles, it is very unlikely that it will be reliable, given the present state of the art.	deployed after sufficient testing to demonstrate that they are capable of operating successfully within an integrated BMDS.
Weapons	E0387-4	Missile Defence plans extend to the possible deployment of space-based weaponry and space-based weapons systems. It is crucial that the PEIS consider seriously the likely impact of space weapons deployment. The use of space weapons, for whatever reason, to attack or destroy objects outside of the atmosphere would produce space debris, changing the near Earth environment and would become a serious hazard to future space missions, even possibly preventing them from leaving Earth. At the speeds required to escape the Earth's gravitational pull, the impact of just a tiny object on a space rocket could be disastrous. Space-based conflict of any sort could add to this problem enormously and it is an issue that deserves serious attention.	The impacts from the use of space-based weapons are considered in Sections 4.2.1 and 4.2.2. This analysis includes consideration of orbital debris that would be produced as a result of placing and testing weapons in space. MDA has added Technical Appendix L to the Final PEIS to discuss orbital debris issues more fully.
Deployment	E0395-8	In the statement read by Mr. Marty Duke at the Public Hearing held in Sacramento on October 19, 2004, Mr. Duke said that if testing failed to show that the system worked, the system would not go forward. However, as you know, the system is already being deployed even though it has no demonstrated capability to work under realistic conditions. Accordingly, the environmental process described in this PEIS is not believable since the statement made by Mr. Duke on October 19 has already been nullified by the Missile Defense Agency.	The MDA has not made a decision on how to implement the BMDS. The commenter is referring to a decision made by President Bush explained in Section 1.2 of the PEIS to implement an initial defensive capability to protect the U.S. Homeland. This decision in itself does not constitute a decision on how to configure or deploy the BMDS. The statements made at the public hearing which are available on the MDA PEIS web site are accurate and constitute the MDA's current acquisition strategy which allows for reviews of a proposed component's operational feasibility during all life cycle phases of the component's development.

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
Airspace	E0402-7	4) The risk of accidental missile launching to civilian or military aircraft is a real concern. The window of opportunity for successful launch is too narrow given its unproven track record, that the target identification is inadequate. This will result in incredible toxins being released as aircraft contain fuel, sometimes depleted uranium ballast, among other cargos not to mention the deaths of innocent victims.	BMDS testing activity would be limited to areas of restricted range and airspace. Before testing is conducted, range areas would be cleared and NOTAMs would be issued to the public. Airspace designations would be such that even in the event of an anomaly, debris would not pose a danger to health and safety. The PEIS does not consider the impacts to airspace during an actual threat missile launch and subsequent use of the system.
Airspace	PHO0011-2	While the BMDS states that warning will be provided to enable time to clear the air space, it's highly doubtful that such time would be allowed in such an emergency.	See previous response.
Biological Resources	E0030-2	10) The environmental effect of the X-band radar upon people and birds have not been thoroughly studied.	The environmental impacts of radar, including radar operating within the X-band, on birds is considered in Section 4.1.1.1 of the PEIS. In addition, the PEIS incorporates by reference previous NEPA studies in which the potential impacts of radar activation on biological resources are considered (see Appendix N of the PEIS).
Biological Resources	F0004-5	4 Dropping Rocket booster stages anywhere along the east side (or interior) of Kodiak Island is totally unacceptable! It is all critical habitat area for the endangered Steller Sea Lions. There are numerous haul-outs + rookeries all along the Coast of the Kodiak Archipelago. We commercial fisherman have severely shut down from fishing near any of these places So...you can't disturb them either! If you kill any off we get the blame, and we will be shut completely down from fishing! Please consider our fate to make a living ok.	The site-specific detail of this comment cannot be appropriately considered in this type of programmatic environmental analysis. However, additional text has been added to the Final PEIS to explain that meetings with the USFWS and National Oceanic and Atmospheric Administration (NOAA) National Marine Fisheries Service occurred. Additional information about possible impacts to biological resources from launch debris including booster stages impacting land and water are considered in Section 4.1.1.2 of the PEIS.

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
Biological Resources	PHO0010-1	But the truth is over the decade life of the program, the global level of perchlorates may rise. Amphibians skin needs to be moist. They're very sensitive to all industrial chemicals. Seventy percent of the species are in decline right now, even in habitats that aren't disturbed. Why would we care about them? The mosquitos are coming out. We don't have hard figures. We don't have real analysis. We're told this is a half a percent. What they're disguising there is most of the chemicals are residual from former manufacturing processes. And even so, the largest contributor -- as a scientist, I'm simply telling you, the largest contributor actually is the manufacturing, testing, open detonation of old rocket motors and the whole thing.	Historically, the manufacturing and disposal of solid rocket propellant that contains ammonium perchlorate as an oxidizer has led to perchlorate contamination. There is no evidence to suggest that burning solid propellant in a solid rocket motor (SRM) leads to emissions of perchlorate to the atmosphere. Perchlorate could be released into the environment in the form of uncombusted solid rocket propellant from a non-nominal launch or other accident causing release of solid propellant to land or water. These have been considered in the PEIS. Additional information on perchlorate has been added to the PEIS text as well as a technical appendix (Appendix M) on perchlorate. This appendix considers the uses, sources, and disposal of perchlorate as well as the human health and ecological risk of exposure to perchlorate.
Cultural Resources	PHO0051-8	Hawaiian burials and sacred sites are desecrated by the missile launches and Star Wars facilities, while cultural practices and subsistence access rights are denied due to base security measures.	The PEIS analyzes the programmatic development, testing, deployment, and planning for decommissioning activities for an integrated BMDS. Specific facilities that would be used to carry out subsequent activities comprising the life cycle phase testing would be analyzed in site-specific documents. These subsequent NEPA analyses could tier from this PEIS, as appropriate.
Cumulative Impacts	E0162-5	3) The PEIS discussion of cumulative impacts in section 4.1.4 and Appendix I has no details about the location, schedule, and specific missiles to be used for the estimated 515 launches from 2004 to 2014. This is important because there are annual limits on the numbers of launches at the Pacific Missile Range Facility (PMRF), Kodiak, and Vandenberg AFB, as noted in the GMD ETR EIS. The GMD ETR EIS estimated 10 launches per year	The PEIS is a programmatic level NEPA analysis that considers implementation alternatives for an integrated BMDS. The PEIS considers the program as a whole to allow tiering of subsequent site-specific analyses from the PEIS and as such does not address specific sites or specific activities at those sites. Launches occurring from site-specific locations would not exceed annual launch limits established by the range.

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		so the PEIS needs to give some details about the additional 415 launches. Some information about future launches for tests of some BMDS components is provided in Appendix D. However, there are no estimates for Aegis BMD tests and only vague estimates for GMD tests. For example, it is stated on page D-25 that, "GMD test plans include a number of missile-launches (interceptors and/or targets) from each launch facility per year." The PEIS should also include impacts of test launches of offensive missiles. For example, tests of the Trident D5 are reported to be planned near PMRF in 2005.	The number of launches considered in the PEIS includes not only the launch of ground-based interceptors (GBIs), but also the launch of targets and other missiles used in testing individual components of the BMDS and system integration flight testing. As stated in Section 2.1, the BMDS is designed to negate threat ballistic missiles and thus is comprised of multiple defensive weapons. The BMDS is not designed to be an offensive system. Test assets, such as targets, that would be used to test BMDS components have been included in the 515 projected launches that were analyzed to determine the cumulative impacts of BMDS launches.
Cumulative Impacts	E0319-20	Page 4-112, Section 4.1.4-Cumulative Impacts, does not give any useful or detailed information regarding the 515 projected BMDS launches during 2004-2014. The PEIS needs to include a breakdown of the 515 proposed launches and where each launch will take place (ground-based, sea-based, and space-based test locations). Where did the MDA come up with the 'magic' number of 515? A total of only 10 launches per year have been proposed from the KLC in previous EA documents (Air Force, Army). The MDA needs to validate and justify the need for 515 launches, considering the fact that 'Emissions from activities for the proposed BMDS include carbon monoxide, sulfur oxides, nitrogen oxides, volatile organic compounds, hazardous air pollutants, and particulate matter'. 'Most sites where activities for the proposed BMDS may occur would be classified as a major emissions source' (BMDS Draft PEIS Volume 2, pages H-18- H-19-Existing Emission Sources)	The PEIS is a programmatic level NEPA analysis that considers implementation alternatives for an integrated BMDS and as such does not address specific sites or specific activities at those sites, but rather considers the program as a whole to allow tiering of subsequent site-specific analyses from the PEIS. As the cumulative consideration of launches is global, the specific launch sites are in fact not needed to consider the cumulative impacts of these launches on global warming or ozone depletion. Launches occurring from site-specific locations would be analyzed as appropriate to ensure that either individually or cumulatively they would not exceed local emissions thresholds or limitations in specific areas. Appendix I notes that as indicated in Ross, 1998 although ozone loss occurs in the plume wakes of the largest solid propellant boosters, the amount and

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
			duration of the loss appears to be temporary and limited. In addition, the cumulative impact from launch emissions has been shown to be insignificant when compared to other sources of greenhouse gases and ozone-depleting substances. Impacts from launches occurring from sites in the Arctic Tundra or the Sub-Arctic Taiga Biomes would be addressed in subsequent site-specific analyses tiered from the PEIS, as appropriate.
Cumulative Impacts	F0005-17	(3) The PEIS discussion of cumulative impacts in Sec. 4.1.4 and Appendix 1 contains no details about the location, schedule, and specific missiles to be used for the estimated 515 launches from 2004 to 2014. They are essential.	See previous response.
Cumulative Impacts	E0319-21	The MDA's own admission in the Draft PEIS confirms the fact that: "Launches can contribute to cumulative impacts including ozone completion, global warming, and orbital debris, which could affect global warming and depletion of the stratospheric ozone layer (Volume 2, page I-2-Cumulative Impacts). The MDA must discontinue all future BMDS test plans which will contribute to further global warming or contamination in the affected Biomes listed in the PEIS; especially the Arctic Tundra Biome and the Sub-Arctic Taiga Biome-which includes areas of the Aleutian Chain where various radars or sensors are activated or will be activated as part of the proposed BMDS (e.g. Adak Island where the Sea-Based X-Band Radar will be home-ported, Shemya Island where the COBRA DANE is located, and the BOA in the Gulf of Alaska).	It was shown in Ross, 1998 (as referenced in Appendix I of this PEIS) that although ozone loss occurs in the plume wakes of large solid propellant boosters, the amount and duration of the loss appears to be temporary and limited. In addition, the cumulative impact from launch emissions has been shown to be insignificant when compared to other sources of greenhouse gases and ozone-depleting substances. Impacts from launches occurring from the Arctic Tundra or the Sub-Arctic Taiga Biomes would be addressed in subsequent site-specific analyses, as appropriate.

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
Cumulative Impacts	E0427-20	19) The BMDS PEIS needs to consider direct, indirect and cumulative effects of the proposed project in conjunction with other federal offensive military weapons systems and policies were not addressed, but need to be addressed. The National Environmental Policy Act (NEPA) (http://ceq.eh.doe.gov/nepa/regs/nepa/nepaeqia.htm) and especially the Regulations for Implementing NEPA (http://ceq.eh.doe.gov/nepa/regs/ceq/toc_ceq.htm), state that both the direct and indirect effects of the proposed project as well as the Cumulative impact of the project should be considered. Sec. 1508.7 States that the "Cumulative impact" is the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time. In the context of this global ballistic missile defense system, the cumulative impact of reasonably foreseeable future actions of the US as well as other nations, agencies and persons need to be considered. Yet the reasonable foreseeable actions of other nations and individuals responding to the BMDS by proliferating WMD was not considered by the MDA in this PEIS. As stated in Sec. 1508.8 "Effects" include:(a) Direct effects, which are caused by the action and occur at the same time and place and (b) Indirect effects, which are	BMDS weapons components are considered defensive weapon system components that would be used to destroy threat missiles. The projected BMDS launches used to calculate the cumulative impacts of launch emissions include targets that would be used to test various BMDS components. The PEIS considered all potential environmental effects including cumulative effects of implementing a proposed BMDS from a programmatic standpoint. The argument that the proposed BMDS would lead other nations to proliferation of weapons of mass destruction is the opinion of the commenter; and as such MDA does not consider it a reasonably foreseeable action to be considered in the PEIS. As shown in Appendix I, foreign military launches were included in the cumulative impacts analysis to consider impacts on global warming and ozone depletion.

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		caused by the action and are later in time or farther removed in distance, but are still reasonably foreseeable. Effects and impacts as used in these regulations are synonymous. Effects includes ecological (such as the effects on natural resources and on the components, structures, and functioning of affected ecosystems), aesthetic, historic, cultural, economic, social, or health, whether direct, indirect, or cumulative. Effects may also include those resulting from actions which may have both beneficial and detrimental effects, even if on balance the agency believes that the effect will be beneficial. Thus, by law the MDA also needs to consider the Direct, Indirect and Cumulative impacts on the environment of the proposed BMDS along with other US offensive weapons systems and stated & demonstrated US preemptive first-strike policy.	
Cumulative Impacts	E0429-10	At least by number, the 515 projected BMDS launches over the decade beginning this year dwarfs the 99 other projected government launches and the 77 estimated U.S. commercial launched anticipated over the same time period. The environmental review of such a large system, to be developed over a period of many years and potentially deployed for decades, provides an opportunity to reconsider the technologies that our country uses for launching rockets. The draft Programmatic Environmental Impact Statement ignores that opportunity.	Section 4.1.4 shows that BMDS launches are only three times the amount of non-BMDS U.S. launches instead of five times the amount as indicated by the commenter. While projected BMDS launches may account for more launches than other U.S. launches, the size of the BMDS boosters would be on average much smaller than those used for other U.S. launches. Boosters were classified into ranges based on the size of the propulsion system. As shown in Exhibit I-2 of Appendix I of this PEIS, all of the 515 projected BMDS launches fall within the low propellant weight category. Therefore emission loads to the stratosphere from BMDS projected launches (shown in Exhibit I-6) are less than those for other U.S. launches (shown in Exhibits I-7 and I-8).

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
			The BMDS PEIS considers the use of a wide variety of propellants including three types of boosters, pre-fueled liquid propellant, non-pre-fueled liquid propellant, and solid propellant boosters. The environmental impacts of the use of each of these three types of boosters are presented in Section 4.1.1.2 of the PEIS.
Cumulative Impacts	PHW0004-10	At least by number, the 515 projected BMDS launches over the decade beginning this year dwarfs the 99 other projected government launches and the 77 estimated U.S. commercial launched anticipated over the same time period. The environmental review of such a large system, to be developed over a period of many years and potentially deployed for decades, provides an opportunity to reconsider the technologies that our country uses for launching rockets. The draft Programmatic Environmental Impact Statement ignores that opportunity.	See previous response.
Cumulative Impacts	E0429-13 and PHW0004-13	Once again, the PEIS acknowledges this environmental impact, but it plays it down: "The cumulative impact on stratospheric ozone depletion from launches would be far below and indistinguishable from the effects caused by other natural and man-made causes." (page 4-114). I appreciate the data presented in Appendix I, but the conclusion reached by the authors is implausible.	As indicated in the PEIS on page 4-114, the chlorine emissions from projected BMDS launches during 2004-2014 is a very small fraction (.05%) of the total chlorine emissions from U.S. industrial sources during that same 10-year period. This does not account for emissions of chlorine from natural causes or from sources throughout the industrialized world, only U.S. industrial sources. Therefore, it is completely plausible that the cumulative impact from BMDS launches on stratospheric ozone depletion would be far below and indistinguishable from chlorine emissions from other natural and man-made causes.
Cumulative Impacts	E0429-14 and PHW0004-14	However, the industrial "emissions" are actually the residuals of production and use of chemical which have been phased out, under the Clean Air Act Amendments of	As the commenter states, production and use of ozone depleting substances are being phased out. The production of the most destructive ozone depleting

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		1990 and a series of international protocols. That is, these substances are already in the environment; nothing can be done to put them back in the bottle. Thus, each year stratospheric releases of rocket fuel exhaust become a larger fraction of the problem, as fewer industrial ozone-depleters are manufactured. More important, the fractional contribution of rocket-launches to ozone depletion does not make it desirable. It is as large as all but the largest industrial releasers, before the phase-out took effect, and orders of magnitude larger than the releases from a home refrigerator or a car air conditioning system. Our environmental laws and policies do not excuse pollution simply because there are other, larger sources. That is, if I were a repairer of air conditioning systems, I could not-and should not -release chlorine-containing refrigerants into the atmosphere simply because a Titan or Delta launch vehicle emits much more chlorine.	substances (Class I substances) has already ended and the production (for domestic use) of Class II ozone depleting substances (which are less destructive than Class I substances) is slated to end by 2030. However, it is expected that emissions of Class I compounds will continue, albeit in ever decreasing amounts, for many more years. The emissions of Class II compounds are expected to increase until many years after the phase-out of these substances is complete. ("Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2001," U.S. EPA 430-R-03-004, April 2003). Therefore, it is unlikely that there will be dramatic decreases in the emissions of the ozone depleting substances for many years and thus rocket emissions will continue to comprise an insignificant fraction of these emissions for the next several decades. Because rocket emissions are released directly into the stratosphere at elevated temperatures, they do not behave exactly like emissions of ozone depleting substances released into the troposphere. Studies have found that although rocket exhaust emissions can cause immediate loss of ozone in individual plumes, the emission plumes from these rockets disperse in a way that makes it highly unlikely these ozone losses will impact areas near launch sites, even with launches of the largest solid rockets. In addition, measurements of rocket plumes from vehicles much larger than those proposed for BMDS have shown that "the amount of ozone destruction does not increase without limit" (i.e., the amount of emissions is not necessarily directly proportional to the amount of ozone

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
			depletion). Ozone loss has also been shown to slow about one hour after launch, suggesting that the most ozone-destructive emissions have been deactivated by reactions with various gases in the surrounding air and that the duration of the impact of these emissions is fairly short, especially compared to other ozone depleting substances that persist for many years in the stratosphere. Based on this and other related research, the Air Force and the entire space-launch community are "confident that ozone loss from both individual and collective launches does not constitute a significant environmental hazard." (http://www.aero.org/publications/crosslink/summer2000/01.html)
Cumulative Impacts	E0439-20	19) The BMDS PEIS needs to consider direct, indirect and cumulative effects of the proposed project in conjunction with other federal offensive military weapons systems and policies were not addressed, but need to be addressed. The National Environmental Policy Act (NEPA) (http://ceq.eh.doe.gov/nepa/regs/nepa/nepaeqia.htm) and especially The Regulations for Implementing NEPA (http://ceq.eh.doe.gov/nepa/regs/ceq/toc_ceq.htm), state that both the direct and indirect effects of the proposed project as well as the Cumulative impact of the project should be considered. Sec. 1508.7 States that the "Cumulative impact" is the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions. Cumulative impacts can result from individually	BMDS weapons components are considered defensive weapon system components that would be used to destroy threat missiles. The projected BMDS launches used to calculate the cumulative impacts of launch emissions include targets that would be used to test various BMDS components. The PEIS considered all potential environmental effects including cumulative effects of implementing a proposed BMDS from a programmatic standpoint. The argument that the proposed BMDS would lead other nations to proliferation of weapons of mass destruction is the opinion of the commenter; and as such MDA does not consider it a reasonably foreseeable action to be considered in the PEIS. Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
Cumulative Impacts	PHO0009-1	It's ridiculous that the -- there is 515 launches proposed for Star Wars. That is five times the amount that would be launched under the programs that are non-Star Wars. And you can look this up for yourself. Don't trust me. Check it out. The second thing is the PEIS is based on the Star Wars program as proposed -- and here we have a statement. Okay. This statement was made by General Henry Tray Obering. He's the head of the Missile Defense Agency. So this is not a statement from some conspiracy website. This is a statement from the head of the MDA. What did he say when he was speaking at a Homeland Security conference on a missile defense panel on October 13th in Colorado Springs, Colorado? He was asked about the THAAD, which is the Theater High Altitude Defense Missiles that are scheduled to go into production in 2005. He was asked about these. What did General -- General Henry Tray Obering say about the missiles? He said, quote, These missiles are intended to augment, not replace, the current generation of ground-based midcourse interceptors.	Section 4.1.4 shows that BMDS launches are only three times the number of non-BMDS U.S. launches instead of five times the number as indicated by the commenter. While projected BMDS launches may account for more launches than other U.S. launches, the size of the BMDS boosters would be on average much smaller than those used for other U.S. launches. Boosters were categorized based on the size of the propulsion system. As shown in Exhibit I-2 of Appendix I, all of the 515 projected BMDS launches fall within the low propellant size category. Therefore emissions loads to the stratosphere from BMDS project launches (shown in Exhibit I-6) are less than those for other U.S. launches (shown in Exhibits I-7 and I-8). The number of BMDS project launches outlined in Section 4.1.4 includes all launches related to BMDS operations, including targets and interceptors, and as such does include Terminal High Altitude Area Defense (THAAD) launches. Because the projected launches would include all potential launches and not just GBI launches, the proposed THAAD launches, which are intended to augment the GBI program, would be included in the projected numbers. Therefore, additional launches would not need to be analyzed for the cumulative impacts analysis.
Cumulative Impacts	PHO0023-5	The PEIS is insufficient in dealing with cumulative effects, especially in Southern California, as so many of our local contractors are working on the weapons systems. We're bearing the brunt of our environmental impacts of the laser weapon development and many of the rocket	The PEIS is a programmatic level NEPA analysis that considers implementation alternatives for an integrated BMDS and as such does not address specific sites or specific activities at those sites, but rather considers the program as a whole to allow tiering of subsequent site-

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		launches and the rockets that are being assembled for those launches to launch these 515 launches that may take place over the next 10 years.	specific analyses from the PEIS. Subsequent analyses for activities occurring at specific locations would consider the localized cumulative impacts of those proposed activities at each individual location.
Cumulative Impacts	PHO0044-2	There's some inconsistencies and confusion about cumulative impacts. This EIS estimates 515 launches in a ten-year period, the previous 2003 ground-based missile defense extended test range EIS estimated only 100 in a ten-year period.	The GMD ETR EIS analyzed a total of 100 launches over a 10-year period to validate the GMD ETR test program. The 515 launches analyzed in the PEIS include all launches that would occur as a part of the proposed BMDS including GMD program launches.
Cumulative Impacts	PHO0046-7	The cumulative impacts analysis I think was very flawed. You said earlier that you would only consider similar types of global actions in comparing what the cumulative impacts would be, but I think that's a way of effectively ignoring the combined effects of many, many local impacts that occur when you have these programs in many forms around the world. So I think you need to consider all those analyses, the local studies that are being done, that have been done, past, present and future.	The PEIS is a programmatic level NEPA analysis that considers implementation alternatives for an integrated BMDS and as such does not address specific sites or specific activities at those sites, but rather considers the program as a whole to allow tiering of subsequent site-specific analyses from the PEIS. Subsequent analyses for activities occurring at specific locations would consider the localized cumulative impacts of those proposed activities at each individual location.
Cumulative Impacts	PHO0048-6	Also, the cumulative impact analysis is also inadequate. NEPA requires that past, present, and future activities that may incrementally add up to accumulative impact on an area be assessed, but this PEIS is flawed for several reasons. First, it doesn't really consider past projects in the cumulative impact analysis. It says something to the effect of, well, there are things that had gone through NEPA assessment before and so we're not considering those now. This is obviously logically flawed. I mean, the EISs that we've gone through before, had any of them ever dreamed that there would be a missile defense thing shot from space? I mean, let's look at the Striker IS. We're all familiar with that. Does that mention at all anywhere	The cumulative impact of worldwide launch programs on ozone depletion and global warming does indeed consider the effects of past launch programs as MDA strives to determine impacts on an atmosphere already impacted in these areas by all previous launches. Ozone depletion is well documented as a phenomenon that is caused by complex chemical reactions due to release of chlorofluorocarbons and other industrial chlorine-containing chemicals into the stratosphere as well as other activities like rocket launches that create emissions that may impact ozone depletion. MDA's cumulative analysis takes a snapshot of the affected environment as it currently exists, already affected by years of launches

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		ballistic missiles? No. Okay. So clearly relying on a NEPA document published before this day is not going to give us an adequate analysis of whether it's a cumulative impact. In fact, there's a heck of a lot going on here caused by the military that never went through NEPA analysis.	and other chemical industrial activities in the past. It would be impossible to try to determine the past contribution of launch emissions to ozone depletion and with new regulatory controls the contribution of launch emissions may be increasingly important in the future. Therefore MDA elected to consider the potential contribution from worldwide government and commercial launch programs projecting a launch manifest forward in time from 2004 as an appropriate representation of the cumulative impacts of the BMDS program.
Cumulative Impacts	PHO0048-7	In addition, they also put this really interesting limitation on it that I've never seen before in an EIS, and I've read quite a few myself. It says, well, because this has a national and international nature to the impact of the ballistic missiles, they were only going to consider national/international cumulative impacts. That means only something that affects the entire continent, only if it affects the entire world. So we're not going to look at the unique situation of Hawaii. And what we are having to go through is the increasing militarization of Hawaii, and that's not sufficient. I mean, to really consider the cumulative impacts of this PEIS, we need to talk about things that are in the areas that are likely to be affected and likely to be caused harm.	The PEIS is a programmatic level NEPA analysis that considers implementation alternatives for an integrated BMDS and as such does not address specific sites or specific activities at those sites, but rather considers the program as a whole to allow tiering of subsequent site-specific analyses from the PEIS. As noted in Section 4.1.4 of the PEIS, the proposed BMDS is worldwide in scope. Therefore, it is appropriate to consider other worldwide activities, including U.S. and foreign commercial and foreign government launches, along with the proposed BMDS launches to estimate cumulative impacts.
Cumulative Impacts	PHO0049-1	The cumulative effects on the Marshallese people, for example, who have already been exposed to so much nuclear poison and now you want to add more toxic waste into their lagoons. And the accumulation, the additive factors, I think you have not even touched on how this is	The PEIS is a programmatic level NEPA analysis that considers implementation alternatives for an integrated BMDS and as such does not address specific sites or specific activities at those sites, but rather considers the program as a whole to allow tiering of subsequent site-specific analyses from the PEIS. Cumulative impacts

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		going to impact a group of people that have already suffered enough for us Americans.	from activities occurring in specific locations, such as the Marshall Islands, would be considered in subsequent analyses as appropriate.
Cumulative Impacts	PHW0006-1	1. The 515 projected BMDS launches that are evaluated by the PEIS do not include the intended expansion of the BMDS program, and thus does not meet criteria of the National Environmental Policy Act (NEPA). This intended expansion was described on October 13 by General Henry "Trey" Obering the director of the Missile Defense Agency (MDA). Speaking at the Homeland Security Conference in Colorado Springs General Obering was asked about the new Theater High-Altitude Area Defense (THAAD) missiles scheduled to move into production in late 2005. In response General Obering stated they will "augment, not replace, the current generation of ground-based midcourse interceptors. In fact, there will be a continued spiraling up of capabilities in both missile networks, with more missiles and additional sites being added for the current missiles, and an expansion of THAAD beyond the initial scheduled 25 missiles"	The number of BMDS project launches outlined in Section 4.1.4 includes all launches related to BMDS operations such as targets and interceptors and thus, does include THAAD launches. The projected launches would include all potential launches and not just ground-based midcourse interceptor launches. Therefore, the proposed THAAD launches, which are intended to augment the GBI program, would be included in the projected numbers and additional launches would not need to be analyzed for the cumulative impacts analysis.
Emissions	E0320-1	2. The hydrogen chloride injected into the atmosphere with each launch has incredible potential to neutralize ozone, enlarging the famous hole which now requires Australian school children to be outside only with hats and long-sleeved shirts.	The potential impacts from launches on the atmosphere are discussed in Section 4.1.1.2 of the PEIS. Specifically, the PEIS discusses the fact that atomic and molecular chlorine could be produced as a result of chemical reactions involving hydrogen chloride. Atomic and molecular chlorine have been shown to contribute to localized ozone depletion in the plume wakes of boosters. However, the PEIS found that based on the amount of chlorine produced, the large volume of air volume over which these emissions would be spread, and

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
			because of rapid dispersion by stratospheric winds, the active chlorine from launches would not contribute to significant localized ozone depletion. Therefore, it is unlikely that emissions from launches would lead to an increase in skin cancers due to a thinning of the stratospheric ozone layer.
Emissions	E0402-4	1) The result of release of hydrogen chloride, aluminum oxide, and hydrochloric acid into the upper atmosphere will consume huge amounts of ozone, resulting in dramatic increases in UV light exposure with epidemics of skin cancer, cataracts and the less studied but known effects on sensitive species such as amphibians and microscopic organisms.	See previous response.
Emissions	E0424-1	a) The planned heightened increase in missile launches would potentially lead to increased exposures to the population from toxic pollutants. These include liquid propellants containing hydrazines, nitrogen tetroxide, and other toxic compounds. In addition, the ammonium perchlorate used in solid propellants blocks the formation of key thyroid hormones which are critical for the growth and development especially in fetuses and children. The PEIS proposes to allow an over 30-fold higher level of perchlorate (200 parts per billion) than those proposed by the State of California (6 parts per billion). The numerous anticipated rocket launches will release chemicals including aluminum oxide, hydrogen chloride and hydrochloric acid into the upper atmosphere, with the potential for further depleting the diminished ozone layer. For example, each molecule of hydrogen chloride consumes 100,000 molecules of ozone, resulting in the widening of the ozone hole, thereby dramatically	The DoD and the MDA are aware of the potential health concerns associated with perchlorate contaminated water and of the various Federal and state initiatives to address this issue. In addition to citing the Perchlorate Study Group findings, the PEIS has been modified to include the proposed findings from the State of California Office of Environmental Health Hazard Assessment, the State of Massachusetts, and U.S. EPA. To better characterize some of the potential impacts associated with proposed BMDS activities, additional information and research on perchlorate has been added to Section 4.1.1.2 of the Final PEIS. Further, a technical Appendix M addressing issues specifically related to perchlorate has been added to the Final PEIS. The appendix considers the uses, sources, and disposal of perchlorate as well as the effects on human health and the environment.

Exhibit K-3. Responses to Comments – Environmental Impacts

		increasing levels of UV light. Elevated levels of UV light cause sunburn, skin cancer, cataracts, and many other forms of UV damage to sensitive species;	The potential impacts from launches on the atmosphere are discussed in Section 4.1.1.2 of the PEIS. Specifically, the PEIS discusses the possibility that ozone would be depleted through complex reactions with chlorine, aluminum oxide, and nitrogen oxides. The PEIS presents a discussion of these complex interactions and supports the determination that "Due to the large air volume over which [chlorine] emissions would be spread, and because of rapid dispersion by stratospheric winds, the active chlorine from launches would not contribute to significant localized ozone depletion.", "The exact magnitude of ozone depletion that can result from a build-up of Aluminum Oxide (Al_2O_3) over time has not yet been determined quantitatively, but appears to be insignificant based on existing analysis.", and "Stratospheric winds would disperse these quantities [of nitrous oxides] rapidly; therefore, no significant effect on ozone depletion would be expected from these emissions. (Molina, 1996 as referenced in U.S. Department of the Air Force, 1997a)
Emissions	E0427-5 and E0439-5	6) Not only does the BMDS PEIS under represent the total amount of emissions, from the estimated 515 BMDS rocket launches over the next several years, it also discounts that this program will be injecting large quantities of chemicals including aluminum oxide, hydrogen chloride and hydrochloric acid into the upper atmosphere, stratosphere, etc. Most concerning is the injection of hydrogen chloride into the upper atmosphere where the breakdown of each hydrogen chloride molecule to chloride ion catalyzed the breakdown of 100,000 ozone molecules, thereby depleting ozone, and decreasing the	See previous response.

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		blocking of UV rays. This depletion of ozone will increase risk of cataracts and skin cancer. Thus, the BMDS will have a much greater effect on ozone depletion and skin cancer than HC1 released at sea level.	
Emissions	E0427-4 and E0439-4	5) The BMDS PEIS did not adequately consider impacts of Hazardous waste and materials and on Health and safety, Water Resources and Biological resources of environmental contamination from toxic and hazardous components of rocket fuels and explosives. The BMDS PEIS markedly under reports the emissions of representative interceptors. Exhibit 4-11 reports the emission of (90+58+52+22+17+6+6)=251 pounds for a representative interceptor. However, ground based interceptors are much larger (approximately 54 feet long 3 stage solid propellant rockets (such as the Minuteman III) weighting 22.5 to 25 tons and containing approximately 30,000 to 45,000 pounds of solid propellant. Thus the MDA underestimates the emissions from such interceptor rockets by factor of greater than 100. This is totally unacceptable. This underestimate of BMDS pollutants is apparently repeated in Exhibits 4-13, 4-14 and 4-15. Thus the MDA needs to revaluate the environmental effects of these pollutants. Also the MDA should define what are the emissions from the missiles used to launch spaced based interceptors, and sensors.	The PEIS did consider the impacts of rocket propellants released into the environment from non-nominal launches or transport/handling spills as hazardous waste, on soils and water resources, on biological resources, and on health and safety. Further the PEIS analyzed the impacts of emissions from nominal launches of various propellant types in support of BMDS test activities. The interceptor emission products noted in Exhibit 4-11 are for a PAC-3 missile. Although all proposed integration test launches would not include the launch of a GBI, the exhibit has been updated to include the emissions from a GBI. As shown in the updated exhibit, even when considering the emissions from a target and a GBI, emissions would not exceed de minimis levels. Further, as noted in Appendix I, various sizes of boosters were considered in calculating the cumulative impact of BMDS launches. Therefore, Exhibits 4-13, 4-14, and 4-15 do not need to be updated. The emissions from the vehicles used to launch the space-based interceptors, sensors and other assets into space have been considered as part of support assets as defined and analyzed in the PEIS.
Emissions	E0429-2	Solid rocket propellant that contains ammonium perchlorate as an oxidizer is designed to generate large quantities of hydrogen chloride, which reacts with moisture in the atmosphere to create hydrochloric acid- that is, acid precipitation. The PEIS should consider how	The BMDS PEIS considers the use of a wide variety of propellants including three types of boosters, pre-fueled liquid propellant, non-pre-fueled liquid propellant, and solid propellant boosters. The environmental impacts of each of these three types of boosters are presented in

		the missile defense program might develop and test alternate launch technologies that are not so environmentally destructive.	Section 4.1.1.2 of the PEIS. In addition, a technical appendix (Appendix M) has been added to the PEIS that addresses issues specifically related to perchlorate. The appendix includes the alternatives that DoD is currently evaluating to the use of perchlorate in munitions.
Emissions	E0429-7, PHW0004-7, E0429-26, PHW0004-26	3. Evaluate alternative launch technologies not based upon ammonium perchlorate.	See previous response.
Emissions	PHW0004-2	Solid rocket propellant that contains ammonium perchlorate as an oxidizer is designed to generate large quantities of hydrogen chloride, which reacts with moisture in the atmosphere to create hydrochloric acid-that is, acid precipitation. The PEIS should consider how the missile defense program might develop and test alternate launch technologies that are not so environmentally destructive.	See previous response.
Emissions	E0429-3 and PHW0004-3	When rockets are launched into the upper atmosphere, they directly deliver hydrogen chloride to the ozone layer, exposing human, other animals, and other biota to the harmful, persistent effects of ultraviolet-B radiation (UVB). Rocket launches are among the largest causes of ozone depletion, and the persistence of such substances from other sources is no excuse for additional pollution. The BMDS program should at the very least evaluate the mitigation of such seriously harmful environmental consequences through the development and deployment of alternative solid rocket propellants.	The potential impacts from launches on the atmosphere are discussed in Section 4.1.1.2 of the PEIS. Specifically, the PEIS discusses the possibility that ozone would be depleted through complex reactions with chlorine, aluminum oxide, and nitrogen oxides. The PEIS presents a discussion of these complex interactions and supports the determination that "Due to the large air volume over which [chlorine] emissions would be spread, and because of rapid dispersion by stratospheric winds, the active chlorine from launches would not contribute to significant localized ozone depletion.", "The exact magnitude of ozone depletion that can result from a build-up of Al_2O_3 over time has not yet been determined quantitatively, but appears to be insignificant

			based on existing analysis.", and "Stratospheric winds would disperse these quantities [of nitrous oxides] rapidly; therefore, no significant effect on ozone depletion would be expected from these emissions. (Molina, 1996 as referenced in U.S. Department of the Air Force, 1997a)" The BMDS PEIS considers the use of a wide variety of propellants including three types of boosters, pre-fueled liquid propellant, non-pre-fueled liquid propellant, and solid propellant boosters. The environmental impacts of each of these three types of boosters are presented in Section 4.1.1.2 of the PEIS. In addition, Appendix M includes DoD-wide research initiatives under the Strategic Environmental Research and Development Program that have focused on the development of more environmentally-friendly launch technologies, such as missile propellants that do not use ammonium perchlorate as an oxidizer. While these alternate propellant formulations have showed promise, a significant amount of development remains to optimize the formulation for specific missile systems. In addition, these formulations will go through a lengthy and stringent performance and safety certification process. Since these alternative technologies are in a research and development phase and are not yet advanced enough for their use to be reasonably foreseeable under NEPA, they are not analyzed in this PEIS. The MDA may consider the use of these alternative environmentally-friendly technologies as they become available in the future and meet the operational test requirements for the BMDS.

Issue Topic	Comment Number	Excerpt Text	Response
			Among launch technologies that are available today, the BMDS PEIS considers a wide variety of propellants used in three types of boosters, pre-fueled liquid propellant, non-pre-fueled liquid propellant, and solid propellant boosters. The environmental impacts of each of these three types of boosters are presented in Section 4.1.1.2 of the PEIS.
Emissions	PHO0011-1	As we know, the -- the perchlorates are used in the self-propellants in the formation of a key thyroid hormone which are critical for growth and development of fetuses and children. The PEIS proposes to allow over thirty-fold higher levels of perchlorate at 200 parts per billion than proposed by the State of California, which is six parts per billion. Thus, many rocket launches will inject chemicals including aluminum oxide, hydrogen chloride and hydrochloric acid directly into the upper atmosphere, thereby depleting the ozone. The PEIS does not address the direct injection of the chemicals high into the atmosphere.	The DoD and the MDA are aware of the potential health concerns associated with perchlorate contaminated water and of the various Federal and state initiatives to address this issue. In addition to citing the Perchlorate Study Group findings, the PEIS has been modified to include the proposed findings from the State of California Office of Environmental Health Hazard Assessment, the State of Massachusetts, and U.S. EPA. To better characterize some of the potential impacts associated with proposed BMDS activities, additional information and research on perchlorate has been added to Section 4.1.1.2 of the Final PEIS. Further, a technical Appendix M addressing issues specifically related to perchlorate has been added to the Final PEIS. The appendix considers the uses, sources, and disposal of perchlorate as well as the effects on human health and the environment. The potential impacts from launches on the atmosphere are discussed in Section 4.1.1.2 of the PEIS. Specifically, the PEIS discusses the possibility that ozone would be depleted through complex reactions with chlorine, aluminum oxide, and nitrogen oxides. The PEIS presents a discussion of these complex interactions and supports the determination that "Due to the large air

			volume over which [chlorine] emissions would be spread, and because of rapid dispersion by stratospheric winds, the active chlorine from launches would not contribute to significant localized ozone depletion.", "The exact magnitude of ozone depletion that can result from a build-up of Al_2O_3 over time has not yet been determined quantitatively, but appears to be insignificant based on existing analysis.", and "Stratospheric winds would disperse these quantities [of nitrous oxides] rapidly; therefore, no significant effect on ozone depletion would be expected from these emissions. (Molina, 1996 as referenced in U.S. Department of the Air Force, 1997a)
Emissions	PHO0025-2	Further, rocket launches deliver hydrochloric acid in the upper atmosphere which, in turn, chemically interact with the protective ozone layer. It is therefore fair to assume that an increase in rocket launches may correspondingly bring about additional cases of skin cancer.	The potential impacts from launches on the atmosphere are discussed in Section 4.1.1.2 of the PEIS. Specifically, the PEIS discusses the fact that atomic and molecular chlorine could be produced as a result of chemical reactions involving hydrogen chloride produced from SRMs. Atomic and molecular chlorine have been shown to contribute to localized ozone depletion in the wake of SRM boosters. However, the PEIS found that based on the amount of chlorine produced, the large volume of air volume over which these emissions would be spread, and because of rapid dispersion by stratospheric winds, the active chlorine from SRM launches would not contribute to significant localized ozone depletion. Therefore, it is unlikely that emissions from MDA test launches would lead to an increase in skin cancers due to a thinning of the stratospheric ozone layer.

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
Emissions	E0162-11	9)There are egregious errors in Exhibit 4-11 on page 4-102. There is an addition error in the line for HC1 emissions. The more serious error is that the total emissions of 115 kilograms for the representative interceptor is too small by a factor exceeding 100. Table 4.1.1-8 of the 2003 GMD ETR Final EIS gives total stage 1 exhaust emissions of greater than 15,000 kilograms. The GBI analyzed in that EIS had a total propellant mass of 19,767 kilograms of which 15,069 was in stage 1. The PEIS notes on page D-20 that each GBI may contain up to 20,500 kilograms of solid propellant. Exhibit 4-11 should be corrected; the information for BMDS launches in Exhibits 4-13, 4-14, and 4-15 may need correction if it is based on the interceptor data in Exhibit 4-11.	Addition error has been addressed. The interceptor emission products noted in Exhibit 4-11 of the Draft PEIS are for a PAC-3 missile. Although all proposed integration test launches would not include the launch of a GBI, the exhibit has been updated to include the emissions from a GBI. As shown in the updated exhibit, even when considering the emissions from a target and a GBI, emissions would not exceed de minimis levels. Further, as noted in Appendix I, various sizes of boosters were considered in calculating the cumulative impact of BMDS launches. Therefore, Exhibits 4-13, 4-14, and 4-15 do not need to be updated.
Emissions	PHO0044-3	There's an egregious error in Exhibit 4-11 on page 4-102. First of all, there's an addition error in the table. The more serious error is that total emissions for the interceptor are given as 115 kilograms, whereas the 2003 EIS for the ground-based interceptor gave the first stage emissions as 15,000 kilograms. So what's given in this EIS is a factor of 100 too small.	See previous response.
Emissions	E0427-5 and E0439-5	6) Not only does the BMDS PEIS under represent the total amount of emissions, from the estimated 515 BMDS rocket launches over the next several years, it also discounts that this program will be injecting large quantities of chemicals including aluminum oxide, hydrogen chloride and hydrochloric acid into the upper atmosphere, stratosphere, etc. Most concerning is the injection of hydrogen chloride into the upper atmosphere	The potential impacts from launches on the atmosphere are discussed in Section 4.1.1.2 of the PEIS. Specifically, the PEIS discusses the fact that atomic and molecular chlorine could be produced as a result of chemical reactions involving hydrogen chloride. Atomic and molecular chlorine have been shown to contribute to localized ozone depletion in the wake of boosters. However, the PEIS found that based on the amount of

		where the breakdown of each hydrogen chloride molecule to chloride ion catalyzed the breakdown of 100,000 ozone molecules, thereby depleting ozone, and decreasing the blocking of UV rays. This depletion of ozone will increase risk of cataracts and skin cancer. Thus, the BMDS will have a much greater effect on ozone depletion and skin cancer than HC1 released at sea level.	chlorine produced, the large volume of air volume over which these emissions would be spread, and because of rapid dispersion by stratospheric winds, the active chlorine from launches would not contribute to significant localized ozone depletion. In addition, the PEIS considers the possibility that ozone would be depleted through complex reactions with chlorine, aluminum oxide, and nitrogen oxides. The PEIS presents a discussion of these complex interactions and supports the determination that "Due to the large air volume over which [chlorine] emissions would be spread, and because of rapid dispersion by stratospheric winds, the active chlorine from launches would not contribute to significant localized ozone depletion." "The exact magnitude of ozone depletion that can result from a build-up of Al_2O_3 over time has not yet been determined quantitatively, but appears to be insignificant based on existing analysis.", and "Stratospheric winds would disperse these quantities [of nitrous oxides] rapidly; therefore, no significant effect on ozone depletion would be expected from these emissions. (Molina, 1996 as referenced in U.S. Department of the Air Force, 1997a)" Therefore, it is unlikely that emissions from launches would lead to an increase in skin cancers due to a thinning of the stratospheric ozone layer.
Environmental Justice	E0363-2	Certainly, those individuals (often consisting of minority ethnic groups) and non-human species who live on or near test sites are at particular risk, and this issue is not sufficiently addressed in the PEIS.	The fair treatment and meaningful involvement of all people regardless of race, color, national origin, or income with respect to the development, implementation, and enforcement of environmental laws,

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
			regulations, and policies is defined as environmental justice. Environmental justice is discussed in Section 3.1.5 of the PEIS. This programmatic analysis does not consider impacts at specific locations or sites; therefore, it is not possible to perform a meaningful environmental justice analysis as directed by Executive Order (EO) 12898; however, a roadmap for subsequent tiered analyses is included in Section 3.1.5. As specific locations are identified for possible BMDS activities tiered site-specific analyses would consider environmental justice.
Environmental Justice	PHO0025-5	There should also be an environmental health evaluation concerning cumulative impacts for military production, testing and deployment of missile defense systems compounded on top of past military use. This evaluation should be done with an eye on disproportionate impacts on low-income communities of color.	See previous response.
Environmental Justice	PHO0046-8	And this gets to the environment justice analysis, which is also flawed and inadequate. There is an adverse and significant impact on native peoples here in Hawaii, in Greenland, Enewetak in the Marshall Islands, and in other places, Alaska and so forth, and you did not look at how this program has a disparate effect on those peoples, their culture, their resources, and actually their survival. So please consider those.	See previous response.
Environmental Justice	PHO0051-7	Also, Ohana Koa believes that Star Wars will have a significant adverse impact on native Hawaiians, our Marshall Island brothers and sisters, the Enewetaks, and other indigenous peoples; and that the Programmatic	See previous response.

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		Environmental Impact Statement fails to consider these impacts.	
Environmental Justice	M0268-4	Effect of hazardous and toxic waste on minority communities: As an organization we have a strong concern for human rights and racial justice. We note that the Environmental Impact Assessment requires consideration of undue negative impact on minority communities. It is our understanding that the test sites are mainly on Indian lands or on lands belonging to Marshall Islanders. The statement in the PEIS that "Environmental justice analyses require information about local communities, and therefore will be analyzed in site specific environmental documentation. " is hardly adequate. We know what damage has been done to such communities already by bombing ranges (as in Puerto Rico) or nuclear weapons testing (as in the South Pacific and on Indian lands in the U.S. southwest). Such an analysis should have been made before the deployment and testing began. The program should be halted until thorough analysis is made, and it should not continue if there is evidence of detrimental effect on these populations and their environment.	See previous response.
Hazardous Materials Hazardous Waste	E0395-13	The PEIS does not present the total quantities of specific hazardous chemicals that would be carried aboard an ABL aircraft nor does it describe the total quantities of specific hazardous chemicals that would be stored on the ground at various test and training locations. In addition, the PEIS does not address the environmental impacts should those chemicals be spread over the land from an accident or aircraft crash, or jettisoned at low altitude in an emergency.	The PEIS is a programmatic analysis and is intended to serve as a tiering document for future site-specific analyses. Therefore, it is not possible to consider the total quantities of specific hazardous materials that would be used at a specific facility. Future tiered analyses would need to consider the impacts associated with the quantities of hazardous materials used and hazardous waste generated as a result of a particular action or test. The PEIS presents information on the

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
			potential environmental impacts of possible failure scenarios for various components including laser weapons operating from air environments. In addition, the amounts of chemicals used in the ABL are provided in the EIS for the Program Definition and Risk Reduction Phase of the Airborne Laser Program (U.S. Department of the Air Force, 1997b) and Airborne Laser Program Supplemental EIS (MDA, 2003a), which are incorporated by reference (as listed in Appendix C).
Hazardous Materials Hazardous Waste	E0429-22	The PEIS should consider the environmental consequences of various disposal strategies so the BMDS program can develop the technology or capacity to address its waste or consider the use of alternative launch technologies or strategies to minimize either the waste or the negative environmental impacts.	The BMDS PEIS considers the use of a wide variety of propellants including three types of boosters, pre-fueled liquid propellant, non-pre-fueled liquid propellant, and solid propellant boosters. The environmental impacts of the use of each of these three types of boosters are presented in Section 4.1.1.2 of the PEIS. The BMDS must rely on the most appropriate launch technology to support the development, testing, deployment, and decommissioning of an integrated missile defense capability. Many of the boosters used as target missiles for the BMDS would already have been manufactured for other DoD programs, which are in inventory and no longer needed. The MDA will continue to use appropriate disposal strategies to handle hazardous materials and waste. The environmental impacts of hazardous materials and hazardous waste generated from launch related activities are considered in Section 4.1.1.2 of the PEIS.
Hazardous Materials Hazardous	PHW0004-22	The PEIS should consider the environmental consequences of various disposal strategies so the BMDS program can develop the technology or capacity to address	See previous response.

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
Waste		its waste or consider the use of alternative launch technologies or strategies to minimize either the waste or the negative environmental impacts.	
Hazardous Materials Hazardous Waste	F0006-1	1. NOAA Fisheries recommends that the Missile Defense Agency be responsible for handling and disposing of all hazardous materials or hazardous wastes in all phases of the proposed action in accordance with applicable Federal, state, and local laws, utilizing best management practices at all life cycle activities of the proposed action and through appropriate project planning and design measures including appropriate spill prevention, control and contingency plans (e.g., Oil Discharge Prevention and Contingency Plan, Storm Water Pollution Prevention Plan) for each site.	The disposal of all hazardous materials and hazardous wastes would be conducted in compliance with applicable Federal, state, and local laws. Project planning would take spill prevention, control, and contingency planning into account to ensure compliance with all relevant regulations.
Health and Safety	E0319-10	The BMDS Draft PEIS discusses ground testing of 'portable' lasers, but does not list all the potential test sites. A September 2004 ABC news report stated a Delta Airlines pilot received an eye injury when a laser beam came through the cockpit window on his approach to the Salt Lake City, Utah airport. There have been no further reports regarding where the laser beam originated; however, it leaves open the possibility of whether some ground-based or air-based laser tests were going on at the High Energy Laser Systems Test Facility located at the White Sands Missile Range in New Mexico and the Delta Airlines pilot happened to get caught in the laser's crossfire. Utah and New Mexico are within close proximity in air miles. As stated in the Draft PEIS (Volume 1, page 4-21 thru 4-34), environmental and human health hazards would result from testing air based and ground based 'portable' lasers, which is: cancer	As referenced in the comment, the PEIS discusses the potential impacts on health and safety and biological resources from the activation and use of laser weapons (Section 4.1.1.1) and laser sensors (Section 4.1.1.5). If it is determined that laser weapons or laser sensors need to be tested at specific locations, the environmental impacts of their use at these locations would be considered in subsequent site-specific NEPA analyses tiered from this PEIS, as appropriate.

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		causing chemical releases into the air and waters, potential skin burns and retina damage from laser beams and/or laser 'scatter', hazards to commercial and other aircraft, birds, plants and wildlife. "Hydrochloric acid produced as a result of the interaction between laser emissions and moisture in the air has the potential to produce impacts on biological resources, including plants and aquatic animals, and water quality" (Draft PEIS Volume 1, page 4-23). "Exhaust emissions from laser activation have the potential to harm human health." "Laser beams can cause serious health problems if they contact the skin or eyes" (Volume 1, page 4-34).	
Health and Safety	E0319-18	The safety hazards of launching interceptors from the KLC should have been discussed in the Draft PEIS, considering the high winds which occur on Kodiak Island throughout the year-- peak gusts up to 35 miles per hour in June and 83 miles per hour in December (PEIS Volume 2, Page H-18, Section H.2.1-Air Quality). As Kodiak residents have previously pointed out to the MDA in other EA comments (which the MDA has ignored), launching missile targets, and now possibly interceptors in a southwest trajectory down the East side of Kodiak Island would be extremely risky and potentially hazardous should a launch accident occur, because of populated native villages (e.g. Old Harbor and Akhiok) which are within the 'explosive safety hazard zone'.	The GMD ETR EIS did analyze the environmental impacts of launching interceptors from KLC. However, the MDA announced in a ROD that there were currently no plans to launch interceptors from KLC. This is still the case. The environmental impacts of conducting launch activities from the KLC have been considered in a number of earlier NEPA analyses. Site-specific environmental analyses tiered from this PEIS will be conducted for future proposed activities at specific sites such as the KLC, as appropriate.
Health and Safety	E0319-23	Executive Order 13229 (October 9, 2001) does not change the requirements of EO 13045 (April 21, 1997), it only amends section 3-306 of that order "for a period of 4 years from the first meeting" and inserting in lieu thereof "for 6 years from the date of this order". The PEIS cannot	In considering the potential impacts to health and safety from the BMDS as described in Section 4 of the BMDS PEIS, the MDA did not identify any environmental health and safety risks that may disproportionately affect children.

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		identify environmental health and safety risks if the Department of Defense (MDA) has not requested any studies on the issue.	
Health and Safety	E0319-25	Executive Order 13045, Section 1. Policy 1-101 states: "A growing body of scientific knowledge demonstrates that children may suffer disproportionately from environmental health risks and safety risks. These risks arise because: children's neurological, immunological, digestive, and other bodily systems are still developing; children eat more food, drink more fluids, and breathe more air in proportion to their body weight than adults". Section 2-203, "Environmental health risks and safety risks means risks to health or safety that are attributable to products or substances that the child is likely to come into contact with or ingest (such as the air we breathe, the food we eat, the water we drink or use for recreation, the soil we live on, and the products we use or are exposed to)". Once again, refer to Draft PEIS Volume 2, pages H-18, H-19-Existing Emission Sources; "Most sites where activities for the proposed BMDS may occur would be classified as a major emissions source". It is the major emission sources related to MDA activities, which has the people living near launch test sites concerned. The PEIS should include ALL test sites locations that will be affected by future BMDS activity.	The MDA complies with all applicable regulations to address disproportionate risks to children that result from environmental health risks or safety risks. The MDA strives to protect human health (including that of our children) and the environment while carrying out its mission. The definition used for "major source" in the PEIS is the same that is used in the Clean Air Act Section 112(a)(1). This section defines "major source" as "any stationary source or group of stationary sources located within a contiguous area and under common control that emits or has the potential to emit considering controls, in the aggregate, 10 tons per year or more of any hazardous air pollutant (HAP) or 25 tons per year or more of any combination of HAPs. The Administrator may establish a lesser quantity, or in the case of radionuclides different criteria, for a major source than that specified in the previous sentence, on the basis of the potency of the air pollutant, persistence, potential for bioaccumulation, other characteristics of the air pollutant, or other relevant factors." Site-specific environmental analyses will be conducted for future proposed activities at specific locations, as appropriate.
Health and Safety	E0380-1	1) In category after category, case after case, the PEIS repeatedly discounts the impacts of toxic substances resulting from and involved in activities at every level - manufacture, launching, use, etc. - by contending that the toxic substances will have no impact because they will be handled in accordance with existing law and guidelines.	As stated in the PEIS, the MDA would comply with all applicable regulations and requirements regarding the use and disposal of toxic substances. In addition, activities proposed at specific ranges/facilities will comply with applicable mitigation measures that apply to

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		Such a blanket contention flies in the face of current experience with toxic substances. Many factors result in the legal guidelines failing to insure public and environmental safety when toxic substances are involved. The report fails to entertain the possibility of accidental spills and discharges, whether in the transportation stage or as a consequence of mishaps at other stages. Additionally, the report ignore our experiences in which we have repeatedly experienced toxic consequences from currently legal uses of chemicals. The claim that there will be no toxic impacts by merely following existing handling rules is implausible. Moreover, new discoveries about the minute amounts of substances that can still have a deleterious effect are continually forcing us to readjust safety standards. To initiate the massive undertakings proposed within the BMDS without making any attempt to mitigate the impacts - readily imaginable based on the evolving nature of toxin safety understandings - is unrealistic.	the specific range/facility where the actions are proposed to occur. The potential impacts associated with the accidental release of toxic substances including laser chemicals and booster propellants are discussed in Sections 4.1.1.1 and 4.1.1.2 of the PEIS.
Health and Safety	E0425-1	Please factor an inhalation pathway for exposure to ammonium perchlorate. Please assess for both public and occupational exposure. For toxicity information on this newly discovered pathway please see the following study.	The acute toxic effects found in the referenced study occurred when high levels of ammonium perchlorate were injected into rats' lungs. Available research suggests that the possibility of ammonium perchlorate inhalation is small because there is little or no residual perchlorate left after combustion of the solid propellant. This research would suggest that any exposure to ammonium perchlorate through air would not be at a high enough level to cause these kinds of effects.

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
			The MDA has reviewed available research on perchlorate and developed an appendix (see Appendix M) to the PEIS which provides additional information on the potential human health impacts of perchlorate.
Health and Safety	E0427-11 and E0439-11	The BMDS PEIS (page 4-32) cites that exposure to a reflected laser beam while in the air operating environment would be very short, < 0.01 seconds that and would not impact the health and safety (US Air Force 1997A). But no estimates are provided for the actual danger zone for the HEL to detrimentally affect health and safety, e.g. causing skin and especially retinal damage. The Draft Supplemental Environmental Impact Statement for the Airborne Laser Program (2002) (page 99) cites the power of the HEL as about 107 watts per square centimeter. Ten million watts per square centimeter will burn retinas and eyeballs very quickly. While the PEIS states that medium energy lasers such as the SHEL if focused at point 12 km away, would be hazardous to the human eye 2 km before to 2 km past the focus point. Where as the other lasers and especially the HEL would be hazardous immediately after leaving the turret of the ABL. While the PEIS states that the BILL and TILL no hazard distance would extend > 10 km beyond the target, and the HEL hazard distance would extend even beyond these distances. But the BILL, TILL and I presume the HEL hazard distances are apparently classified. How can the public comment on the effects of the BILL TILL and especially the HEL on health and safety if the distance at which these lasers cause eye damage is not available? The public and the MDA / Air force need to make this	As referenced in the comment, the PEIS discusses the potential impacts on health and safety and biological resources from the activation and use of laser weapons (Section 4.1.1.1) and laser sensors (Section 4.1.1.5). If it is determined that laser weapons or laser sensors need to be tested at specific locations, the environmental impacts of their use at these locations would be considered in subsequent site-specific NEPA analyses tiered from this PEIS, as appropriate.

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		information available to better ensure the heath and safety of the public.	
Health and Safety	E0427-12 and E0439-12	The PEIS focuses on the testing of these lasers, but fails to reveal whether once deployed, the ABL or any other BMDS weapons lasers will ever be directed toward aircraft including airliners, or individuals on the surface of the earth, e.g. on land or at sea. If so, the MDA needs to address the effects of HEL and other weapons lasers on endangering health and safety, especially skin and eye damage.	The ABL is designed to intercept threat missiles in the boost phase of flight. The ABL would be deployed to and operate in areas where boost-phase intercepts could be attempted. Its effectiveness is undergoing thorough testing as an integral component of the BMDS boost phase defense. The MDA has no plans to use the ABL for terrestrial targets.
Land Use	M0275-4	Page 3-31: In the portion titled "Impact assessment," we suggest referencing the Service National Wildlife Refuges.	A reference to the Service National Wildlife Refuges has been added to the BMDS.
Orbital Debris	F0005-14	Nor would the back-of-the-envelope dismissal of debris, orbital and otherwise. Frequently the PEIS posits that such debris poses a small risk, and downgrades the threat - which would come as a great surprise to our partners in the International Space Station. LAWS adopts and incorporates here by reference the compelling exposition of the dangers from space debris set out in the October 18, 2004 testimony of Theresa Hitchens, Vice President and Director of Space Security of the Center for Defense Information. This is a dramatically fatal flaw in the PEIS; one that ought not be swept under the NEPA rug.	Specific altitudes at which high altitude ground-based intercepts would take place are not provided in the BMDS PEIS. MDA has not underestimated the risk to spacecraft and the space environment. For every flight test, a detailed and comprehensive assessment of the risks posed to spacecraft is conducted. The risk assessment calculates the probability of impact between intercept debris and spacecraft as a function of time in a launch window. These calculations are not "back of the envelope" approximations of the risk; rather they account for both spatial and temporal changes in intercept debris flux, satellite area, satellite dwell time within the cloud, and so forth. The analysis allows mission planners and test conducters to determine the safest time to conduct a flight test minimizing the risk to both manned and unmanned spacecraft.

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
			Analysis shows that most of the intercept debris (>90%) reenters within six hours of the intercept. The remaining debris spreads into the background of space where it becomes indistinguishable from the background debris that has accumulated over decades of space operations. In fact, background debris poses a far greater risk to the International Space Station (ISS) than intercept debris. Testing of space-based interceptors would only be conducted in areas where airspace had been cleared. For debris reentering in an uncontrolled manger, most debris would not be expected to survive the severe heating and other forces during reentry. During the past 40 years an average of one cataloged piece of debris fell back to Earth each day and no serious injuries or significant property damage has been confirmed. As stated in Section 4.2.1, during testing the MDA would design flight test scenarios so that interceptor and target debris impacts in designated areas within the ocean or on cleared land-based ranges. Because the development of a space-based test bed is too speculative to be analyzed in this PEIS, the specific impacts of launching interceptors from space-based platforms for BMDS testing would be considered in subsequent analyses as appropriate. The MDA wanted to consider the broad possibilities of space-based interceptors as an alternative strategy to enhance the integrated BMDS recognizing that the technologies for this application are in initial stages of planning and development and that

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
			subsequent NEPA analyses would likely be needed as technologies and plans became more mature. The MDA has created a technical appendix to the PEIS (see Appendix L), which provides additional information on the creation, reentry, and disposition of orbital debris.
Orbital Debris	PHO0002-3	Major inadequacies in the PEIS treatment of issues related to debris include: Number one: the PEIS severely understates the potential threats to satellites and spacecraft, as well as to people and objects on the ground, from orbital debris caused by ground-based midcourse interceptor tests.	See previous response.
Orbital Debris	PHO0002-4	The PEIS fails to support its claim that little debris would be created because of lack of adequate modeling of likely debris creation from realistic testing of the ground-based interceptor, which would involve higher speed impacts at higher altitudes than testing so far. Under realistic testing of GBIs, ground-based interceptors, there is a significant chance that debris could be created that would last for years, not simply the months as asserted by the PEIS.	See previous response. Also note hypervelocity intercepts create debris. As stated earlier, most of the debris reenters within a few hours of the intercept. Detailed analysis of the risks posed to spacecraft is conducted as part of the mission planning process.
Orbital Debris	PHO0023-6	Last but not least, I would also suggest that you conduct a space debris analysis, as you have sited in the PEIS, that there may be intercepts as high a 400 kilometers. That either you do testing at 400 kilometers, which is ill-advised because of the debris problem, but how would you know if the weapons work unless you conduct the tests? Or you should actually assume that the weapons won't work because you cannot conduct the tests at 400 kilometers above.	See previous response.

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
Orbital Debris	PHO0037-3	Third, it neglected to look at space debris from high altitude midcourse missile intercepts or destruction of satellites, and it really glossed over potential impacts of debris falling to earth. It just wrote them off as being burned up in the atmosphere.	See previous response.
Orbital Debris	PHW0003-2	Ground-based interceptors will create debris in LEO if they impact their targets (Intercontinental Ballistic Missiles [ICBMs] fired at the United States) in the so-called mid-course phase, when they are outside the Earth's atmosphere. In this phase, the ICBM will be either rising into LEO, at the peak of its trajectory, or starting to descend back through space into the atmosphere. The PEIS states, "The amount of orbital debris could increase from .. .Ground-based Midcourse Defense ... . Such increases in orbital debris would be temporary, as studies indicate that objects in orbit between 200 and 399 kilometers (123 to 248 miles) reenter the atmosphere within a few months." This statement, however, is somewhat misleading. Up to now, MDA has been configuring ground-based, mid-course intercept tests so as to avoid debris creation, conducting tests at low altitudes and slow speeds, with both interceptor and target on a downward trajectory, so debris created will rapidly reenter the atmosphere.	See previous response.
Orbital Debris	PHW0003-7	Second, even if "best guesses" about a SBI configuration are used based on previously proposed and internal MDA designs, the PEIS fails to take into account the issues mentioned above regarding altitude, size and persistence of debris created by midcourse intercepts, and likely dangers to spacecraft from it.	See previous response.

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
Orbital Debris	PHW0001-6	As Ms. Hitchins makes clear, the PEIS fails to adequately analyze and discuss the possible dangers of debris in space. If the missile defense program has an Achilles heel, this is it. It is inexcusable for the MDA not to have undertaken or provided adequate scientific review of the physics involved in debris creation and re-entry, as well as of the multiple scenarios for missile defense intercepts. The dangers to people, and to objects in the air and on the ground are real, yet the PEIS blithely ignores such dangers. Depending upon the missile trajectory, debris could also be a threat to Canadian citizens, aircraft and ground facilities. As Ms. Hitchens notes, all T trajectories to the continental US from North Korea pass over both Canada and Russia, so that both nations are potentially at risk from boost-phase shortfall.	As noted in Section 4.1.1.2 of this PEIS, trajectory modeling would be conducted to verify that launch-related debris would be contained within predetermined areas, all of which would be located away from land and populated areas. The MDA has created a technical appendix to the PEIS (see Appendix L), which provides additional information on the creation and reentry of orbital debris.
Orbital Debris	PHW0002-4	Nowhere is this dismissive attitude indicated more clearly than in how the draft PEIS treats debris, orbital and otherwise. Orbital debris is listed as a resource consideration "because of the likelihood of orbital debris occurring from various launch and testing activities and its potential for impact to health and safety and the environment." (p. ES-12) Yet in every case that orbital debris is detailed as resulting from the proposed actions, it is written off as a non-threat to space assets or the terrestrial environment. It is claimed that the orbital debris from booster failure, for example, would be on-orbit for too little time to create damage, and that it would burn up upon re-entry, but even if it didn't, the likelihood of damage is small, (p. ES-21) This same justification is repeated ad nauseum throughout the document. The draft PEIS does admit that the International Space Station (ISS)	Analysis shows that most intercept debris reenters (>90%) within six hours of the intercept. The remaining debris spreads into the background of space and becomes a part of the background debris field. NASA estimates that there are several hundred million particles of background debris (> 1mm). Intercept debris adds a very small fraction (< 1%) to the overall background debris. Hence the overall background debris count and the resulting risk do not change appreciably. Many orbiting structures can practice collision avoidance, or alterations of their orbit, to avoid cataloged debris. Please note that the U.S. Air Force's Space Control Center indicated that the ISS has practiced collision avoidance six times; however, similar maneuvers are conducted on an approximately monthly

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		may be affected by orbital debris, but again downgrades the threat, saying that the ISS could merely do collision avoidance to ensure its safety, (p. ES-39) This no doubt comes as surprise to our partners in the ISS who were unaware that we were planning on weapons systems that very well could destroy our joint effort unless valuable fuel was used to effect a collision avoidance strategy. This dismissal of the threat of orbital debris to space assets contradicts statements made elsewhere in the draft PEIS. The document discloses that "little advance warning could be given to clear air space" if an SBI had an uncontrolled reentry, (p. 4-121) And, with a nod to the unpredictable, the document says, "Objects reentering may skip off the Earth's atmosphere, similar to a stone skipping across a pond, causing them to impact much farther away than originally predicted." (p. 4-122) Despite this, the document still clings stubbornly to the conclusion that orbital debris would have no significant impact.	basis to maintain orbital altitude. The MDA, however, would conduct pre-flight launch window screening to ensure that high altitude tests would only be conducted when ISS would not pass through the resulting debris clouds. Testing of space-based interceptors would only be conducted in areas where airspace had been cleared. For debris reentering in an uncontrolled manner, most debris would not be expected to survive the severe heating and other forces during reentry. During the past 40 years an average of one cataloged piece of debris fell back to Earth each day and no serious injuries or significant property damage has been confirmed. The MDA has added an appendix to the PEIS (Appendix L), which provides additional information on the creation, reentry, and disposition of orbital debris.
Orbital Debris	PHO0002-1	The overall assumption of the PEIS is that there is a low-level risk from either orbital debris or debris reentering the Earth's atmosphere, and that is not supportable, due in large part to the failure of the MDA to undertake and provide adequate scientific review of the physics involved in debris creation and reentry from the multiple possible scenarios for missile defense intercepts.	MDA has conducted an exhaustive study on this subject. Results are being coordinated with the space community. Testing would be conducted such that intercept debris would fall into the open ocean or over restricted land areas. MDA has conducted modeling of high altitude ground-based intercepts. This modeling has shown that the majority of post-intercept debris resulting from high altitude intercepts would reenter the atmosphere within a few hours. A small amount of post-intercept debris may become orbital debris; however, risks to spacecraft from this debris are less than the risk posed by existing background debris. The MDA has created a technical

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
			appendix to the PEIS (see Appendix L), which provides additional information on the creation and reentry of orbital debris.
Orbital Debris	PHW0003-1	The PEIS, however, dramatically fails to address the potential dangers (both to space-based objects and those on the Earth) from space debris that MDA admits will be created by testing or use of ballistic missile interceptors. The PEIS states (p. ES-33): "Proposed BMDS space-based sensor activities would be expected to produce small quantities of debris, primarily explosive bolts and small pieces of hardware. It may be possible for debris from an exoatmospheric intercept to become orbital debris. However, because the majority of the BMDS activities would occur in Low Earth Orbit where debris would gradually drop into successively lower orbits and eventually reenter the atmosphere, the debris would not be a permanent hazard to orbiting spacecraft. As BMDS testing becomes more realistic, there is a potential for an increased amount of debris reaching and remaining on orbit. A large portion of this debris would likely not remain on orbit for more than one revolution, and eventually all of the debris would be expected to de-orbit." While these statements are perhaps true, they also serve to downplay the possible dangers of debris. The overall assumption in the PEIS that there is a low-level of risk is not supportable, due to the failure of MDA to undertake or provide adequate scientific review of the physics involved in debris creation and reentry, as well as of the multiple scenarios for missile defense intercepts. The following is	See previous response.

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		an overview of the major inadequacies in the PEIS treatment of issues related to orbital debris.	
Orbital Debris	PHO0002-6	Finally, the PEIS asserts that most of the debris created in low Earth orbit would be small and thus not a major hazard to the ISS. Unfortunately, as I said, even tiny pieces of debris could destroy the ISS or other space assets. In actuality, small debris is considered by space operators as a bigger hazard to space objects because it cannot be detected and tracked adequately enough to allow planning for evasive maneuvers by those space objects that can do so. In other words, smaller debris could be a bigger threat to the ISS and other craft than larger pieces on orbit, and the PEIS undertakes no review of this fact of physics.	See previous response.
Orbital Debris	PHW0003-3	In the last successful test in October 2002, the interceptor hit the target at an altitude in excess of 210 kilometers (140 miles) above the Earth, at a speed of about half of what would be required in a real-life scenario. Realistic testing and employment of a ground-based mid-course system would require intercepts at higher altitudes orbit of around 300+ kilometers and extremely high speeds, and would more likely take place with both the interceptor and the target flying in an upward trajectory - facts of physics that would lead to the creation of more debris and likely result in debris being flung into a higher orbital plane than the altitude of the intercept itself. If the debris ends up orbiting at higher than 399 kilometers, it could remain in space for years. There is no evidence that the PEIS takes into account this latter possibility.	Higher intercept altitudes with both the interceptor and target on ascending trajectories do not create more debris, as the author indicates. The amount of debris produced is proportional to the closing velocity and the mass properties of each object (density, mass distribution) not the intercept conditions. MDA conducts a rigorous analysis to assess the risk to both manned and unmanned spacecraft prior to each mission. This analysis determines the safest time to conduct the flight test minimizing the probability of impact between intercept debris and spacecraft (including the ISS). The relatively small percentage of intercept debris (<10%) that remains orbital does not retain any semblance to a "cloud". It is important to understand that as a result of the high spreading velocities imparted to the debris post-intercept, the intercept debris spreads

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		Even if the debris remains in space only for a "few months" it would still pose a potential threat to space assets in its orbital pathway, including perhaps, as the PEIS itself admits, the International Space Station (ISS). While, as the PEIS notes, the ISS can be (and has been in the past) moved to avoid potential collision with space debris, this is not a simple task and takes time. Indeed, the PEIS couches its language on threats to the ISS by saying only that it "may be possible" for the ISS to perform collision avoidance to get out the way of any "large debris" created. Further, many other satellites in LEO lack the ability to maneuver at all to avoid debris - a fact that the PEIS fails to mention.	into the background, becomes a part of the background debris field - indistinguishable from background debris. With respect to the ISS, collision avoidance maneuvers would not be necessary. As per the current coordination with Air Force Space Command, safe launch times would be selected so that the debris cloud avoids the ISS altogether.
Orbital Debris	PHO0002-2	Space debris is a major hazard to spacecraft and satellites because of the high impact velocities generated in orbit, meaning that even tiny pieces of debris, which you mention, such as bolts can damage or destroy an on-orbit asset. Reentry of space-based objects, such as the SBIs, can also threaten people or objects on the ground, as not all debris is burned up on its way through the atmosphere.	Operational spacecraft are struck by small pieces of orbital debris and micrometeoroids routinely with little or no effect; many orbiting structures use shielding methods to protect from debris as large as 1 centimeter in diameter. The probability of two large objects colliding in space is very low, only one such documented incident has occurred between objects from different missions in 45 years.
Orbital Debris	PHO0002-5	Further, even short-term debris could be a danger to space objects such as the International Space Station, as the PEIS admits. And while the PEIS states that the ISS could be moved to avoid a collision with any large debris, it fails to recognize that other objects in low Earth orbit that might be threatened are not maneuverable.	See previous response.
Orbital Debris	PHW0003-4	Finally, the PEIS contradicts itself somewhat on the issue of debris risk by stating (on p. 4-132) that since the "debris created is expected to be small" and collision avoidance strategies could be used, there are "no	Because the development of a space-based test bed is too speculative to be analyzed in this PEIS, the specific impacts of launching interceptors from space-based platforms for BMDS testing would be considered in

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		significant impacts expected to the ISS." While it is debatable whether the debris would indeed be "small" - as the PEIS provides no actual modeling to predict the size of debris created by a ground-based midcourse intercept -the fact is that small debris could actually be more dangerous to the ISS and other spacecraft in LEO. That is because current debris tracking systems cannot track debris smaller than 10 centimeters in diameter (about the size of a softball) adequately enough to allow planning of collision avoidance maneuvers. Debris between 10 cm and 1 cm in diameter (a bit larger than a marble) will penetrate and damage most spacecraft (as the PEIS admits on p. 4-131) and could possible destroy space assets depending on where debris strikes the spacecraft. It also should be noted that the orbital plane between 300 and 400 kilometers is already one of the bands of space most polluted with this size of debris.	subsequent analyses as appropriate. The MDA wanted to consider the broad possibilities of space-based interceptors as an alternative strategy to enhance the integrated BMDS recognizing that the technologies for this application are in initial stages of planning and development and that subsequent NEPA analyses would likely be needed as technologies and plans became more mature.
Orbital Debris	PHO0002-11	Last of all, the PEIS also neglects a critical factor regarding the potential for debris creation from SBIs: that is, the fact that any architecture means large numbers of missiles filled with highly volatile rocket fuel would be orbiting in LEO at altitudes where they themselves will be constantly bombarded by space debris, with an attendant risk of explosion caused by debris impact.	See previous response.
Orbital Debris	PHW0003-5	The PEIS completely fails to support its claim that there would be no significant impact to spacecraft from the use of Space-Based Interceptors (SBIs) for either boost-phase intercept (as an ICBM is rising into the upper atmosphere) or midcourse intercept, due to the inability of the MDA to provide data required for necessary scientific review.	See previous response.

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		Given the inadequate articulation by MDA of the SBI concept and the lack of sufficient scientific coverage of space debris in this PEIS, it is impossible for the PEIS to make any claims about potential debris production from SBI tests, deployment or usage - other than that the creation of debris is a certitude. The PEIS states (p. 4-118), "Using interceptors from a space-based platform would create orbital debris, from successfully intercepting a threat missile and causing it to break up or from the break up of any unsuccessful interceptor or space platform." It further notes (p. 4-118) that SBIs would travel through space after launch, and thus potentially endanger other satellites it their path. It does not, however, mention the fact that launching an SBI constellation into either LEO or GEO would also have debris impacts that might be significant.	
Orbital Debris	PHW0003-6	The dangers of the debris created, however, can not be scientifically analyzed because the configuration of the SBIs themselves (i.e., their size, mass and speed) has yet to be revealed by MDA; neither has the architecture for their deployment (how many SBIs on orbit and at what altitude) or usage (how many SBIs would be fired at an incoming target) been publicly determined. As noted above, the potential for debris creation depends on a number of factors including the mass of the two objects, the speed of the impact, the altitude of the impact, and the angle of impact. With none of the specific parameters identified for a SBI system by MDA (including in this PEIS), these factors are impossible to model.	See previous response.
Orbital Debris	PHW0003-8	Third, and perhaps the most egregious inadequacy in the PEIS review of the SBI option, proposals for a SBI	See previous response.

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		network postulate between 500 and several thousand interceptors in LEO - each of which would be filled with a large amount of highly-volatile rocket fuel. Thus, the SBIs themselves would be in potential danger of colliding with space debris already on orbit. Such collisions could result in the explosion of the SBI. In fact, current orbital debris mitigation regulations in the United States and elsewhere, as a first-order priority, require space operators to vent any excess fuel from booster rockets used in launching satellites in order to avoid on-orbit explosions, which are proven to create vast amounts of wide-spread debris. The SBIs would also be constantly bombarded by smaller debris that could comprise their integrity. The PEIS completely ignores the possibility of SBIs being damaged by debris.	
Orbital Debris	PHW0003-9	And while the PEIS suggests the possibility that some SBIs also might be based in GEO, there is no effort to address the even more serious threats this architecture would pose to spacecraft. An SBI traveling toward the Earth from GEO would have many more opportunities to collide with other spacecraft as it passed through subsequently lower orbital altitudes. Also as GEO is already highly crowded with satellites (mostly for commercial communications and broadcast), the threat of debris creation by a network of new, explosive SBIs based in that orbital band could be high. Neither of these potential threats is modeled in the PEIS.	The BMDS PEIS states that space-based platforms for sensors or C2BMC could be placed into GEO; however, there is no mention of placing space-based platforms for weapons into GEO. If future plans were to identify the need for the use of space-based platforms for weapons in GEO, they would be considered in subsequent tiered analyses, as appropriate.
Orbital Debris	PHW0003-10	Indeed, the PEIS itself states (p. 4-116) that "additional environmental analysis could be needed as the technologies intended to be used became more defined and robust." Even more worrisome, an article in the Sept.	The MDA coordinates its activities with appropriate Federal agencies. The MDA participates in a Working Group studying the characterization of operational engagement space (i.e., conducting high speed, high

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		13 edition of Space News ("Space-Based Interceptor Could Pose Debris Threat") reveals that MDA has not even held detailed discussions about the potential for damaging debris from space-based interceptors with NASA's Orbital Debris Program Office.	altitude intercept scenarios to test GMD) with respect to debris risk. Members of the analysis working group include MDA, NASA, U.S. Air Force Space Command (AFSPC), the Aerospace Corporation, and System Test and Evaluation Planning Analysis Lab (STEPAL). The policy component of this working group includes NASA, AFSPC, STRATCOM, National Reconnaissance Office (NRO), and the Pacific Range Support Team (PRST). MDA is conducting modeling in this venue to try to consider realistic test scenarios and considering debris risk at the ground/surface and in space with the goal of developing criteria for protecting space assets. These efforts are currently underway.
Orbital Debris	PHW0003-11	The PEIS states on a number of occasions that any debris reentering the atmosphere from a midcourse intercept (by either ground-based or space-based interceptors) event would likely be "small" and thus "burn up" before impacting the ground. Considering that a Delta 2 second stage is a good bit smaller than either an ICBM or the current design of the ground-based midcourse interceptor, that statement is debatable. Nor is it supported by the PEIS itself, which simply does not provide the scientific analysis needed to determine the size of debris created by a midcourse intercept or the possibility of it making landfall intact	MDA has conducted an exhaustive study of the risks posed to spacecraft. Results are being coordinated with the space community. This analysis has shown that the majority of post-intercept debris resulting from high altitude intercepts would reenter the atmosphere within a few hours. A small amount of post-intercept debris may become orbital debris; however, risks to spacecraft from this debris are less than the risk posed by existing background debris. The MDA has created a technical appendix to the PEIS (see Appendix L), which provides additional information on the creation and reentry of orbital debris.
Orbital Debris	PHW0003-12	For example, in the case of a booster malfunction or a miss by an interceptor successfully launched from the ground, large pieces of debris likely would fall back to Earth. There is little evidence given in the PEIS to back its contrary assertion that debris would be small and limited in its "footprint." Even in the case of a successful	As part of the normal mission planning process, scenarios are designed so that in the event of a flight termination action, all debris will impact the open ocean or designated areas on land ranges. Booster drop zones, flight termination and intercept debris footprints are coordinated with the appropriate test range authorities.

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		intercept, there is no data provided by the PEIS about the likely size and altitude of debris, data that is required to predict whether or not pieces would make landfall intact.	
Orbital Debris	PHO0002-10	Number Two: The PEIS fails to support its claim that there would be no significant impact to spacecraft and satellites, and objects and people on the ground, from the testing and deployment of Space-Based Interceptors. Given the inadequate articulation by MDA of the SBI concept itself, it is impossible for the MDA to make any claims about the risks to space objects from SBIs. Debris creation depends on a number of specific factors about individual impacts, such as the mass of the two objects impacting, their relative velocities at impact, the angle of impact, and altitude. Since the MDA has yet to determine nor to provide in this PEIS critical design parameters of the SBIs themselves--their size, mass, and their speed--and the architecture of an SBI network, how many interceptors on orbit at what altitude--it is simply impossible for the MDA to support the PEIS claim that there is little debris risk, much less to support the PEIS suggestion that a space-based architecture would present less risk to the environment than a solely ground-based one. Without any specific parameters for an SBI network available, the MDA has no data for undertaking the necessary calculations to support its claims.	As stated in Section 4.2.1, during testing the MDA would select launch scenarios that would result in both the interceptor and intercept debris clouds impacting in designated areas within the ocean or on cleared land-based ranges. Because the development of a space-based test bed is too speculative to be analyzed in this PEIS at this time, further analysis would be conducted as the space-based technology develops and matures.
Orbital Debris	PHW0003-13	As the size, mass and speed of any SBI remains undetermined by MDA, it is impossible for the MDA at this time claim that there would be little risk of landfall by debris. However, the possibility of an SBI missing its	See previous response.

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		target and reentering the atmosphere is worrisome, and should be further reviewed using reentry modeling based on several SBI configuration options - modeling that has not been provided by the PEIS.	
Orbital Debris	PHW0003-14	The PEIS (p. 4-70) also states that "even if an object does survive reentry, only one third of the Earth's surface is land area, and only a small portion of this land area is densely populated. The chance of hitting a populated land area upon reentry would be small." While this is a statement of fact, it does not take into account the trajectory of likely missile tests or intercepts over the Earth. Where reentry might happen is dependent on from where the target missile is launched as well as from where the interceptor is launched, and at what point in their individual trajectories impact is made. The PEIS fails to provide specific data about likely intercept scenarios required to model possible reentry points. For example, there is some question about MDA's ability to do intercept tests from Ft. Greely, the first location for the new ground-based midcourse interceptors, because of concerns about endangering people and the environment. Finally, the PEIS itself admits (p. 4-122) that "Objects reentering may skip off the Earth's atmosphere, similar to a stone skipping across a pond, causing them to impact much farther away than originally predicted."	The PEIS is intended to provide a programmatic analysis of the potential impacts associated with the development, testing, deployment, and decommissioning of the BMDS. The PEIS is not a site- or component-specific environmental analysis and therefore does not provide specific information about particular components or their operation at various facilities. Specific booster or debris impact zones are coordinated with the appropriate test range authority months if not years prior to a mission. Moreover, coordination is conducted for every mission. If future plans identify specific locations that are required to support specific target and interceptor launches, they would be considered in subsequent tiered NEPA analyses, as appropriate.
Orbital Debris	PHW0003-15	In the case of a SBI launch designed to hit an ICBM in its boost phase, it is currently (as with a midcourse design) impossible to predict with reliability the potential for debris to make landfall intact due to the lack of data about the configuration of SBIs. That said, however, a miss likely would result in major ground impact. That is	There is no reason to believe that if there is a miss during a future test involving a space-based interceptor that there would be major impact on the ground. Although it is completely speculative at this point, a space-based interceptor intended for use as a test article would likely be fitted with a flight termination system to preclude an

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		because by any design, an SBI must be able to survive reentry of the atmosphere so as to hit the target ICBM before it exits the atmosphere. This issue is not addressed by the PEIS at all - and represents a fact that seems to run directly counter to the PEIS's assertion (p. 4-121) that, "Upon reentry, the majority of the space-based interceptor and its platform would burn due to the intense friction and heat created during reentry through the Earth's atmosphere."	intact interceptor from reaching the surface of the Earth. Further, a missed intercept would likely bounce off the atmosphere and spin out into space. The altitude and trajectory for space-based boost phase intercepts have not yet been determined; however, the space platform (vehicle) itself would likely leave its parking orbit upon communication that a boost phase engagement was to occur, it would likely deploy one or more kill vehicles (multiple mini-kill vehicles) that would serve as the boost phase interceptors, and the space platform would then return to its parking orbit.
Orbital Debris	PHW0003-16	Finally, the PEIS admits that any accident (such as a communications failure caused by a defect or jamming) that caused an SBI to reenter the Earth's atmosphere in an uncontrolled manner could create a danger to aircraft in flight. It states (p. 4-121), "Given the difficulty in predicting that path of uncontrolled reentering space-based interceptors and their associated platforms, little advanced warning could be given to clear airspace." It then goes on to assert that most objects break up upon reentry and the impacts to airspace would not likely be significant - an assertion for which no scientific backup is provided, especially given the fact that SBIs designed for boost-phase intercept would by their nature be required to reenter at least the upper atmosphere intact. Further, even smaller pieces of white-hot debris could severely damage an aircraft in flight.	Assuming a space platform with kill vehicles awaits communication of a boost phase engagement, it would come out of parking orbit and deploy one or more kill vehicles that would serve to intercept the target, and then return to orbit. The technologies for space-based interceptors are simply not mature enough to state for certain whether they would break up, burn up or reenter intact given their intended use especially as test articles. However, testing involving space-based boost phase intercepts would always take place in restricted airspace after ensuring that NOTAMs have been issued and the airspace has been cleared prior to test activities. It is extremely unlikely that a test scenario would result in danger to aircraft because the scheduling and safety restrictions prior to and during testing are stringent and are rigorously applied to ensure that this type of accident does not happen.
Orbital Debris	PHO0002-7	That said, the PEIS does not provide adequate scientific review to support the assertion that most debris would be small, a term that is undefined in the PEIS, raising the	The MDA has created a technical appendix to the PEIS (see Appendix L), which provides additional information on the creation, reentry, and disposition of orbital debris.

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		question of the risks from reentry into the atmosphere of both the interceptor and its target after an impact.	
Orbital Debris	PHO0002-8	Not all debris reentering the atmosphere burns up, as the PEIS suggests.	See previous response.
Orbital Debris	PHO0002-9	In January 1997, a Delta Two rocket second stage came down over Georgetown, Texas, with large pieces making landfall including a 580-pound stainless-steel fuel tank that landed 50 yards from a house. Another Delta Two second stage reentered the atmosphere over Cape Town, South Africa in April 2000, similarly raining large pieces of debris to the ground. It is important to note that a Delta Two second stage is considerably smaller than the either a ground-based midcourse interceptor or a target ICBM. It also is highly difficult to predict reentry trajectories even from scripted test events because debris can, as the PEIS admits, skip off the atmosphere and land miles away from its original reentry point, and the PEIS provides no evidence that MDA made any significant effort to undertake the complex computer modeling required to predict such possible reentry scenarios.	The MDA has performed modeling of high altitude ground-based intercepts. This modeling has shown that the majority of post-intercept debris resulting from high altitude intercepts would reenter the atmosphere within a few hours. A small amount of post-intercept debris may become orbital debris; however, risk to spacecraft from this debris is less than the risk posed by existing background debris. The MDA has added a technical appendix to the PEIS (see Appendix L), which provides additional information on the creation and reentry of orbital debris.
Orbital Debris	PHO0002-12	The PEIS ignores this risk altogether. In sum, the PEIS fails to support its conclusions about the risk from the creation of orbital debris and its possible reentry into the atmosphere due to a lack of adequate and complete scientific review.	See previous response.
Perchlorate	E0319-24	The PEIS should include any environmental health hazard studies the Department of Defense (DOD) has done since 1997 on children living in communities near rocket/missile launch sites and/or U.S. military training bases world-wide. An excerpt from an October 1, 2004 DOD news release titled: 'DOD, California Perchlorate	Section 4.1.1.2 of the Draft PEIS provided information developed by the Perchlorate Study Group, this group worked with the U.S. EPA, NASA, state governments, water purveyors, and other business organizations to assess whether there is a level of perchlorate in drinking water that poses a risk to human health. In addition to

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		Sampling Prioritization Protocol Reached', stated: "Currently, no drinking water standard for perchlorate has been adopted". According to the news article, the DOD apparently is finally agreeing to involve itself with environmental studies, along with the state of California, to research the findings of large quantities of perchlorates in the state's drinking water. Since perchlorate is a rocket and missile propellant, and there have been no previous drinking water standards for the chemical, the PEIS cannot state without conclusive studies that there has been no health and safety risks to children (or the general public) who live near test launch sites.	citing the Perchlorate Study Group findings, the Final PEIS has been modified to include the proposed findings from the State of California Office of Environmental Health Hazard Assessment, the State of Massachusetts, and U.S. EPA. The U.S. EPA has established an official reference dose (RfD) of 0.0007 milligrams per kilogram (mg/kg) per day of perchlorate, which translates into a drinking water equivalent level of 24.5 parts per billion (ppb). A Drinking Water Equivalent Level, which assumes that all of a contaminant comes from drinking water, is the concentration of a contaminant in drinking water that will have no adverse effect with a margin of safety. Because there is a margin of safety built into the RfD and the drinking water equivalent level, exposures above the drinking water equivalent level are not necessarily considered unsafe. To better characterize some of the potential impacts associated with proposed BMDS activities, additional information and research on perchlorate has been added to Section 4.1.1.2 of the Final PEIS. Further, a technical appendix (see Appendix M) addressing issues specifically related to perchlorate has been added to the Final PEIS.
Perchlorate	E0326-1	The testing of the system at Vandenberg AFB has inevitably had the effect of polluting the surrounding area with perchlorates. We do not know the extent of birth defects and growth retardation caused by rocket fuel in	The DoD and the MDA are aware of the potential health concerns associated with perchlorate contamination. The DoD, U.S. EPA, DOE, and NASA asked the National Research Council (NRC) to assess independently the adverse health effects of perchlorate ingestion from

Issue Topic	Comment Number	Excerpt Text	Response
		this area because no studies among this population have been done.	clinical, toxicological, and public health perspectives. The NRC study considered thyroid function in infants including possible impacts from perchlorate exposure on birth defects and skeletal growth. Regarding birth defects resulting from non-normal thyroid function the NRC study states: *"The consequences of severe combined maternal and fetal hypothyroidism during fetal life and in newborn infants include microcephaly (small brain), mental retardation, deaf-mutism, paraplegia or quadriplegia, and movement disorders. Those abnormalities are not reversible by treatment with T4 (Foley 2000). However, the abnormalities can be largely prevented by administration of iodide to the mothers before or during the first trimester and early part of the second trimester of pregnancy (Pharoah 1993; Cao et al. 1994)."* Regarding impacts to skeletal growth from non-normal thyroid function, the NRC study states: *"T4 and T3 also are required for normal skeletal development and growth. Bone cells have T3 receptors, and T3 stimulates bone formation and the appearance of the epiphyseal centers that are needed for normal growth of long bones. T3 also stimulates the production of pituitary growth hormone and insulin-like growth factor. Treatment with T4 leads to resumption of bone growth and*

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
			skeletal maturation, but severely affected infants are unlikely to have normal stature." In addition, the NRC report noted that "The primary sources of uncertainty in estimating an RfD for perchlorate in drinking water arise from the absence of data on possible side effects of iodide deficiency (pregnant women and their fetuses and newborns). Therefore, new epidemiologic research should assess the possible health effects of perchlorate exposure in those populations." Section 4.1.1.2 of the Draft PEIS provided information developed by the Perchlorate Study Group, this group worked with the U.S. EPA, NASA, state governments, water purveyors, and other business organizations to assess whether there is a level of perchlorate in drinking water that poses a risk to human health. The Final PEIS has been modified to include the proposed findings from the State of California Office of Environmental Health Hazard Assessment, the State of Massachusetts, and U.S. EPA. To better characterize some of the potential impacts associated with proposed BMDS activities, additional information and research on perchlorate has been added to Section 4.1.1.2 of the Final PEIS. Further, a technical appendix (see Appendix M) addressing issues specifically related to perchlorate has been added to the Final PEIS. The appendix considers the uses, sources, and disposal of perchlorate as well as the effects on human health and the

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
			environment. It should be noted that future tiered analyses for specific proposed activities at sites such as Vandenberg AFB would appropriately consider the potential impacts of activities on water quality.
Perchlorate	E0363-1	In particular, I am concerned about the hazardous waste associated with the system. For example, perchlorate from rocket fuel has already contaminated rivers and ground water, and can find its way into milk supplies (e.g., as has occurred in Texas). Like other toxins that act as endocrine disruptors, perchlorate can interfere with thyroid hormones and disrupt pre- and post-natal brain development, resulting in reductions of IQ and attention, mental retardation, hearing loss, and defects in speech and coordination. Seventeen percent of children suffer from developmental and learning disabilities, and as many as 25% of those disabilities are due to the effects of environmental toxins either acting alone or in combination with genetic and other environmental factors.	The DoD and the MDA are aware of the potential health concerns associated with perchlorate contaminated water. However, currently, there are no Federal drinking water standards for perchlorate. The U.S. EPA would be responsible for establishing Federal drinking water standards and has issued draft risk assessments of perchlorate. However, these assessments have been criticized because it has been suggested that the findings are based on flawed scientific studies and that not all available data were considered and incorporated into the assessments. The U.S. EPA study's draft RfD for perchlorate was 0.00003 mg/kg per day and the NRC study recommended an RfD of 0.0007 mg/kg per day. The NRC stated that this value is supported by other clinical studies, epidemiologic studies, and studies of long-term perchlorate administration. The NRC report concluded that the proposed RfD of 0.0007 mg/kg per day should protect even the most sensitive populations. The U.S. EPA has established an official RfD of 0.0007 mg/kg per day of perchlorate, which translates into a drinking water equivalent level of 24.5 ppb. A Drinking Water Equivalent Level, which assumes that all of a contaminant comes from drinking water, is the concentration of a contaminant in drinking water that will have no adverse effect with a margin of safety. Because there is a margin of safety built into the RfD and the drinking water equivalent level, exposures above

			the drinking water equivalent level are not necessarily considered unsafe. To better characterize some of the potential impacts associated with proposed BMDS activities, additional information and research on perchlorate has been added to Section 4.1.1.2 of the Final PEIS. Further, a technical Appendix M addressing issues specifically related to perchlorate has been added to the Final PEIS.
Perchlorate	PHO0025-1	This weapons system is designed to intercept enemy missiles in space from ground platforms in Fort Greely, Alaska, Vandenberg Air Force Base in Southern California. The chemicals used in solid rocket propellant that would be used to launch the intercept missiles, the test missiles and especially the booster rockets that place related detection communication satellites in space would all use imodium perchlorates as the oxidizing agent in the rocket fuel. The fuel would also contain highly toxic hydrazine compounds and nitrogen oxide. In the news of late, the developmental toxin perchlorate has been found in many of our nation's drinking water sources. This chemical inhibits thyroid hormone creation and release. In low doses, perchlorate is presumed to decrease the intelligence potential of a developing fetus. In cases of more severe exposure, can cause frank retardation. Additionally, once combusted and exposed to air moisture, perchlorates create hydrochloric acid, more commonly known as "acid rain."	The DoD and the MDA are aware of the potential health concerns associated with perchlorate contaminated water. In 1985, perchlorate was detected in wells of California Superfund sites; however, perchlorate contamination was not detected nationwide until 1997. Currently, there are no Federal drinking water standards for perchlorate. The DoD, U.S. EPA, DOE, and NASA asked the NRC to assess independently the adverse health effects of perchlorate ingestion from clinical, toxicological, and public health perspectives. The NRC report considered the potential health effects to children born to mothers with non-normal thyroid function and found that *"Those studies, although not definitive, suggest an effect on development in infants whose mothers had subclinical hypothyroidism or low-normal serum free T4 concentrations during pregnancy, but they have limitations. The differences in test scores were small, and the scores could be confounded by socioeconomic, educational, and other differences*

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
			between the study groups. Moreover, the results contrast with the normal development of the infants of mothers who had overt hypothyroidism (Liu et al. 1994). Nonetheless, if confirmed, they emphasize the potential vulnerability of fetuses to decreases in maternal thyroid function." A technical appendix (see Appendix M) addressing issues specifically related to perchlorate has been added to the Final PEIS. Section 4.1.1.2 of the Final PEIS considers the impacts of exhaust products from solid propellant boosters; including the impact from the conversion of hydrogen chloride to hydrochloric acid.
Perchlorate	E0376-1	In the draft Programmatic Environmental Impact Statement for the Missile Defense System (1 September 2004), I would like to point out incomplete and misleading statements about perchlorate toxicity and standards in the bottom paragraph on Vol. 1, p. 4-56. This discussion provides the viewpoint of the DoD and the Perchlorate Study Group, an Industry Workgroup, on perchlorate toxicity, but ignores all risk assessments conducted by actual risk assessment agencies. The U.S. EPA has been evaluating perchlorate toxicity for years, in association with several defense agencies (as stated), and has released a draft risk assessment which proposes a drinking water equivalent level of 1 ppb. The State of California Office of Environmental Health Hazard Assessment has published our risk assessment	In addition to citing the Perchlorate Study Group findings, the Final PEIS has been modified to include the proposed findings from the State of California Office of Environmental Health Hazard Assessment, the State of Massachusetts, and U.S. EPA. To better characterize some of the potential impacts associated with proposed BMDS activities, additional information and research on perchlorate has been added to Section 4.1.1.2 of the Final PEIS. Further, a technical appendix (see Appendix M) addressing issues specifically related to perchlorate has been added to the Final PEIS. The appendix considers the uses, sources, and disposal of perchlorate as well as the effects on human health and the environment.

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		which estimates a health-protectice level of perchlorate in drinking water of 6 ppb. The State of Massachusetts has recently released their evaluation with a recommended drinking water level of 1 ppb to protect pregnant women and fetuses (or other sensitive sub-populations), and 18 ppb for healthy adults. The U.S. EPA guidance applicable to water contaminant plumes emanating from industrial and DoD sites has used a standard of 4-18 ppb for several years. To not consider and apply these relevant and applicable standards to the evaluation of potential environmental impact of the deployed missile systems seems to me to be putting both the DoD and the public at risk, both from legal liability and potential chemical hazards. I recommend that this section of the report, and any financial and toxicological calculations based on it, be revised to include the viewpoints expressed by the regulatory agencies whose job it is to regulate the public and environmental exposure to perchlorate. Acknowledging these opinions need not wait for the finalization of the U.S. EPA's current draft risk assessment for perchlorate, currently under review by the National Academy of Sciences, nor the promulgation of the California Maximum Contaminant Level for perchlorate in drinking water, scheduled for 2005.	
Perchlorate	E0427-7 and E0439-7	8) Ammonium perchlorate is one of the main components of rocket fuel, typically constituting 60% to 75% of missile propellant and about 70% of space shuttle rocket motors. Since the fuel and perchlorate goes flat, the fuel/perchlorate has to be replaced every few years or it	Section 4.1.1.2 of the Draft PEIS provided information developed by the Perchlorate Study Group, this group worked with the U.S. EPA, NASA, state governments, water purveyors, and other business organizations to assess whether there is a level of perchlorate in drinking

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		will fail to function properly, thereby increasing the amount of perchlorate waste and exposure problems. Ammonium Perchlorate is well characterized as a thyroid hormone disruptor. http://www.ewg.org/reports/rocketscience/chap3.html. At high enough concentrations, perchlorate can affect thyroid gland functions, where it blocks iodide uptake necessary for the synthesis of thyroid hormones (Urbansky 2002). Perchlorate can cause hypothyroidism, and thyroid cancer. The environmental levels of perchlorate have been show to inhibit development in frogs (Goleman et al. 2002). California has extensive perchlorate contamination problems with the drinking water sources of at least 7 million Californians and millions of other Americans are contaminated with perchlorate. A federal safe daily perchlorate exposure has not yet been set by the EPA, and its expected release in 2002 has been delayed. It has been delayed since the DoD objected to EPA studies suggested a standard of 1 ppb. Senator Barbara Boxer has introduced legislation to require the EPA to establish a standard for perchlorate contamination by July 1, 2004. While most contaminated samples are in the 4 to 20 ppb levels, surveys of California water sources show several sites with perchlorate levels from 4 to 820 ppb. http://www.ewg.org/reports/rocketwater/tablel.php Ammonium perchlorate used in solid propellants blocks the formation of key thyroid hormones which are critical for growth and development especially in fetuses and children. The PEIS proposes to allow over 30-fold higher levels of perchlorate (200 parts per billion) than that proposed by the State of California (6 parts per billion).	water that poses a risk to human health. In addition to citing the Perchlorate Study Group findings, the Final PEIS has been modified to include the proposed findings from the State of California Office of Environmental Health Hazard Assessment, the State of Massachusetts, and U.S. EPA. Currently, there are no Federal drinking water standards for perchlorate. The U.S. EPA would be responsible for establishing Federal drinking water standards and has issued draft risk assessments of perchlorate. However, these assessments have been criticized because it has been suggested that the findings are based on flawed scientific studies and that not all available data were considered and incorporated into the assessments. The U.S. EPA study's draft RfD for perchlorate was 0.00003 mg/kg per day and the NRC study recommended an RfD of 0.0007 mg/kg per day. The NRC stated that this value is supported by other clinical studies, epidemiologic studies, and studies of long-term perchlorate administration. The NRC report concluded that the proposed RfD of 0.0007 mg/kg per day should protect even the most sensitive populations. The U.S. EPA has established an official RfD of 0.0007 mg/kg per day of perchlorate, which translates into a drinking water equivalent level of 24.5 ppb. A Drinking Water Equivalent Level, which assumes that all of a contaminant comes from drinking water, is the concentration of a contaminant in drinking water that will have no adverse effect with a margin of safety. Because there is a margin of safety built into the RfD

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		As pointed out in the comments of Lenny Siegel: The reason that there is no federal drinking water standard for perchlorate is that the Defense Department objected to EPA studies that suggested a standard of one part per billion (ppb). Meanwhile, regulatory agencies are using levels far below the 200 ppb asserted in the PEIS. On the way to establishing its own legal standard, California has adopted a Public Health Goal of 6 ppb (Frequently Asked Questions (FAQs) About the Public Health Goal for Perchlorate," California Office of Environmental Health Hazard Assessment (OEHHA), March 11, 2004. hittp:/www.oehha.ca.gov/public_info/facts/perchloratesfac ts.html). Even these levels of perchlorate may be detrimental to fetuses and infants. The human study considered in setting the California public health goal did not evaluate pregnant women, fetuses or infants (Greer et al. 2002). The study of Greer at al 2002, only used a 14-day exposure to perchlorate, which is insufficient to deplete thyroid colloid which acts as a storage form of thyroid hormones. Thus this study is insufficient to estimate the effect of long-term perchlorate exposure on iodine uptake or thyroid hormone levels. Since the effect of long term perchlorate exposure on reducing thyroid hormone levels, especially in the fetus and in infants has not been considered, the MDA needs to evaluate these effects on these sensitive groups as required by federal law. In May, 2004, Massachusetts identified a reference dose for perchlorate that would correspond to a 1 ppb drinking water exposure limit. Also note that perchlorate	and the drinking water equivalent level, exposures above the drinking water equivalent level are not necessarily considered unsafe. To better characterize some of the potential impacts associated with proposed BMDS activities, additional information and research on perchlorate has been added to Section 4.1.1.2 of the Final PEIS. Further, a technical appendix (see Appendix M) addressing issues specifically related to perchlorate has been added to the Final PEIS.

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		is found in milk and in several plant species, including lettuce, where high levels have been reported. Thus multiple sources of perchlorate exposure need to be considered.	
Perchlorate	E0427-8 and EO439-8	9) To ensure maximum environmental protection and reduce known, widespread human health risks from the use and disposal of rocket propellants, the BMDS PEIS should compare the proposed alternatives against a real No Action Alternative. At a minimum the BMDS PEIS should: A. Acknowledge and address emerging regulatory standards for perchlorate exposure. B. Consider the effects of perchlorate on susceptible subpopulations, including fetuses, and children. The MDA also needs to consider the effects of perchlorate exposure on even more sensitive congenitally hypothyroid populations, so that these individuals are not detrimentally affected by perchlorate from BMDS missile launches. C. Since water supplies in several regions of central and southern California are already at, exceeding and in some cases markedly exceeding the emerging regulatory standards for perchlorate, the MDA should acknowledge and address the perchlorate problem so as to protect the public.	The DoD and the MDA are aware of the potential health concerns associated with perchlorate contaminated water. In 1985, perchlorate was detected in wells of California Superfund sites; however, perchlorate contamination was not detected nationwide until 1997. Currently, there are no Federal drinking water standards for perchlorate. The U.S. EPA would be responsible for establishing Federal drinking water standards and has issued draft risk assessments of perchlorate. However, these assessments have been criticized because it has been suggested that the findings are based on flawed scientific studies and that not all available data were considered and incorporated into the assessment. The U.S. EPA study's draft RfD for perchlorate was 0.00003 mg/kg per day and the NRC study recommended an RfD of 0.0007 mg/kg per day. The NRC stated that this value is supported by other clinical studies, epidemiologic studies, and studies of long-term perchlorate administration. The NRC report concluded that the proposed RfD of 0.0007 mg/kg per day should protect even the most sensitive populations. The U.S. EPA has established an official RfD of 0.0007 mg/kg per day of perchlorate, which translates into a drinking water equivalent level of 24.5 ppb. A Drinking Water Equivalent Level, which assumes that all of a contaminant comes from drinking water, is the concentration of a contaminant in drinking water that

			will have no adverse effect with a margin of safety. Because there is a margin of safety built into the RfD and the drinking water equivalent level, exposures above the drinking water equivalent level are not necessarily considered unsafe. The NRC report noted that "The primary sources of uncertainty in estimating an RfD for perchlorate in drinking water arise from the absence of data on possible side effects of iodide deficiency (pregnant women and their fetuses and newborns). Therefore, new epidemiologic research should assess the possible health effects of perchlorate exposure in those populations." The Council's report further stressed that "Finally, in its deliberations on the health effects of perchlorate in drinking water, the committee considered pregnant women and their fetuses to be particularly sensitive populations." Epidemiologic studies considered by the NRC have examined the relationship between perchlorate exposure and thyroid function and thyroid disease in newborns, children, and adults. The NRC concluded that no studies have investigated the effect of perchlorate exposure in vulnerable groups, such as low-birth weight or preterm infants. In addition, these studies have not considered the impacts to the offspring of mothers who were exposed to perchlorate and had a low iodide intake. Finally, adequate studies have not been completed of maternal perchlorate exposure and neurodevelopment outcomes in infants.

		facilities such as Cape Canaveral and Vandenberg Air Force Base.	BMDS activities would be conducted in compliance with all applicable regulations regarding perchlorate.
Perchlorate	F0005-12	The PEIS should provide more detailed estimates of perchlorate waste likely to be generated by system development, testing, deployment, maintenance, and decommissioning, and acknowledge the potential impacts of such exposure.	This PEIS is not intended to analyze specific testing or deployment of defined missile defense architecture. Therefore, it is not possible to provide detailed estimates of perchlorate likely to be generated by BMDS-related activities. The MDA has stated that disposal of hazardous materials and hazardous wastes will be conducted in compliance with applicable regulations. The DoD and the MDA are aware of the potential health concerns associated with perchlorate contaminated water. To better characterize some of the potential impacts associated with proposed BMDS activities, additional information and research on perchlorate has been added to Section 4.1.1.2 of the Final PEIS. Further, a technical appendix (see Appendix M) addressing issues specifically related to perchlorate has been added to the Final PEIS. The appendix considers the uses, sources, and disposal of perchlorate as well as the effects on human health and the environment.
Propellant	E0402-6	3) Rocket launches result in incredible amounts of chemical releases. Liquid propellants containing hydrazines, nitrogen tetraoxide, and other compounds are highly toxic to all living species. Ammonium perchlorate used in solid propellants blocks the formation of key thyroid hormones which are critical for growth and development especially in fetuses and children. The PEIS proposes to allow over 30-fold higher levels of perchlorate (200 parts per billion) than that proposed by the State of California (6 parts per billion).	The environmental impacts from the use of various liquid and solid propellants are discussed in Section 4.1.1.2 of the PEIS. This section of the Final PEIS has been modified to include additional information regarding the potential impacts of perchlorate. Further, a technical appendix (see Appendix M) addressing issues specifically related to perchlorate has been added to the Final PEIS. The appendix considers

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
			the uses, sources, and disposal of perchlorate as well as the effects on human health and the environment.
Propellant	E0427-6, E0439-6	7) Liquid propellants containing hydrazines, nitrogen tetroxide, and other compounds are highly toxic. At very low concentrations, hydrazines irreversibly cross link to aldehyde groups on proteins at slightly acidic pH and can cause cancer. One of the most concerning pollutants from the firing of rocket engines is HC1, which combines with atmospheric water to produce acid rain. The PEIS did not address potential for interactions between HC1 and hydrazines commonly used in rocket engines such as monomethylhydrazine (MMH) and Unsymmetric dimethylhydrazine (UDMH). Specifically does the toxicity of hydrazine increase under acidic conditions found in acidic rocket exhaust?	Hydrazine and nitrogen tetroxide are hypergolic propellants and when used to power a rocket are not emitted in the rocket motor exhaust - they react without initiation to provide thrust to a rocket motor, resulting in emissions that include carbon monoxide, carbon dioxide, water, nitrogen, hydrogen, and nitrogen oxides. Hydrazine fuels are very reactive reducing agents that are hygroscopic and will react with carbon dioxide and oxygen in the air. However, hypergolic propellant systems do not generate hydrogen chloride, and thus would have no opportunity to interact with hydrogen chloride in the emission exhaust environment.
Propellant	E0429-4 and PHW0004-4	Perchlorate, primarily from the manufacturing, testing, aborted launches, maintenance, and decommissioning of solid rocket motors, is polluting the drinking water of more than twenty million people and may be endangering natural ecosystems from Cape Canaveral to the Marshall Islands. The PEIS understates the risks of exposure, and it fails to provide data on the quantities of solid rocket propellant likely to be produced, used, released, and disposed by the BMDS. The PEIS should consider the environmental consequences of various disposal strategies so the BMDS program can develop the technology or capacity to address its waste or consider the use of alternative launch technologies or strategies to minimize either the waste or the negative environmental impacts.	Section 2.1.3.2 of the BMDS PEIS describes the spiral development process which will be used to determine which components will be transitioned to the military service responsible for deployment, operation and maintenance. The PEIS does not attempt to detail the architecture of the deployed BMDS. The PEIS states "Thus the MDA can consider deployment of a missile defense system that has no specified final architecture and no set operational requirements but which will be improved incrementally over time." Therefore, it cannot be said with certainty how much propellant will be used or how often it will be necessary to dispose of propellant. A technical appendix (see Appendix M) addressing issues specifically related to perchlorate has been added to the Final PEIS. The appendix considers the uses,

Exhibit K-3. Responses to Comments – Environmental Impacts

			sources, and disposal of perchlorate as well as the effects on human health and the environment. The BMDS PEIS considers the use of a wide variety of propellants including three types of boosters, pre-fueled liquid propellant, non-pre-fueled liquid propellant, and solid propellant boosters. The environmental impacts of the use of each of these three types of boosters are presented in Section 4.1.1.2 of the PEIS. In addition, DoD-wide research initiatives under the Strategic Environmental Research and Development Program have focused on the development of more environmentally-friendly launch technologies, such as missile propellants that do not use ammonium perchlorate as an oxidizer. While these alternate propellant formulations have shown promise, a significant amount of development remains to optimize the formulation for specific missile systems. In addition, these formulations will go through a lengthy and stringent performance and safety certification process. Because these alternative technologies are in a research and development phase and, are not yet advanced enough for their use to be reasonably foreseeable under NEPA, they are not analyzed in this PEIS. The MDA may consider the use of these alternative environmentally-friendly technologies as they become available in the future and meet the operational test requirements for the BMDS. Among launch technologies that are available today, the BMDS PEIS considers a wide variety of propellants used in three types of boosters, pre-fueled liquid propellant, non-pre-

Exhibit K-3. Responses to Comments – Environmental Impacts

			fueled liquid propellant, and solid propellant boosters. The environmental impacts of each of these three types of boosters are presented in Section 4.1.1.2 of the PEIS. Additional information on perchlorate has been added to the PEIS text as well as a technical Appendix M on perchlorate. This appendix considers the uses, sources, and disposal of perchlorate as well as the human health and ecological risk of exposure to perchlorate.
Propellant	E0429-9 and PHW0004-9	However, liquid propellants, such as the hypergolic propellant containing hydrazine compounds and nitrogen tetroxide, are highly toxic, and the PEIS should consider how to minimize their environmental, health, and safety impacts as well.	See previous response.
Propellant	E0429-12 and PHW0004-12	The PEIS suggests that aluminum oxide, the other major combustion product of solid propellant, is non-toxic. (page 4-60) However, there is some evidence that aluminum in acid environments is toxic to fish. [Footnote 1: See, for example, Baker& Schofield, "Aluminum Toxicity to Fish in Acidic Waters," Water, Air, and Soil Pollution, 1987, cited in Heinz J. Mueller, Chief, Environmental Policy Section, Federal Activities Branch, U.S. EPA Region 4, "Environmental Assessment (EA) and Finding for No Significant Impact (FONSI) fro the Proposed Titan IV Upgrade Program. Cape Canaveral Air Force Station (CCAFS) and Kennedy Space Center (KSC), FL," letter to Captain Anothonly E. Fontana, III, Environmental Planning Division, Regional Civil Engineer, Eastern Region, Department of the Air Force, March 28, 1990.] The PEIS should review the literature and reconsider its conclusion based upon the weight of evidence.	MDA conducted a literature review for technical issues in this PEIS including the toxicity of Al_2O_3 which comprises the particulate matter in SRM emissions. The article indicated by the commenter refers to the increase in toxicity to fish of aluminum (as Al+3 ions) in acid waters (i.e., pH of 5 or less). Aluminum occurs naturally in soils/rock in such abundance that the amount of aluminum introduced into the atmosphere from Al_2O_3 emissions from the combustion of SRMs would be insignificant. Al_2O_3 also is naturally occurring in the environment and is used as an abrasive and polishing agent and is sold by many chemical supply companies. It is non-toxic, non-reactive and is not listed as a chemical of concern by the U.S. EPA or any Federal agency regulating toxic substances. Al_2O_3 is not toxic to humans or ecosystems. Al_2O_3 emissions might be of concern from a visibility perspective on the ground and

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
			they have been studied as potential reaction sites in the stratosphere participating in the production of ozone. Neither has been determined to be significant impacts from BMDS launches.
Propellant	E0429-15 and PHW0004-15	Similarly, with the release of ozone-depleting compounds to the atmosphere, we as a society might decide that we shouldn't abruptly end space launches that depend upon solid rocket propellant. Instead, we might set a goal for the deployment of alternatively fueled rockets. The PEIS considers no such goal, despite the urgent need to mitigate global ozone depletion.	The PEIS did not conclude that launches related to BMDS activities would lead to significant impacts on global ozone depletion. Please refer to Section 4.1.1.2 of the PEIS for additional information on the potential impacts to the atmosphere of BMDS related launches. The BMDS PEIS considers the use of a wide variety of propellants including three types of boosters: pre-fueled liquid propellant, non-pre-fueled liquid propellant, and solid propellant. As new technologies and propellants are developed and found to meet the needs of supporting the BMDS they could be incorporated into the BMDS.
Propellant	E0429-16 and PHW0004-16	The Defense Department, NASA, and others have conducted research on propellants designed to achieve the thrust of ammonium-perchlorate-based fuels without the environmental hazards, but these efforts are poorly funded, and there appears to be no urgency. The BMDS program should at the very least, in its PEIS, evaluate the mitigation of seriously harmful environmental consequences through the development and deployment of alternative solid rocket propellants.	The BMDS PEIS considers the use of a wide variety of propellants including three types of boosters, pre-fueled liquid propellant, non-pre-fueled liquid propellant, and solid propellant boosters. The environmental impacts of each of these three types of boosters are presented in Section 4.1.1.2 of the PEIS. In addition, Appendix M includes DoD-wide research initiatives under the Strategic Environmental Research and Development Program that have focused on the development of more environmentally-friendly launch technologies, such as missile propellants that do not use ammonium perchlorate as an oxidizer. While these alternate propellant formulations have showed promise, a significant amount of development remains to optimize the formulation for specific missile systems. In addition, these formulations will go through a lengthy and

			stringent performance and safety certification process. Since these alternative technologies are in a research and development phase and are not yet advanced enough for their use to be reasonably foreseeable under NEPA, they are not analyzed in this PEIS. The MDA may consider the use of these alternative environmentally-friendly technologies as they become available in the future and meet the operational test requirements for the BMDS. Among launch technologies that are available today, the BMDS PEIS considers a wide variety of propellants used in three types of boosters, pre-fueled liquid propellant, non-pre-fueled liquid propellant, and solid propellant boosters. The environmental impacts of each of these three types of boosters are presented in Section 4.1.1.2 of the PEIS.
Propellant	E0429-17 and PHW0004-17	Rocket fuel wastes, from manufacturing, testing, training, maintenance, and decommissioning are a significant environmental hazard. This is a front page news story from California to Massachusetts, but it is barely mentioned in the PEIS.	To better characterize some of the potential impacts associated with proposed BMDS activities, additional information on perchlorate has been added to Section 4.1.1.2 of the Final PEIS. Further, a technical appendix (see Appendix M) addressing issues specifically related to perchlorate has been added to the Final PEIS. The appendix considers the uses, sources, and disposal of perchlorate as well as the effects on human health and the environment.
Propellant	E0429-18, PHW0004-18	The PEIS should offer estimates of the quantities of solid rocket fuel that will be manufactured for the BMDS, not just for testing, but for missiles that will be deployed and hopefully never be launched. From that figure, it can estimate the quantities of manufacturing waste- propellant takes, chips, and wastewater-likely to be generated. The PEIS estimates that the BMDS program will launch 413	Section 2.1.3.2 of the BMDS PEIS describes the spiral development process which will be used to determine which components will be transitioned to the military service responsible for deployment, operation and maintenance. The PEIS does not attempt to detail the architecture of the deployed BMDS. The PEIS states "Thus the MDA can consider deployment of a missile

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		solid-propellant rockets, containing from under 500 kilograms (1,102 pounds) to 60,000 kilograms (132,277 pounds) of solid propellant each. About 70% of that propellant, by weight, will consist of ammonium perchlorate. But nowhere does it estimate what quantity of propellant will be contained in deployed missiles, or even how many missiles will be part of that system. Without that information there is no way to project the amount of propellant waste likely to be generated by the program.	defense system that has no specified final architecture and no set operational requirements but which will be improved incrementally over time." Therefore, it cannot be said with certainty how much propellant will be used or how often it will be necessary to dispose of propellant.
Propellant	E0429-19, PHW0004-19	Yet the PEIS appears not to address the environmental aspects of missile maintenance and it gives only cursory mention to decommissioning: Decommissioning of missiles would first require the removal and proper disposal of liquid, solid, or hybrid (liquid and solid combination) propellants from the booster(s). Where possible, propellants would be recovered and reused. Aging motors that contain flaws would likely be decommissioned using open detonation.... Solid rocket propellant would be removed for reclamation or burning in a controlled environment, such as an incinerator. Where practicable, incineration or closed burning of rocket propellant would be performed. Most of the acid and particulates ejected during the burn would be collected in plume scrubber water. This water would be treated for acceptance by a publicly owned (or federally owned) water treatment works in accordance with a National Pollutant Discharge Elimination System (NPDES) permit. (p. 4-16)	Section 4.0 of the BMDS PEIS describes how various activities including "maintenance and sustainment" were considered and analyzed in the PEIS. As described in Section 4.1.1.9, Exhibit 4-2 on Page 4-5, MDA did not consider missile maintenance further in this PEIS because it has been analyzed in previous NEPA documents. Decommissioning of missiles was discussed in Section 4 of the PEIS as identified in the comment. Beyond these activities, site and system specific decommissioning activities will be assessed in appropriate NEPA documentation tiered from the PEIS when decommissiong becomes the next step in the lifecycle of the component or system. Demilitarization and disposal of missile components will be performed in accordance with DoD Directives, Joint Service Regulations, and will comply with all applicable Federal and state regulations.
Propellant	E0429-20, PHW0004-20	Once again, the PEIS authors don't seem to be reading the newspapers. The disposal of solid rocket propellant	Section 2.1.3.2 of the BMDS PEIS describes the spiral development process which will be used to determine

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		through "hog-out" (washing out the propellant) or open burning/open detonation are some of the major sources of perchlorate contamination across the country. The PEIS should note how much propellant will be used, how often it will be necessary to dispose, and what the environmental impacts of each disposal or treatment method are likely to be. Such information is necessary, not just to estimate the life-cycle costs of the program, but also to figure out in advance how to reduce financial costs and environmental impacts through system redesign or ongoing mitigation activities. That's the purpose of the NEPA process.	which components will be transitioned to the military service responsible for deployment, operation and maintenance. The PEIS does not attempt to detail the architecture of the deployed BMDS. The PEIS states "Thus the MDA can consider deployment of a missile defense system that has no specified final architecture and no set operational requirements but which will be improved incrementally over time." Therefore, it cannot be said with certainty how much propellant will be used or how often it will be necessary to dispose of propellant. The DoD is exploring new technologies for disposal of ammonium perchlorate contaminated wastewater including using a biodegradation system and will use this and other new technologies as appropriate to dispose of wastewater. (U.S. Department of Defense, 2003. Joint Demilitarization Technology Program: A Report to Congress, http://www.dtic.mil/biosys/org/demil_rept2003_final.pdf accessed December 20, 2004)
Propellant	PHO0025-3	The disposal of solid rocket propellant through washing out, propelling or open burning, open detonation are some of the major sources of perchlorate contamination across the country.	Historically, the manufacturing and disposal of solid rocket propellant that contains ammonium perchlorate as an oxidizer has led to perchlorate contamination. There is no evidence to suggest that burning solid propellant in a SRM leads to emissions of perchlorate to the atmosphere. Perchlorate could be released into the environment in the form of uncombusted solid rocket propellant from a non-nominal launch or other accident causing release of solid propellant to land or water. These have been considered in the PEIS. Additional information on perchlorate has been added to the PEIS text as well as a technical appendix (Appendix M) on

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
			perchlorate. This appendix considers the uses, sources, and disposal of perchlorate as well as the human health and ecological risk of exposure to perchlorate.
Propellant	PHO0037-2	Number one, exposure to increased levels of toxic pollutants from a dramatic increase in missile launches. Liquid propellants containing hydrozene, nitrogen tetroxides and other compounds that are highly toxic. In addition, ammonium perchlorate, which is used in solid propellants, it blocks the formation of key thyroid elements that are critical for growth and development, especially in fetuses and children, and this was not considered.	The impacts of accidental exposure to various propellants are discussed in Section 4.1.1.2 of the PEIS. This section of the Final PEIS has been modified to include additional information regarding the potential impacts of perchlorate. The DoD and the MDA are aware of the potential health concerns associated with perchlorate contaminated water and of the various Federal and state initiatives to address this issue. A technical appendix (see Appendix M) addressing issues specifically related to perchlorate has been added to the Final PEIS. The appendix considers the uses, sources, and disposal of perchlorate as well as the effects on human health and the environment. The DoD and the MDA are aware of the NRC study that considered thyroid function in infants including possible impacts from perchlorate exposure on birth defects and skeletal growth. Regarding birth defects resulting from non-normal thyroid function the NRC study states: *"The consequences of severe combined maternal and fetal hypothyroidism during fetal life and in newborn infants include microcephaly (small brain), mental retardation, deaf-mutism, paraplegia or quadriplegia, and movement disorders. Those abnormalities are not reversible by treatment with T4 (Foley 2000). However, the abnormalities can be largely prevented by administration of iodide to the mothers before or*

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
			during the first trimester and early part of the second trimester of pregnancy (Pharoah 1993; Cao et al. 1994).” Regarding impacts to skeletal growth from non-normal thyroid function, the NRC study states: *“T4 and T3 also are required for normal skeletal development and growth. Bone cells have T3 receptors, and T3 stimulates bone formation and the appearance of the epiphyseal centers that are needed for normal growth of long bones. T3 also stimulates the production of pituitary growth hormone and insulin-like growth factor. Treatment with T4 leads to resumption of bone growth and skeletal maturation, but severely affected infants are unlikely to have normal stature.”*
Propellant	PHO0038-5	The hydrozenes that Jean mentioned were the same things that I believe came from when the space shuttle crashed and landed in Texas and there was a very large mobilization to get people not to touch those things. And if that's the same chemical that's going up with each of these launches and potentially coming back down, then those will be grave consequences indeed.	Hydrazine is one of the propellants used as part of the NASA's Space Shuttle program. Following the loss of Space Shuttle Columbia the public was requested to notify NASA as to the location of debris. Some reports stated that there was a potential for debris to be contaminated with hydrazine. However, most experts agree that there would be little to no possibility of finding hydrazine contaminated debris after an accident of this type. Hydrazine is a highly volatile substance and would not be expected to persist in an open environment for extended periods of time. The impacts to the environment from the use of hydrazine for BMDS launches are discussed in Section 4.1.1.2.

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
Noise	E0431-1	An increase of 1 dB is not a doubling of sound energy. Decibel are on a quasi-logrithmic scale and it does not function like the Richter scale. An increase of 3 dB is a doubling of sound and pressure.	The commenter is correct, an increase of 3 decibels (dB) would occur as a result of doubling sound pressure. The text of the document has been modified to further clarify this and other information on noise.
Noise	E0431-2	dBA is not used to assess human reaction to a single noise event averaged over a 24-hour period. dBA is measure of sound pressure using the A-weighted scale. Many other acoustical metric are used to assess human reaction, including Leq - equivalent noise level, sound exposure level, Ldn, etc.	A-weighting is used to sum noise levels as a function of frequency to a single number, expressed in dB as A-weighted decibels (dBA). A-weighting roughly corresponds to the frequency response of the human ear. Noise metrics such as equivalent noise level (L_{eq}), Sound Exposure Level (SEL) and Day Night Average Noise Level (DNL - a 24 hour average noise level with a 10 dB nighttime noise penalty) are used to reduce noise time-history data to a single number. However, dBA can be used in conjunction with temporal noise metrics such as L_{eq}. For example, highway noise studies typically express noise levels in terms of 1 hour L_{eq}, dBA. Instantaneous sound pressure level, expressed as dBA, is typically not used to assess human annoyance. L_{eq} and DNL are typically used to assess human annoyance because these metrics have been found to correlate well with human annoyance. Many Federal agencies use DNL to assess human annoyance, yet the application of DNL to a noise environment consisting of infrequent and loud single events can be problematic. Nevertheless, extensive research has been conducted to ascertain the suitability of DNL in such noise environments. The FAA uses DNL where the noise environment of a typical airport is comprised of discrete and loud noise events. A more

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
			dramatic example is the U.S. Army's use of DNL to characterize the noise environment in the vicinity of weapon firing ranges. The U.S. Army has identified various means of correcting for impulsive weapon noise by using the C-weighting scale (which does not roll off low-frequency signal content).
Generic	E0162-1	The PEIS could make a useful contribution by analyzing how to judge the effectiveness of a system with no operational requirements.	The goal of the NEPA process as established by the CEQ guidelines implementing NEPA is to help public officials make decisions that are based on understanding of environmental consequences, and take actions that protect, restore, and enhance the environment. The CEQ does not indicate that the NEPA process itself should consider the effectiveness of the action being proposed. The MDA decision makers will base their decision about whether and how to implement the BMDS after careful consideration of the environmental analysis presented in the PEIS as well as other operational and policy considerations. It is not the role of the PEIS to determine the operational effectiveness of the proposed system only to evaluate the environmental impacts of the proposed alternatives to provide the decision makers with the information necessary to inform and support their determination.
Generic	PHO0044-7	Finally, the spiral development approach seems to preclude any meaningful assessment. The PEIS could make an useful contribution by analyzing how to judge the effectiveness of the missile defense with no specified architecture and no operational requirements.	See previous response.
Generic	E0319-22	The 1990 Clean Air Act Amendments identified 188 chemical pollutants which cause or contribute to cancer, birth defects, genetic damage, and other adverse health	The PEIS addresses the potential impacts on air quality and on health and safety resulting from the activities associated with the proposed BMDS. After reviewing

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		effects. "The PEIS has not identified any environmental health and safety risks that may disproportionately affect children, in compliance with Executive Order (EO) 13045 as amended by EO 13229" (PEIS page 4-134, Section 4.7). Executive Order 13045 of April 1997, states that each Federal agency, including the Department of Defense (as defined in 5 U.S.C.102) a. shall make it a high priority to identify and assess environmental health risks and safety risks that may disproportionately affect children, and b. shall ensure that its policies, programs, activities, and standards address disproportionate risks to children that result from environmental health risks or safety risks.	the environmental analysis of these potential impacts and the potential impacts to all resource areas defined in the PEIS the MDA did not identify any environmental health and safety risks that may disproportionately affect children. The analysis of these impacts is presented in Section 4 of the PEIS.
Generic	E0347-4	There is no adequate official scientific study of the biological effects on plant, animal and the human body resulting from Fylingdales' radar emissions. Professor Dave Webb, Chair of Yorkshire Campaign for Nuclear Disarmament, has published a paper, Is it Safe?' which can be read at http://cndyorks.gn.apc.org/fdales/. Professor Webb maintains that the safety standards are inadequate and presents the evidence to substantiate his arguments. The reassuring conclusions published in the UK Ministry of Defence's 'Upgrade to RAF Fylingdales Early Warning Radar - Environment and Land Use Report are based on the inadequate safety guidelines. We endorse Prof. Webb's position and submit that his paper be considered by the US Missile Defense Agency as a	The comment has been noted and the reference has been added to the Administrative Record. The environmental impacts on biological resources and health and safety from radar activation are addressed in Section 4.1.1.3 of the PEIS and in technical Appendix N, Impacts of Radar on Wildlife. In addition to the reference mentioned by the commenter, i.e., Final Report, Upgraded Early Warning Radar, Fylingdales, UK, 7 April 2003, another official scientific study that considered Fylingdale's radar emissions is the NRC of the National Academies of Science *Assessment of Potential Health Effects from Exposure to PAVE PAWS Low-Level Phased-Array Radiofrequency Energy* published in 2005. The PEIS is a programmatic analysis; site-specific analyses would tier from this PEIS and would focus on unique aspects of these particular sites. MDA in its overseas activities has

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		contribution to public responses to the Programmatic Environmental Impact Statement.	and will comply with applicable EOs and DoD directives (see Section 4.1.3 and Appendix G). MDA has previously reviewed our activities at Fylingdales and made the appropriate determinations in compliance with applicable EOs and DoD Directives.
Generic	E0347-5	Both Fylingdales and Menwith Hill are sites of prehistoric importance known to date from the Neolithic period or earlier. Conservation of the archaeological heritage is a prime consideration in Britain and must be considered in the deliberations for the US Missile Defense Agency's Programmatic Environmental Impact Statement. The damage to these sites so far is incalculable. Herewith two examples: Menwith Hill: The Base is located on Forest Moor, an area of significance to archaeologists for its Neolithic settlement, testified by the wealth of flint microliths. The site is adjacent to an Iron-Age Brigantian Fort. The Roman Road joining the fort at Ilkley (Olicana) to the city of York (Eboracum) borders the southern boundary of the Base. The US occupants in c.1990 removed an ancient megalith known as Tibby Bilton', possibly the last standing remnant of a prehistoric group or circle of standing stones. Fylingdales (or more properly, Snod Hill): The presence of a tumulus, a group of (fallen) megaliths and petroglyphs is evidence that Snod Hill is a prehistoric funerary site.	Section 3.1.4 of the PEIS discusses why cultural resources, which include historical and archaeological concerns, are most appropriately analyzed in site-specific documentation. This section of the PEIS emphasizes that because of the unique qualities and characteristics, cultural resources should be characterized and analyzed for specific activities proposed at particular locations. The MDA has and will comply with EOs and DoD Directives applicable to MDA overseas installations and activities. (See Section 4.1.3 and Appendix G.) MDA has previously reviewed our activities at Fylingdales and made the appropriate determinations in compliance with applicable EOs and DoD Directives. If additional BMDS activities were proposed for sites such as Fylingdales, site-specific analyses including potential impacts on cultural resources would be prepared, as appropriate.

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		Snod Hill is crossed by prehistoric trackways, ancient rights of way dating from the Bronze Age or earlier, for over two thousand years in use as a 'Salt Road' from the coastal settlements. The Salt Road is notorious in later history as a route for smugglers. The Salt Road was closed peremptorily and permanently to permit the construction of the Early Warning Radar facilities.	
Generic	E0429-6, E0429-25	2. Consider in detail the management practices-launch protocols, treatment technologies, etc.-necessary to mitigate the significant environmental impacts, including increased depletion of the stratospheric ozone layer and the likely release of perchlorate into groundwater, surface water, and soil.	Because of the programmatic nature of this document it is not possible to consider specific management practices that would be imposed at specific ranges where proposed BMDS activities would occur. Appropriate guidelines and protocols are developed prior to each test and are designed to address the unique features of the test. In addition, please note that the PEIS did not identify any significant programmatic environmental impacts that require mitigation. If BMDS activities are proposed at specific locations, future analyses may reveal the potential for significant impacts which could require mitigation.
Generic	F0004-7	6 Keep it clean wherever, you go to put this all in. Clean all your toxic wastes + garbages. Kodiak Island is one of the most pristine places left on this planet...Please keep it that way - Please. Our close ocean waters are Our Living they must be kept clean + respected!	The potential environmental impacts associated with the disposal of hazardous materials and hazardous wastes and health and safety are discussed in Section 4 of the PEIS. The environmental impacts associated with specific locations such as the KLC would be discussed in site-specific environmental analyses, as appropriate.

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		Rockets + missile debrie and fish - just don't mix! And Las but NOT least...just be real damn careful out there. I love that island and want to keep it safe.	
Generic	M0267-1	Orbital debris: Testing and deployment of space-based interceptors can significantly increase space debris, endangering other objects in space, in the air and on land. We agree with the commentators from the Center for Defense Information that the PEIS does not answer sufficiently to these problems and dangers. We suspect the detrimental environmental effects are great enough in themselves to warrant cancellation of this portion of the program.	Please refer to responses to comments on orbital debris above. The MDA will announce a decision regarding the proposed activities considered in the PEIS through the issuance of a ROD.
Generic	M0267-2	Laser and kinetic kill weapons: The PEIS does not really deal with the detrimental environmental effects that will result from the process of developing, testing and deploying laser and kinetic kill weapons. Yet, these weapons are integral to the entire program. We understand there are still many problems to be solved if these science fiction fantasies are to be translated into reality. These problems and the dangers posed to the environment should be included in the PEIS. We suspect that they are great enough to warrant cancellation of the space weapons program.	The environmental impacts associated with the use of directed energy or laser weapons is considered in Section 4.1.1.1 (Weapons - Lasers) and the use of kinetic energy weapons or interceptors is considered in Section 4.1.1.2 (Weapons - Interceptors). The MDA will announce a decision regarding the proposed activities considered in the PEIS through the issuance of a ROD.
Generic	M0268-3	Hazards of use: Completely missing in this PEIS is an analysis of the hazards of use if the BMD system is ever employed. This is not a benign system, and possible hazards should be investigated. What would be the effect of a successful intercept over the Pacific Ocean or seconds after firing by another nation? What would be the extent of nuclear fall-out or the expectations of damage from an explosion of the incoming weapon? What would be the	The environmental impacts of intercepts of target missiles have been considered in Sections 4.1.2 and 4.2.2 of the PEIS. The impacts of the intercept of a threat missile launched at the U.S. by another nation would create a national security situation and perhaps lead to a war and as such would be considered outside of the scope of this NEPA analysis.

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		environmental effect of a successful intercept of a nuclear weapon over the United States, resulting in a high altitude nuclear explosion? Could electrical and communications systems across the US be destroyed? Could satellites be destroyed? Is it possible that the use of these interceptors to protect U.S. citizens could actually result in unintended destruction? Might other non-U.S. territories, in the path of the weapons, be harmed by interceptions and nuclear explosions above their areas or by debris falling onto their territory? What will be the possible effects on people and the environment on earth below if MDA war fighters actually use their weapons in space or in the skies?	
Generic	PHO0047-4	You know, I'm not sure what kind of chemical you use or you put in a missile testing or in the warhead when you intercept it in space, but all over the years that you have been doing the testing between Kwajalein and Vandenberg, has there been any environmental study of all the debris that has fallen down into the ocean to find out how contaminated the area is and how far spread the contamination is? Has there been anything done like that? And have the people been aware of what has been done or has not been done?	The PEIS considers the potential impact of debris created as a result of BMDS activities including the launch and intercept of target and interceptor missiles. In addition, previous environmental analyses produced for specific tests occurring between Kwajalein and Vandenberg AFB considered these types of site-specific issues as appropriate. Many of the references that contain these environmental analyses are available for download from the MDA PEIS web site.
Generic	PHW0002-5	The draft PEIS fails to fully address the effects of other types of debris - rocket fragments, fuel, and so forth. Again, it barely scratches the surface of potential harmful consequences that could plausibly result from the alternatives listed, and again, it immediately dismisses the few consequences that are divulged. Debris that could fall into the ocean "would become diluted and would cease to be of concern." (p. 4-51) Debris that survived reentry is not to be worried about, as it would fall into a pre-	The impacts of debris from launches of interceptors are considered for each resource area in Section 4.1.1.2. It should also be noted that, where appropriate, separate analyses are recorded for launch debris impacting on land and in water. These discussions include the potential impacts from interceptor or target hardware as well as propellants.

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
		established footprint, and even if it didn't, "Debris is more likely to terminate in water than on land because water covers 75 percent of the Earth's surface." (p. 4-119) Debris from spills or intercepts in the air is assumed to dissipate before it hit the ground. (p. 4-24)	
Generic	PHW0002-6	Yet this is making a real leap of faith in how these actions would affect the environment, and doing so in a manner that precludes any real assessment of what sort of consequences could occur. The treatment of the Airborne Laser (ABL) is indicative of this attitude. The draft PEIS says that should the ABL not able to land at "an appropriate location," its fuel and laser chemicals may have to be jettisoned, but this would be at a minimum altitude of 15,000 feet and thus "would be diluted in the atmosphere." (p. 4-24) And if there was an accidental fire on the ABL, "the liquid and solid laser chemicals would be consumed or contained." (p. 4-34) These laser chemicals include hydrogen peroxide, ammonia, chlorine, helium, and iodine, according to the document, (p. 4-24) No explanation is given as to what would happen should the ABL jettison its chemicals at a lower altitude than 15,000 feet, nor how exactly the fire would contain all chemicals. The draft PEIS makes these reassuring statements with no solid evidence to back them up.	The PEIS states that the minimum altitude that laser chemicals would be jettisoned is 15,000 feet; therefore, no discussion of the potential impact of their jettison below 15,000 feet was necessary. As stated in the PEIS, in the event of an accidental fire on the ABL the laser chemicals would either be consumed in the fire or would be contained. The containment would be within the body of the aircraft and therefore the chemicals would not impact the external environment.
Generic	PHW0004-6	2. Consider in detail the management practices-launch protocols, treatment technologies, etc.-necessary to mitigate the significant environmental impacts, including increased depletion of the stratospheric ozone layer and the likely release of perchlorate into groundwater, surface water, and soil.	Because of the programmatic nature of this document it is not possible to consider specific management practices that would be imposed at specific ranges where proposed BMDS activities would occur. Appropriate guidelines and protocols are developed prior to each test and are designed to address the unique features of the test. In addition, please note that the PEIS did not identify any

Exhibit K-3. Responses to Comments – Environmental Impacts

Issue Topic	Comment Number	Excerpt Text	Response
			significant programmatic environmental impacts that require mitigation. If BMDS activities are proposed at specific locations, future analyses may reveal the potential for significant impacts which could require mitigation.
Generic	PHW0004-25	2. Consider in detail the management practices-launch protocols, treatment technologies, etc.-necessary to mitigate the significant environmental impacts, including increased depletion of the stratospheric ozone layer and the likely release of perchlorate into groundwater, surface water, and soil.	See previous response.

Exhibit K-4. Responses to Comments – Miscellaneous

Issue Topic	Comment Number	Excerpt Text	Response
Accidents	F0004-4	3 When you have another accident like the one on Nov. 09, 2001 where the rocket Blew-up, Tell us the truth right away. Don't lie then tell the truth (forced as it was) 6 mos. later. Maybe if you don't try launching in 40 mph winds with snow + rain you might have a better launch window + help the process a lot...	There are inherent risks with any missile testing activity; however, protection of life and property, on and off range, is the prime concern of Range/Mission Safety personnel. The RCC Common Risk Criteria for National Test Ranges (RCC 321-02) sets the requirements for minimally acceptable risk criteria to occupational and non-occupational personnel, test facilities and non-military assets during range testing operations. Under RCC 321-02, individuals of the general public shall not be exposed to a probability of fatality greater than 1 in 10 million for any single mission and 1 in 1 million on an annual basis. Range Safety personnel also apply launch window criteria that consider various weather and climatic conditions, as appropriate.
Accidents	PHO0047-3	Or at least reassure the people that there's not going to be any accident happening. But we cannot say that there's not going to be any accident. There's no guaranty. No matter what, there's no guaranty. And if something happens, what are the people going to do?	As noted in Sections 4.1.1.1 and 4.1.1.2, Health and Safety, restricted areas are established to protect the public from launch and laser activities. These areas are established so that debris from non-nominal launches or the use of a flight termination/thrust system would not impact populated areas.
Nuclear	E0162-9	7) In addition to "hit-to-kill" interceptors and directed-energy weapons, there have been reports that interceptors armed with nuclear weapons are also being considered for missile defenses. The PEIS should indicate what research and development work is being planned for such weapons as part of the Advanced Systems in Appendix F. How would such systems be tested without violating the Limited Test Ban Treaty and the Comprehensive Test Ban Treaty?	As noted in Section 2.2.1.1, BMDS interceptors would use non-nuclear hit-to-kill or directed blast fragmentation technology to destroy a threat missile. No nuclear material will be used in any BMDS test systems. Any space-based interceptors that would be launched from a space-based platform would use propellants as indicated in the PEIS. No nuclear materials would be used to fuel the interceptors. Further, the interceptors would use non-nuclear hit-to-kill or directed blast

Exhibit K-4. Responses to Comments – Miscellaneous

			fragmentation technology to intercept and destroy a threat missile.
Nuclear	E0363-3	Finally, it would be environmentally catastrophic if these weapons were ever actually used in war. The hazards of use, including high altitude nuclear explosions, are not discussed in the PEIS but should be addressed.	See previous response.
Nuclear	E0380-2	2) The PEIS completely ignores the well known environmental impacts of radiation. It does so by maintaining the transparent fiction that an effective BMDS can be implemented without resorting to the use of nuclear war heads. Current research with BMDS prototypes provides scant basis for the belief that lasar or kinetic weapons will serve to eliminate target warheads. A realistic PEIS for BMDS must include a full and detailed consideration of the environmental impacts of nuclear weaponry. Such an assessment must address the entire nuclear cycle - production and manufacture as well as decommissioning and waste storage.	See previous response.
Nuclear	E0395-1	With respect to what the overall BMDS actually could entail, the PEIS is so broad and generalized that it is not possible to know what is covered by the overall BMDS PEIS and what isn't. For example, nuclear-tipped interceptors have been discussed by MDA officials but are not addressed in this PEIS. The extent and limitations of this PEIS should be clearly stated.	See previous response.
Nuclear	E0402-5	2) Radioactive fallout from intercepted missiles has not been considered in this PEIS. The accepted concept that a missile blown up in the outer reaches of the atmosphere is the logical conclusion of the BMDS alone should keep us	There would be no radioactive or biological material from missile intercepts during system integration testing of the proposed BMDS. Such material would not be used in any targets used for intercept and would only be

Exhibit K-4. Responses to Comments – Miscellaneous

		from deploying such a system and rather focus on truly preventative strategies that do not accept any nuclear weapon use by any country.	expected in enemy missiles which would be launched to attack the U.S. Any intercepts resulting from such an act of war upon the U.S. would not need to be considered in this PEIS, because as the commenter correctly points out the effects of war are normally excluded from analysis under NEPA.
Nuclear	E0424-2	e) The potential radioactive fallout from intercepted missiles.	See previous response.
Nuclear	E0427-17, E0439-17	16) Will any interceptors use nuclear warheads? The PEIS does not address the inability of mid- course or terminal kinetic interceptors to stop a "threat cloud" once a attack missile has MIRVed, or released many decoys or countermeasures (Richard L. Garwin. Holes in the Missile Shield. Scientific American, November 2004, page 70-79). The MDA may be temped to intercept such a threat by using large nuclear tipped interceptors. The potential use of nuclear tipped interceptors was discussed by high ranking US DOD officials in 2002. http://www.washingtonpost.com/ac2/wp-dyn/A28866-2002Apr10?language=printer. If such nuclear tipped interceptors were deployed, the environmental risks would be much greater. If so, the environmental consequences of the nuclear fallout and electromagnetic pulses from such high altitude nuclear detonations must be considered in detail. This would include analysis of risks to health and safety, contamination of water, land, soils, EMP effects on civilian and medical electrical and computer systems and infrastructure. The MDA should also consider the effects of radioactive fallout on health and safety, biological resources, and contamination of land and water resources.	See previous response.

Exhibit K-4. Responses to Comments – Miscellaneous

Issue Topic	Comment Number	Excerpt Text	Response
		Furthermore, given the historic 15% missile launch failure rate, the radioactive fallout from accidents with nuclear tipped interceptors must be considered in detail. The public should have full opportunity to consider and comment on the use of such nuclear tipped interceptors in this PEIS. The point is that the blast fragmentation devices need to be described in detail to enable adequate evaluation of its environmental effects.	
Nuclear	F0005-20	(6) If interceptors armed with nuclear weapons are being considered or missile defenses, as some reports indicate, the PEIS should indicate what research and development work is being planned for such weapons as part of the Advanced Systems in Appendix F.	See previous response.
Nuclear	E0319-2	1. Whether or not any low-yield nuclear material will be used in the BMDS test systems (boosters, payloads, dummy warheads, satellites, interceptors, targets, radar systems) 2. Whether or not any low-yield nuclear material will be stored at Research Development Test Sites 3. If depleted uranium will be used in/on target missiles, interceptors, satellites, boosters, etc. 4. If depleted or spent uranium will be stored at Research, Development Test Sites	The PEIS states that interceptors may use non-nuclear lethality enhancers to increase the probability of a successful intercept. None of the components or the integrated system described in the BMDS PEIS would use nuclear material. Neither low yield nuclear material nor depleted uranium would be used in any BMDS test systems nor stored at any research and development test site.
Nuclear	E0319-19	Include in the PEIS the projected cumulative impacts from 'radiation fallout' for all space-based weapon systems (lasers, interceptors, warheads, e.g.).	There would be no radioactive or biological material from missile intercepts during system integration testing of the proposed BMDS. Such material would not be used in any targets used for intercept and would only be expected in enemy missiles which would be launched to attack the U.S. Any intercepts resulting from such an act of war upon the U.S. would not need to be considered in

		Entire journal dedicated to the effects of nuclear war, including effects on heath and safety. Air, water resources, agriculture, biological resources, and nuclear winter.) This request in my scoping comments was ignored, e.g. Scoping comment "#18) The MDA needs to consider whether the BMDS in conjunction with offensive first strike weapon systems and first strike policy increase the probably of a major nuclear war or other disturbance that could result in nuclear Winter, with the associated loss of species"	
Nuclear	PHO0011-5	Also, will the space-based satellites use nuclear power sources? Will any BMDS interceptors use nuclear warheads? This was not clearly defined. This is unsatisfactory.	See previous response.
Nuclear	PHO0050-1	For example, I read all of the material out there. I don't even see the word "depleted uranium."	None of the components or the integrated system described in the BMDS PEIS would use nuclear material. Neither low yield nuclear material nor depleted uranium would be used in any BMDS test systems nor stored at any research and development test site.
Nuclear	E0319-8	The MDA has never referenced or included discussion on the INF Treaty MOU in any previous EA or EIS in regard to missile defense testing, nor is it discussed in the BMDS Draft PEIS. Why not? Why is the MDA avoiding this issue? Nor has the MDA referred to or listed the Research and Development test site locations in Alaska on the INF Treaty MOU list (e.g. Kodiak Launch Complex, Alaska and Poker Flats Rocket Range, Alaska). The MDA's avoidance of discussion on these test launch sites, leaves open the question as to whether or not nuclear material can and will be launched from these test-site locations on future targets, interceptors, boosters, dummy warheads or	Once plans for launching targets are sufficiently detailed, the plans are reviewed for compliance with all applicable arms control treaties, including the Intermediate-Range Nuclear Forces (INF) and Reduction and limitation of Strategic Offensive Arms Treaty (START) Treaties, if appropriate. Because it is the policy of the DoD to ensure that all DoD activities comply fully with U.S. arms control agreements, no activities will be conducted that would violate any such agreement. The PEIS considers international treaties and law in conjunction with EO 12114, Environmental Effects Abroad of Major Federal Actions.

Exhibit K-4. Responses to Comments – Miscellaneous

Issue Topic	Comment Number	Excerpt Text	Response
		used in laser systems. The PEIS should include information on the INF Treaty, the INF Treaty MOU test locations, plus any proposed future plans to use nuclear material as part of ground-based or space-based BMDS testing. The MDA is projecting test plans up to the year 2014, so it already knows if nuclear material is part of the BMDS test system (power for space-based platforms, lasers, etc).	As noted in Section 2.2.1.1, BMDS interceptors would use non-nuclear hit-to-kill or directed blast fragmentation technology to destroy a threat missile. Neither low yield nuclear material nor depleted uranium would be used in any BMDS test systems nor stored at any research and development test site.
Nuclear	E0387-5	Further to this, plans for weapons such as the space-based laser may eventually incorporate the use of nuclear power. The deployment of nuclear powered satellites could be environmentally disastrous with considerable risk of high-level pollution at the point of initial launch, when in orbit (from attack or accident) and (if and when the orbit decays) during re-entry into the Earth's atmosphere	The space-based weapons platform described in Alternative 2 of the BMDS PEIS does not include the use of lasers or the use of nuclear power sources for the weapons platform. If the proposed design of the space-based weapons platform changed, the MDA would prepare additional environmental analyses, as appropriate.
Nuclear	E0395-10	The use of radioactive sources on missile defense satellites, either for surveillance, target tracking and target discrimination, or on space-based missile defense interceptors is not discussed.	As noted in Section 2.2.1.1, BMDS interceptors would use non-nuclear hit-to-kill or directed blast fragmentation technology to destroy a threat missile. No nuclear material will be used in any BMDS test systems. The space-based platforms for weapons and sensors described in the BMDS PEIS do not include the use of radioactive materials. If the proposed design of these space-based platforms changed, the MDA would prepare additional environmental analyses, as appropriate.
Nuclear	PHO0011-7	Also, the PEIS, has not considered any -- has not considered any radioactive follow-up from interceptive missiles.	There would be no radioactive or biological material from missile intercepts during system integration testing of the proposed BMDS. Such material would not be used in any targets used for intercept and would only be expected in enemy missiles which would be launched to attack the U.S. Any intercepts resulting from such an act

Exhibit K-4. Responses to Comments – Miscellaneous

Issue Topic	Comment Number	Excerpt Text	Response
			of war upon the U.S. would not need to be considered in this PEIS, because the effects of war are normally excluded from analysis under NEPA.
Nuclear	PHO0037-5	Six, radioactive fallout from intercepted missiles has not been considered. The effects of war are normally excluded from analysis by NEPA; however, this proposed BMDS action is very likely to provoke a worldwide WMD arms race and force other nations to prepare to launch a massive retaliation against the U.S. should war ensue. And I believe that radioactive fallout needs to be looked at and not written off as a no significant impact.	See previous response.
Treaties	E0162-4	2) The PEIS should examine in detail treaty compliance of various BMDS tests. The draft PEIS has no discussion of INF Treaty restrictions on long-range air-launched and sea-launched targets or START Treaty restrictions on sea-launched targets even though I raised this issue in my scoping comments. (See fourth comment on page B-15.) The GMD ETR EIS did not consider treaty compliance despite the fact that previous analyses (1994 TMD ETR EIS and 1998 TMD ETR Draft Supplemental EIS) did consider this issue. The 1994 TMD ETR EIS refers to the INF treaty prohibition of air-launched and sea-launched missiles with ranges between 500 and 5,500 kilometers. The 1998 TMD ETR DSEIS notes that the START treaty prohibits launches from sea-based platforms and that launches from ships are restricted to ranges less than 600 kilometers. If subsequent compliance reviews of air-launched and sea-launched targets have been done, they should be discussed in the PEIS and references to them should be cited. I was assured at the 26 Oct. meeting in Honolulu that this would be considered.	Once plans for launching targets are sufficiently detailed, the plans are reviewed for compliance with all applicable arms control treaties, including the INF and START Treaties if appropriate. Because it is the policy of the DoD to ensure that all DoD activities comply fully with U.S. arms control agreements, no activities will be conducted that would violate any such agreement. The PEIS considers international treaties and law in conjunction with EO 12114, Environmental Effects Abroad of Major Federal Actions.

Exhibit K-4. Responses to Comments – Miscellaneous

Issue Topic	Comment Number	Excerpt Text	Response
Treaties	F0005-16	(2) The draft PEIS contains no discussion of INF Treaty restrictions on long-range air-launched and sea-launched targets, or START Treaty restrictions on sea-launched targets. Accordingly, the PEIS should examine in detail treaty compliance of various BMDS tests.	Launches of air-launched and sea-launched targets would be reviewed for compliance with all applicable arms control treaties, including the INF and START Treaties as appropriate. Because it is the policy of the DoD to ensure that all DoD activities comply fully with U.S. arms control agreements, the MDA would conduct no testing activities that would violate any such agreements.
Treaties	E0319-8	The MDA has never referenced or included discussion on the INF Treaty MOU in any previous EA or EIS in regard to missile defense testing, nor is it discussed in the BMDS Draft PEIS. Why not? Why is the MDA avoiding this issue? Nor has the MDA referred to or listed the Research and Development test site locations in Alaska on the INF Treaty MOU list (e.g. Kodiak Launch Complex, Alaska and Poker Flats Rocket Range, Alaska). The MDA's avoidance of discussion on these test launch sites, leaves open the question as to whether or not nuclear material can and will be launched from these test-site locations on future targets, interceptors, boosters, dummy warheads or used in laser systems. The PEIS should include information on the INF Treaty, the INF Treaty MOU test locations, plus any proposed future plans to use nuclear material as part of ground-based or space-based BMDS testing. The MDA is projecting test plans up to the year 2014, so it already knows if nuclear material is part of the BMDS test system (power for space-based platforms, lasers, etc).	The proposed BMDS would use hit-to-kill or directed fragmentation intercept technologies or directed energy weapons to destroy threat missiles. No nuclear materials are proposed for use with the system. Testing of BMDS components would be reviewed for compliance with all applicable arms control treaties, including the INF and START Treaties as appropriate. Because it is the policy of the DoD to ensure that all DoD activities comply fully with U.S. arms control agreements, the MDA would conduct no testing activities that would violate any such agreement.
Treaties	PHO0044-1	There's no examination of treaty restriction on target launches in this EIS, no quantitative information on the liabilities of rocket boosters.	BMDS flight testing is carried out in conformance with all applicable treaties and international agreements. It is not clear what liabilities of rocket boosters the commenter is referring to. All tests receive thorough

Exhibit K-4. Responses to Comments – Miscellaneous

Issue Topic	Comment Number	Excerpt Text	Response
			safety and risk evaluations at the relevant range/test facility from which any test launches are scheduled to occur. This includes flight trajectory and debris impact hazard zone in the event of a non-nominal launch.
Treaties	PHO0046-5	So the Programmatic EIS fails to analyze how the proposed BMDS system will affect the international security environment, how will it impact international laws and treaties such as prohibitions on the weaponization of space. And that's one of the explicit options for the Ballistic Missile Defense System. So that goes against established agreements to keep space for peace.	The PEIS considers the potential environmental impacts of feasible options for proposed BMDS systems implementation including the placement of interceptors in space. The MDA conducts all testing in accordance with all applicable treaties and international agreements.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
Alternatives	E0395-7	Historically, missile defenses have been divided between battlefield-theater defense and strategic defense. All previous administrations kept these two aspects of missile defenses segregated. A fourth alternative could be to develop and integrate theater defenses while postponing defenses to strategic attack.	As noted in Sections 1.4 and 2.6, MDA has evaluated the threat environment and concluded that an effective missile defense should include defense against ballistic missiles in all phases of flight and components based at least on air, sea, and land to meet the threat. Alternatives that provide only one platform or do not address all phases of flight under the current threat would reduce the capability of BMDS to defend the U.S., its deployed forces, allies, or assets from a ballistic missile attack. The proposed alternatives necessarily include a theater or regional defense as the BMDS would better defend against an attack in all phases of flight, not just the terminal phase of the attack. In addition, the U.S. cannot discontinue activities being considered for integration into the BMDS. This would decimate some of the basic defense systems of the U.S. In situations where the proposed action is to integrate existing programs, the no action alternative would be to not integrate the existing programs.
Alternatives	E0427-22, E0439-22	21) Alternative 3: Not developing, or building the BMDS or any of its components and instead renegotating an expanded and verifiable ABM / BMDS treaty: The ABM treaty helped to stabilize and de-escalate the nuclear arms race for all of its 29 years of existence. No country dared attack the US with nuclear missiles, in part because the U.S. would know exactly where the missile came from and have the clear ability to retaliate and bomb them into obivilion. That is certainly still the case. This option would preserve deterrence and peace. Yet it would enable	See previous response.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		the nuclear nations to abide by the NPT and reduce the overall level of nuclear weapons, in exchange for non-nuclear nations not developing nuclear weapons.	
Alternatives	PHO0023-2	And in addition, theater defenses have a realistic success because the boost phase of a missile is relatively slow and even the descent of a short-range, medium-range missile is much slower than that of the strategic missile, which could be traveling at 10 kilometers per second, which makes it very unlikely to hit. The alternative, it may be politically impossible for you to do this, but I think you should try to have another alternative which would simply be to keep the -- this is probably the presidential candidate John Kerry's position on these matters -- would be to move ahead on theater defenses but to maintain the strategic weapons that the missile defense is -- against long-range missiles to be held in research and development stage. And -- and that would be my suggestion for a true alternative.	See previous response.
Alternatives	E0427-23, E0439-23	22) Alternative 4: Preserving Space for non-military purposes. The MDA should consider the alternative of not militarizing space. The planned US militarization and domination of space as described in the US Space Command Vision for 2020 (http://www.fas.org/spp/military/docops/usspac/lrp/ch02.htm) and as described in the 2002 US defense guidance policy and elsewhere, will certainly create and intensify conflicts over the control of space for years to come. These US policy documents talk about "Full Spectrum Domination", "negating" or "destroying" the enemy's satellites and use of space. As US citizens we would like for the US to protect space from militarization, but do we	The MDA has carefully reviewed and considered all alternatives provided as part of the scoping and public review process for the BMDS PEIS. Please note that Alternative 1 considers the implementation of the BMDS without the use of space-based weapons. Thus, an alternative that does not include the use of weapons in space has been considered in the PEIS. The DoD relies on the use of space-based assets for communication and data collection for a variety of programs include missile defense activities. The DoD has many assets such as satellites already deployed in space. It would not be a reasonable alternative for the DoD to stop using these

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		want the US to dominate space, and to start a series of space wars? Think about how you would feel if you lived in another nation and some one destroyed your satellites. Would such actions be considered an act of war? Additionally how does the BMDS PEIS affect US compliance with the Outer Space Treaty?	military assets. Therefore, the recommended alternative will not be considered as suggested.
Alternatives	E0427-24, E0439-24	23) Alternative 5: Deployment of a much more limited land and or Sea based theatre BMD that would offer protection from attack by short or intermediate range missiles. For example, rather than develop the extensive land, Sea, air and space based system, the US and its allies could instead deploy a currently available Aegis missile cruiser(s) off of North Korea. Such a small, affordable, alternative system would immediately meet the needs of defending Japan against missiles that might be launched by North Korea without invoking fears that it would be used to enable invasions and/or domination of the world and thereby starting a massive global arms race.	An alternative similar to that suggested by the commenter was considered in Section 2.6.2 of the BMDS PEIS. The MDA determined that alternatives that provide only one or two platforms would reduce the capability of the BMDS to defend against an attack and would not provide an integrated layered defense that could have multiple opportunities to destroy a threat missile. Therefore, alternatives that provide for a BMDS using only one or two platforms were not considered further in the PEIS.
Alternatives	F0005-6	In addition, the purpose of the proposed action also influences how the "no action" alternative should be presented. When the purpose is narrow, encompassing distinct federal action on a new project, the "no action" alternative must address the environmental effects of the action not going forward, including the effects of any probable outcomes that will occur without the project. (Forty Most Asked Questions, 46 F.R. 18026, at Answer 3.) Alternatively, when the project is broad, encompassing the next phase of federal action in a continuing project, as here, the "No action" alternative must consider the effects of "no change" from the present course of action. (See also	The PEIS considered the effects of no action as no change from the status quo of developing and testing individual systems versus the integration and integrated testing of the system.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

		American Rivers v. Federal Energy Regulatory Commission, 201 F. 3d 1186, 1201; 9th Cir. 1999).	
Alternatives	F0005-7	Here, MDA's interpretation of the proposed project purpose and need is internally inconsistent - in one case narrow, in the other broad. The MDA chooses its alternatives based on the narrow purpose of developing an integrated, multi-layered BMDS while its "no action" alternative allowing for continued research and testing of a non-integrated BMDS, implying that the project supports the general purpose of protecting the United States from foreign missile attacks through any means necessary. (PEIS at pp. 1-1 to 1-8, describing the general history of the government's ongoing development of ballistic missile defense programs.) Consequently, in the PEIS, the MDA sets out two internally contradictory positions. On the one hand, the MDA narrows the purpose of the proposed action, and thus the spectrum of alternatives to be considered, to the creation of a singular, integrated; multi-layered BMDS that is not part of a continuing program to protect the U.S. from ballistic missile attacks. On the other hand, the agency relies on the long history of the U.S.'s missile defense actions to frame its "no action" alternative as a "no change" in an ongoing project with the broad purpose of protecting the U.S. from ballistic missile attacks. On either ground, the PEIS fails to meet the NEPA test - that it interprets its purpose too narrowly in order to develop a very narrow spectrum of alternatives, or that it interprets the purpose too broadly in order to assert a "no action" alternative that allows for continuing, non-integrated action - but not both.	See previous response.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
Alternatives	F0005-8	In determining whether the alternatives analyzed within an EIS are adequate, courts have determined that the range of alternatives an agency must consider, although not "self-defining," is "bounded by some notion of feasibility." (Vermont Yankee Nuclear Power Corp. v. NRDC, 435 U.S. 519, 551 (1978). Accordingly, the alternatives examined by an agency must include only those that are reasonable and feasible - i.e., that are "meaningly possible". However, reasonableness is determined through a fact-specific examination of each proposed project because "what constitutes a reasonable range of alternatives depends upon the nature of the proposal and the facts in each case. A flaw in the PEIS is that the range of alternatives considered by the MDA is not adequate, because the agency unreasonably narrowed the range of alternatives to be examined by narrowly interpreting the purpose of the proposed action as the development of a multi-layered ballistic missile defense system. While courts typically afford agencies some discretion in defining the purpose and need of a proposed project, that discretion is limited by the reasonableness of the agency-defined purpose and need. It is also clear that an agency may not characterize its proposed action purpose so narrowly as to avoid its NEPA obligations (See Friends of Southeast's Future v. Morrison, 153 F.3d 059, 1066; 9th Cir. 1998, and Simmons v. U.S. Army Corps of Engineer 120 F 3d 664, 669-670; 7th Cir. 1997). It seems to LAWS that is exactly what the MDA has done here. We doubt that a reviewing court would condone it, or find that when an agency varies	The purpose and need as described in the BMDS PEIS is reasonably drawn to fulfill national security goals and interests as directed by the Congress, the President and the Secretary of Defense. The goal is to successfully defend the U.S., its deployed forces, allies or assets from a ballistic missile attack. MDA has evaluated the threat environment (e.g., potential launch locations, missile flight paths, and target locations) and concluded that an effective missile defense should include components based on at least the land, sea, and air to provide an adequate defense. To meet this goal, the PEIS presents and analyzes reasonable alternatives, which would provide the nation with a BMDS capability to meet any attack in a successful and timely fashion. Alternatives that do not include the means of accomplishing the goals achieved by an effective missile defense would not be reasonable alternatives. The No Action Alternative presented in the BMDS PEIS is appropriate because the proposed action seeks to change the existing missile defense program to meet current threats. In cases where the Federal agency seeks to change existing programs, the appropriate No Action Alternative is to continue the agency's present course of action. Proposals for a No Action Alternatives, which would involve canceling the development of all ballistic missile defense capability development and testing, would eliminate the capability to defend the U.S., its deployed forces, allies, or assets from a ballistic missile attack (should other deterrents fail), and would not provide the means of meeting the purpose of or need for

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		its interpretation in order to avoid its NEPA responsibilities, the PEIS can be found to meet the NEPA standard.	the proposed action as described in Section 1 of the PEIS.
Alternatives	F0005-9	In this connection, the spectrum of alternatives to be considered must be broader than those considered by the MDA. (See Morton, 458 F.2d at 837) Accordingly, a court could find that consistent with its obligations under NEPA that the MDA should have considered as an alternative the Theater Missile Defense System which has already been developed and, therefore, would not require excessive resources to implement. The MDA should also have considered, and included in the PEIS, alternatives that offer a less than complete solution to the problem. To the extent that it hasn't, the MDA should also have analyzed the BMDS platforms for each component and/or defense environment separately. Other options include an analysis of alternatives that include both weapon and non-weapon components, such as integration of land and sea-based platforms only with increased diplomatic efforts. As the Court said in Morton, an agency cannot restrict its alternatives because it is not part of its jurisdiction. Since the BMDS is part of a broader purpose of protecting the U.S., the MDA should have fulfilled its NEPA obligations by analyzing a much broader spectrum of alternatives to achieve this purpose.	As noted in Sections 1.4 and 2.6, MDA has evaluated the threat environment and concluded that an effective missile defense should include defense against ballistic missiles in all phases of flight and that an effective missile defense should include components based at least on air, sea, and land to meet the threat. Alternatives that provide only one platform or do not address all phases of flight under the current threat would reduce the capability of BMDS to defend the U.S., its deployed forces, allies, or assets from a ballistic missile attack. The proposed alternatives necessarily include a theater or regional defense as the BMDS would better defend against an attack in all phases of flight, not just the terminal phase of the attack. In addition, the previous NEPA analyses considering Theater Missile Defense and NMD were incorporated by reference into this PEIS. However, theater and regional defense were not considered sufficient to meet the purposes of an integrated BMDS and were not reconsidered in this PEIS.
Alternatives	M0046-1	This Alternative 4 would include a return to the United Nations disarmament treaty process (which the current Administration is regrettably blocking), and assumption of a lead role in the continual development of enforceable and universally applied international law consistent with	The MDA has carefully reviewed and considered all alternatives provided as part of the scoping and public review process for the BMDS PEIS. In this instance it was determined that the proposed alternative would not meet the purpose and need for the proposed action as

		both the UN Charter and the Universal Declaration of Human Rights. The United States would re-enter that process as the most powerful and most militarized nation in the world and would have no substantial military rivals. This is a rare and critical moment in history and the choice is ours: the United States can lead the way toward a world freed from war with sustainable development and human rights for all - or this nation can drag the human race backward with it into a world ruled by war, military domination and the threat (or use) of weapons more powerful than any known before.	described in Sections 1.3 and 1.4 and does not meet the direction of the President and the U.S. Congress. The BMDS would have the capability of defending the U.S. against an attack for which there was no prior warning, such as advance notification of an armed enemy inter-continental ballistic missile (ICBM) on a launch pad.
Alternatives	PHO0014-1	The alternative of a diplomacy-based defense system is not considered. In fact, diplomacy seems to be a -- a foreign concept to the current Administration.	See previous response.
Alternatives	PHW0008-1	This Alternative 4 would include a return to the United Nations disarmament treaty process (which the current Administration is regrettably blocking), and assumption of a lead role in the continual development of enforceable and universally applied international law consistent with both the UN Charter and the Universal Declaration of Human Rights. The United States would re-enter that process as the most powerful and most militarized nation in the world and would have no substantial military rivals. This is a rare and critical moment in history and the choice is ours: the United States can lead the way toward a world freed from war with sustainable development and human rights for all - or this nation can drag the human race backward with it into a world ruled by war, military domination and the threat (or use) of weapons more powerful than any known before.	See previous response.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
Alternatives	PHO0048-4	But, in addition, you'll notice from reading the two alternatives, they're simply variations on a theme, they're one and the same thing.	The alternatives include very different weapons basing platforms and ultimate capabilities. To provide the requisite multi-layered defensive system, land-, sea-, and air-based platforms were considered with the real alternative of adding space-based weapons platforms. The alternatives are very different and involve different requirements for implementation and testing.
Alternatives	PHW0001-3	One alternative not even mentioned in the PEIS would be to cut the spending in half, to allow the testing of a system to determine if it would eventually work against potential adversaries such as North Korea or Iran.	Budget-based alternatives are not appropriately considered in this PEIS as the Congress deliberates and passes the budgetary specifications for the Department of Defense (DoD), specifically including the MDA.
Alternatives	PHW0001-4	Another would be to look at the realistic likelihood that if the US is ever confronted by a nation such as North Korea or Iran with a tested ICBM with a likely nuclear warhead, the option of military necessity would be to destroy such an enemy ICBM on its launchpad with precision-guided missiles if an attack seemed imminent.	The MDA has carefully reviewed and considered all alternatives provided as part of the scoping and public review process for the BMDS PEIS. In this instance it was determined that the proposed alternative is not "reasonable" as intended in NEPA and therefore, the suggested alternative is not considered in the BMDS PEIS. The BMDS would have the capability of defending the U.S. against an attack for which there was no prior warning, such as advance notification of an armed enemy ICBM on a launch pad.
Alternatives	PHW0002-8	Finally, the alternatives considered but not carried forward are deliberately chosen to showcase the BMDS systems that the Bush administration has been pushing for in the best light possible. The first one is to cancel development of BMD capabilities, which is explained as being an alternative that "would rely upon diplomatic and military measures to deter missile threats against the U.S." (p. 2-68) This is exactly what has kept the United States safe from attack to date, and yet it is summarily dismissed out of hand. The other alternative is to focus on a single- or	Increasingly the reliance upon diplomatic and military measures to deter threats against the U.S. has been seen as ineffective without a working defensive system against threat missile attack. The U.S. can be attacked with loss of life and property given the admission of North Korea that they have nuclear weapons and the effectiveness of a BMDS can only serve to augment the effectiveness of military deterrence against such an attack.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		two-platform BMDS. But, per MDA threat assessments that are not given but merely referred to, it has decided that "an effective missile defense should include components based on at least the land, sea, and air," so a more limited missile defense system simply would not do. (p. 2-68)	
NEPA Process	E0427-25	Thus, a non-proliferation analysis is needed for the BMDS PEIS particularly in regard to a genuine no action alternative.	The DOE review was critical because it involved the use of nuclear power, which is not an issue associated with the proposed BMDS. The proposed BMDS as described in the PEIS does not include the use of nuclear materials; therefore, the environmental impacts of use, storage, or transfer of nuclear material are not discussed in this PEIS. A non-proliferation analysis is not within the scope of the PEIS analysis of the environmental consequences of the BMDS.
NEPA Process	E0427-26	A mainly political justification was also given on BMDS PEIS pages 1-14 for not considering scoping comments showing "concern that the BMDS would create an arms race, especially in space" comments showing "opposition to the development of nuclear weapons and concern that missile defense could be a first strike capability for U.S. worldwide military domination". Specifically, the MDA PEIS stated the rationale for excluding these comments is that "Public comments concerning DoD policy, budget and program issues are outside the scope of the Draft BMDS PEIS". These political justifications used by the MDA are insufficient for excluding these and related issues of non-proliferation from analysis in the BMDS PEIS. A non-proliferation analysis is needed for the BMDS. We all	See previous response.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		want to be safe from missile attack. The non-proliferation analysis is needed to determine if the BMDS is likely to ultimately increase our security, and maintaining environmental quality or result in an out of control arms race that decreases our security and wreaks wide spread environmental destruction. Because of the reasonable foreseeability of increased potential for environmental harm due to proliferation and security risks, I strongly recommend that the MDA prepare a detailed Nonproliferation Impact Review for the BMDS PEIS including a Nonproliferation Impact Review EIS for each BMD component and for each BMD site or location. These reviews will determine the scope and need for a MDA high-level program and the alternative that would cause the least environmental harm. If the BMDS is the best alternative for such a program, these review processes will thoroughly assess the potential proliferation, security and environmental harms and ways to mitigate those potential harms. This will mean that proactive plans to protect the environment, public safety and national security will be developed in advance rather than in response to a problem, accident or crisis.	
NEPA Process	E0427-27	The DOE has set an important precedent by conducting a Programmatic EIS, including a Nonproliferation Impact Review (NIR), for its Civilian Nuclear Energy Research and Development and Isotope Production Missions in the United States, including the Role of the Fast Flux Test Facility in December 2000 and for its Stockpile Stewardship and Management in September 1996. Furthermore, Nonproliferation Analyses were conducted	See previous response.

See previous response.
NEPA Process	F0003-3, M0276-3	c. As suggested by CEQ regulations, MDA has taken advantage of the extensive environmental analyses that already exist for many of the existing components of the proposed BMDS by incorporating these materials into the DPEIS by reference. However, some of these documents are greater than 10 years old. The PEIS should confirm the validity of the information in these documents.	In accordance with 40 CFR § 1502.21, Incorporation by Reference, information that was incorporated by reference in the PEIS has been cited and briefly described in the PEIS and made available during the public review period. The MDA has reviewed the portions of the information from these documents that are incorporated by reference and found them to be valid and relevant to this PEIS.
NEPA Process	F0005-1	For example, Section 1.2 shows that environmental analyses have already been completed for most components, the notable exceptions feeing the Aegis BMD and spacebased weapons. As we understand it,	This PEIS is being prepared to address the potential impacts of alternatives for implementing the proposed BMDS. As described in Section 2.1.3 of the PEIS, the system acquisition process historically has focused on

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		development and testing of most components are well underway and decisions about initial deployment of GBI's and Aegis BMD ships have been made.	the development of independent stand-alone defensive elements. Consistent with this approach, the MDA developed NEPA analyses that appropriately considered the impacts of these stand-alone systems. The MDA is now working to incrementally develop and field a BMDS that layers and integrates defenses to intercept ballistic missiles in all ranges of flight. Therefore, it is now appropriate for the MDA to prepare a PEIS which discusses the environmental impacts of the proposed system as a whole. Future site-specific analyses necessary to support proposes tests or new developments of the BMDS will tier from this PEIS, as appropriate. Therefore, the PEIS is being developed as intended under NEPA as a resource to help MDA decision makers determine the environmental impacts of implementing the BMDS as an integrated system.
NEPA Process	F0005-2	Morever, the spiral development process, which is described on page ES-7 of the PEIS, allows MDA to "consider deployment of a missile defense system that has no specified final architecture and no set of operational requirements." Such a process is apparently intended to preclude any meaningful assessment, and thus far it has succeeded brilliantly, to the detriment of the public interest, the national defense of the United States, and in frustration of the purpose of requiring careful NEPA analysis of major federal actions.	While the Executive Summary does provide a brief summary of the "spiral development process" Section 2.1.3 of the PEIS provides a more detailed look at the MDA's current acquisition approach. This approach allows the MDA to be more flexible in adapting to emerging threats leading to a more successful defensive system. This approach is not intended to nor does it "preclude any meaningful assessment" of the system or its environmental impacts. The MDA will continue to inform and involve the public in the NEPA process for future tiered analyses that are applicable to the BMDS.
NEPA Process	F0006-2	Based on the information provided in the draft PEIS, NOAA Fisheries recommends that the Missile Defense Agency consult with the appropriate NOAA Fisheries Regional Office to determine if listed species under the	On January 14, 2004 MDA representatives met with NOAA Fisheries Service personnel to discuss programmatic consultation pertaining to the BMDS PEIS. If site-specific analyses indicate that BMDS

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

		Endangered Species Act (ESA) of 1973 as amended (16.U.S.C. 1531 et. seq.) may be affected by the proposed project. If it is determined that this project may affect a listed or proposed species, the Missile Defense Agency should request initiation of consultation with NOAA Fisheries pursuant to section 7 of the ESA.	activities may affect species listed under the Endangered Species Act of 1973, the MDA will request consultation with the relevant NOAA Fisheries Service Regional Office, as appropriate.
NEPA Process	PHO0011-8	The effects of war are not excluded for the analysis of NEPA.	The interceptors would only be launched in defense of the nation in the event of a ballistic missile attack. The environmental impacts of wartime operations are highly speculative and are not susceptible to meaningful analysis in an EIS. In addition, the effects of war are excluded from analysis under NEPA.
NEPA Process	PHO0048-8	They are using this process to sort of tell people who don't think we have the time to get involved because we're too busy being employed and trying to raise a family, they use this process to cover up the fact that we aren't really making an informed decision, that people are being taken advantage of, and the law is being tweaked and used to their advantage to disempower us. So although they may meet technical requirements of NEPA, we need to make people aware of the fact that they are not meeting the real requirements of NEPA and we aren't making an informed decision. Thank you.	The MDA has made extensive efforts to ensure that the public had adequate opportunity to review and comment on this PEIS. In addition to the public hearings, the MDA developed a publicly accessible web site to provide information on the BMDS PEIS and request comments on the Draft PEIS. The MDA also established toll-free phone and fax lines, an e-mail address, and a U.S. postal service mailbox for submittal of comments and questions. Both the Notice of Availability (NOA) of the Draft PEIS published in the Federal Register (FR) and the BMDS PEIS web site provided instructions on submitting comments on the Draft PEIS. Comments received via any of the methods identified carry exactly the same weight as comments provided orally or in written format to MDA during a public hearing. This PEIS is being prepared to address the potential environmental impacts of alternatives for implementing the proposed BMDS. The PEIS is a resource to help

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
			MDA decision makers determine the environmental impacts of implementing the BMDS as an integrated system. The MDA has fulfilled the requirements of NEPA and has encouraged public participation throughout this process.
NEPA Process	PHO0051-5	The second thing that I would like to talk bout is five minutes. How long did it take you to put this study together? You all only give us five minutes to comment. I don't understand that.	In addition to the public hearings, the MDA developed a publicly accessible web site to provide information on the BMDS PEIS and request comments on the Draft PEIS. The MDA also established toll-free phone and fax lines, an e-mail address, and a U.S. postal service mailbox for submittal of comments and questions. Both the NOA of the Draft PEIS published in the FR and the BMDS PEIS web site provided instructions on submitting comments on the Draft PEIS. Comments received via any of the methods identified carry exactly the same weight as comments provided orally or in written format to MDA during a public hearing. As explained during the public hearing the five minute time limit was provided to ensure that all participants had the opportunity to provide their comments. After all participants had an opportunity to speak for up to five minutes, any commenter who wished to provide additional oral comment was invited to do so.
NEPA Process	PHW0001-1	Here, MDA has ignored the highly controversial nature of the missile defense program; has, over the years, issued a series of separate environmental analyses on smaller parts of the entire system, so as to avoid the cumulative impact test, and the nature of the proposed layered integrated BMDS program described in this PEIS is so substantially different from earlier iterations that any reliance on many	This PEIS is being prepared to address the potential impacts of implementation alternatives for the proposed BMDS. As described in Section 2.1.3 of the PEIS, the system acquisition process historically has focused on the development of independent stand-alone defensive elements. Consistent with this approach, the MDA developed NEPA analysis that appropriately considered

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		of those earlier environmental analyses is misplaced. They simply will not pass muster. And, as the Ninth Circuit instructed another agency in a case involving a controversial proposal, "... the term 'controversial' refers to cases where a substantial dispute exists as to (the) size, nature, or effect of the major federal action rather than to the existence of opposition to a use. Foundation for North American Wild Sheep v. United States Department of Agriculture, 681 F 2d 1172(9th Cir.1982).	the impacts of these stand-alone systems. The MDA is now working to incrementally develop and field a BMDS that layers and integrates defenses to intercept ballistic missiles in all ranges of flight. Therefore, it is now appropriate for the MDA to prepare a PEIS which discusses the environmental impacts of such a proposed system. Future site-specific analyses necessary to support proposes tests or new developments of the BMDS will tier from this PEIS. Both this PEIS and future analyses consider cumulative impacts, as appropriate.
NEPA Process	PHW0002-7	Another issue that is raised and not explored fully is the testing and deployment of missile defense systems abroad, or OCONUS as it is referred to here. The document asserts, "MDA may also develop test beds in other areas such as the Atlantic Ocean, Gulf of Mexico, or outside the continental U.S. to support testing of BMDS components in those areas." (p. 2-28) But it does not say how this would occur, only that "Because NEPA and other environmental laws generally do not apply to OCONUS activities, various EOs and other DoD directives and instructions have been implemented." (p. 4-111) However, nothing specific has been given on how these laws were implemented; rather, the draft PEIS directs the reader to Appendix G, which is a long listing of international treaties and does not explicitly state how the missile defense systems fit into these commitments. Given how unpopular missile defense is amongst the Canadian, British, and Greenlandic publics - the three countries that are the nearest to being incorporated into the BMDS - this should be explained further.	The PEIS considers the potential impacts of BMDS activities on multiple biomes where the BMDS could be implemented. The PEIS is not site-specific and therefore does not consider specific treaties or agreements that would apply at particular sites where the BMDS could be implemented. If specific activities are proposed in locations outside the continental U.S. (OCONUS) including Canada, United Kingdom, and Greenland, the MDA would work with the appropriate authorities to ensure that all applicable requirements are met.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

NEPA Process	PHW0009-1	1) The PEIS appears to be biased towards minimizing the environmental impact of the BMDS. There is an inherent conflict of interest win this report being written by the MDA, which has a stake in the BMDS project proceeding. An independent environmental impact report should be commissions by a nonpartisan panel of scientists with expertise in the field.	Instruction 4715.9, Environmental Planning and Analysis, Presidential EO 12114, Environmental Effects Abroad of Major Federal Actions, and applicable DoD military service environmental regulations that implement these laws and regulations. Section 1506.5(c) of the CEQ NEPA Regulations outlines the lead agency's responsibility with respect to preparing an EIS. This Section states that "…any environmental impact requirements of NEPA shall be prepared directly by or by a contractor selected by the lead agency…" Therefore, the PEIS was prepared appropriately as directed by the CEQ guidelines.
No Action Alternative	E0158-1	I can't support anything but a True "NO ACTION".	As noted in CEQ's "Forty Most Asked Questions", there are two interpretations of the No Action Alternative depending on the nature of the proposal being evaluated. In situations where "no action" is illustrated in instances involving Federal decisions on proposals for project "no action" would mean the proposed activity would not take place. In situations that involve an action such as updating a land management plan where ongoing programs initiated under existing legislation and regulations will continue, even as new plans are developed, "no action" may be thought of in terms of continuing with the present course of action until that action is changed. It is further noted that to construct an alternative based on no management at all would be a useless academic exercise. For this PEIS, because the proposed action involves the integration of existing discrete missile defense systems, the no action alternative would be to continue with existing stand-alone systems; not to scrap all existing systems like the

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
			PATRIOT missile already in use in theater defense by U.S. forces.
No Action Alternative	E0162-2	Another major general deficiency is that the No Action alternative is not considered seriously. It is asserted on page 2-67 that it "would not meet the purpose of or need for the proposed action or the specific direction of the President and the U.S. Congress." Footnote.19 on page 1-6 quotes the part of the 1999 Missile Defense Act which declares a policy to "deploy as soon as is technologically possible an effective NMD system." It is noted on page 1-6 that Pres. Clinton decided in Sept. 2000 not to authorize deployment of an NMD system for reasons including technical uncertainties and unsuccessful flight tests. Two GAO reports in 2003 and a Union of Concerned Scientists report Technical Realities in May 2004 raise serious questions about the readiness for deployment of current NMD components. Therefore, it seems that the No Action alternative (which was essentially U.S. policy until 2002) is preferable until one can demonstrate that an "effective" NMD is "technologically possible." The most recent NMD intercept attempt failed on 11 Dec. 2002, six days before Pres. Bush announced that the U.S. would deploy an initial NMD system. The test results so far and independent analyses suggest that it is at least questionable whether an effective NMD system is possible.	See previous response.
No Action Alternative	E0179-1	I believe that halting the project is the best option.	See previous response.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
No Action Alternative	E0186-1	To continue on with this project as would be the case even under the "no action alternative" is unconscionable. We believe that even if you were to re-do the PEIS, there would be no reasonable alternative other than shutting down the project and calling it the loss it already is.	See previous response.
No Action Alternative	E0204-1	It is my understanding that Alternative 3 means "no change" so that all programs continue as planned. This is not acceptable. The statement must be rewritten to allow for a true "no action" choice....meaning NO R&D or Production of the missile defense program, no weapons in space!	See previous response.
No Action Alternative	E0211-1	The PEIS must be rewritten, because the "No action" alternative is insufficient. The most appropriate choice is to stop all funding of Star Wars Missile defense.	See previous response.
No Action Alternative	E0211-2	I want no more of my tax dollars to support this foolish program. Please rewrite the PEIS to allow the sanest alternative- scrapping this program entirely- to be a choice. The best choice.	See previous response.
No Action Alternative	E0216-1	For all these reasons I believe the "No Action Alternative" is insufficient and the entire PEIS should be rewritten.	See previous response.
No Action Alternative	E0231-1	The definition of no action to me is to STOP WHAT IS NOW BEING DONE!!!	See previous response.
No Action Alternative	E0233-1	None of the three options for PEIS is acceptable! The third is the most dangerous because it is so deceptive, meaning "business as usual." Let's scrap this entire frivilous program and get on with the vital business of remediation of the mistakes of the past four years and prevention of more of the same during the second Bush administration.	See previous response.
No Action Alternative	E0262-1	I am writing in opposition to the three options of the MDA BMDS PEIS, including the No Action option, since it is in	See previous response.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		reality not a true No Action as it includes continued development of interceptors. I urge you to revise these options with more concern for the environmental damages that will result from these actions.	
No Action Alternative	E0270-1	The"No Action Alternative" is insufficient and the entire PEIS should be rewritten. No nukes in space!!!!!!	See previous response.
No Action Alternative	E0319-27	Regarding the BMDS Draft PEIS and No Action Alternative, the MDA comments: "This alternative would not meet the purpose of or need for the proposed action or the specific direction of the President and the U.S. Congress to defend the U.S. against ballistic missile attack". Perhaps the PEIS could explain exactly what the President and Congress have proposed for the BMDS, because the MDA evidently does not know 'the specifics of the final architecture or operational requirements' otherwise, the information would have been included in the Draft PEIS, so the public would have an Alternative 3 option to comment on that did not include 'exploding' missiles in space or firing space-based lasers at ground targets, which eventually will lead to the U.S. Department of Defense's control of space by the year 2020 (U.S. Air Force, Vision 2020).	See previous response.
No Action Alternative	E0332-1	1. The three alternatives being considered are insufficient and deceptive. "No Action" is an endorsement of the current ABM program which is badly flawed and which should be terminated. The PEIS as it is being conducted does not meet congressional requirements and must be started over with real alternatives.	See previous response.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
No Action Alternative	E0343-1	I am writing to support a real "No Action" alternative to the deployment of a missile defense system. This means no further testing, development, or deployment.	See previous response.
No Action Alternative	E0355-1	Alternative 3, "No Action," which might seem like a logical out for those wanting to suppress this race to destruction, seems to leave things as they are - i.e. would allow continuation of the present programs which we are against! So the PEIS should be rewritten to allow another alternative: Discontinue all work on such systems, and work on getting cooperation throughout the world on disarmament.	See previous response.
No Action Alternative	E0366-1	(5) For all of the above, and many more, we believe that the only acceptable alternative is for NO BALLISTIC MISSILE SYSTEM AS OUTLINED IN THIS PEIS. Note that does not mean the vno action alternative' IT MEANS NO PROGRAM.	See previous response.
No Action Alternative	E0373-1	Since it appears that "no action" in this context means "carry on with the plan", the three alternatives being considered by PEIS are all unacceptable.	See previous response.
No Action Alternative	E0387-6	Yorkshire CND asks that our concerns be taken seriously and considered properly. The PEIS has offered itself three options, none of which is sufficient. As we understand it, the "no action" option simply allows for no change in current developments and the continuation of the project. If this is to be the ultimate step that the MDA is prepared to take then it implies a bias towards the outcome of this PEIS study by not allowing for the possibility that the Missile Defence system is too environmentally destructive to continue with.	See previous response.
No Action Alternative	E0395-4	What is called the "No Action Alternative" is not adequate under NEPA and does not describe a scenario where no	See previous response.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		action is taken. Rather it describes a situation where the Missile Defense Agency would continue existing development and deployment of missile defense systems unabated. Under the "No Action Alternative" individual systems would continue to be tested and deployed except for integrated system-wide tests. This is hardly no action and would permit an indeterminate missile defense program, especially since, as explained in the draft, "There are currently no final or fixed architectures and set of requirements for the proposed BMDS." Even if MDA agreed to the "No Action Alternative," it would not find its actions constrained for the foreseeable future. The MDA needs to develop new alternatives which meet the intent of NEPA.	
No Action Alternative	E0395-5	Most crucially, the "No Action Alternative" strangely links world events, policy objectives with environmental considerations; unprecedented in an environmental document which is supposed to be grounded in the science of risk assessment. The PEIS reads: "The decision not to deploy a fully integrated BMDS could result in the inability to respond to a ballistic missile attack on the U.S. or its deployed forces, allies, or friends in a timely and successful manner. Further, this alternative would not meet the purpose of or need for the proposed action or the specific direction of the President and the U.S. Congress." Through the MDA's own volition, the document goes beyond environmental considerations and opens a Pandora's Box of analyzing the state of American security,	See previous response.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		the potential for missile attack, and the appropriate policy responses. Therefore, it is now MDA's responsibility to respond to all public comment on threat and policy, even those challenging the rationale for missile defenses. Now that the Pandora's Box is open on policy, the Missile Defense Agency should, for example, make the case that nuclear deterrents no longer suffice, and MDA should substantiate why BMDS is the preferable security strategy over other Alternatives by which America might be kept safe, such as through United Nations IAEA inspections, international controls on missile sales and missile technology, or diplomacy.	
No Action Alternative	E0395-6	If the agency choices to maintain the current "No Action Alterative" - which we do not support - the final PEIS would need to offer a realistic analysis (and timeline) of missile threats against the American homeland, nor fudge the distinction between theater and strategic threats. Further, the "No Action Alternative" would eliminate systems integration testing, the very testing that would be needed to demonstrate that a layered missile defense system, as ordered by the President, can work. Elsewhere in this PEIS the President's direction is cited as a reason why no further change in the plan is being considered, but in the "No Action Alternative," the President's direction is clearly negotiable.	See previous response.
No Action Alternative	E0402-1	I think the most important issue is that the BMDS PEIS does not contain a real No Action Alternative. Your No Action alternative which many people think is a good option really only states that the entire plan be	See previous response.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		implemented as already underway with only the exclusion of the new layered additions. A real No Action alternative, stops the implementation of the nuclear missile defense system.	
No Action Alternative	E0402-3	Therefore, given the potential severe environmental damage from both testing and deployment of this program, a true no action policy is preferable.	See previous response.
No Action Alternative	E0423-1	Now for the larger picture. The BMDS PEIS does not include a real "No Action Alternative" of not developing ballistic missile defenses, Like a number of medical treatments, from bleeding people hundreds of years ago to Viox a month ago, the remedy is worse than doing nothing.	See previous response.
No Action Alternative	E0424-3	4) The BMDS PEIS does not include a real "No Action Alternative". Such an alternative that does not include further development testing or deployment of BMDS weapon systems needs to be considered and included in the PEIS. Such a "No Action Alternative" would include strong support for efforts by the UN and nations around the world to enhance security through strengthening inspection and verification protocols of existing treaties, and by re-commitment to arms control and disarmament approaches that to date have served to limit global Weapons of Mass Destruction (WMD) proliferation. As such, the PEIS needs to consider explicitly whether the BMDS would itself encourage the proliferation of WMD, as well as an arms race in space, with examination of the likely response of other nations to the BMDS. As the BMDS is coupled to continued U.S. nuclear weapons	See previous response.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		programs, will this lead other nations horizontally proliferate for "deterrence" capabilities?	
No Action Alternative	E0427-1	3) The BMDS PEIS does not include a real "No Action Alternative". Such an alternative that does not include further development testing or deployment of these weapon systems needs to be considered and included in the PEIS. The BMDS PEIS has not considered the "No action Alternative" of re-joining the UN and many nations of the world in working to enhance security through treaties and arms control and disarmament approaches, e.g. the approach that has provided us with long-term security to date.	See previous response.
No Action Alternative	E0429-1	Furthermore, the PEIS lacks a genuine "No Action Alternative," even though NEPA requires that such an alternative serve a baseline against which to compare the environmental impacts of the other alternatives. In particular, a No Action Alternative that posits little or no use of rocket propellant is essential if the program's proponents are to minimize releases of pollutants - particularly solid rocket propellant and its byproducts into our nation's water supplies, air, or the upper atmosphere, either by selecting a program alternative or agreeing to binding mitigation measures.	See previous response.
No Action Alternative	E0429-8	The PEIS lacks a genuine, "No Action Alternative," as required under NEPA. It rejects evaluation of the alternative, "Cancel Development of Ballistic Missile Defense Capabilities," because it "does not meet the purpose of or need for the proposed action ..." (page 2-68). This approach misunderstands how NEPA works. It is acceptable to evaluate and reject a No Action Alternative because it doesn't meet the purpose of a program, but the	See previous response.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		environmental impacts of that alternative must be considered as a baseline against which to compare the environmental impacts of the other alternatives. In particular, a No Action Alternative that posits little or no use of rocket propellant is essential if the program's proponents are to minimize releases of pollutants into our nation's water supplies, air, or the upper atmosphere, either by selecting a program alternative or agreeing to binding mitigation measures.	
No Action Alternative	E0439-1	3) The BMDS PEIS does not include a real "No Action Alternative". Such an alternative that does not include further development testing or deployment of these weapon systems needs to be considered and included in the PEIS. The BMDS PEIS has not considered the "No action Alternative" of re-joining the UN and many nations of the world in working to enhance security through treaties and arms control and disarmament approaches, e.g. the approach that has provided us with long-term security to date.	See previous response.
No Action Alternative	F0005-3	Another major deficiency of the draft PEIS is that it lacks a genuine "No Action Alternative", even though NEPA explicitly requires that such an alternative serve as a baseline against which to compare the environmental impacts of the other alternatives. LAWS is compelled to conclude that the MDA simply did not consider a "No Action Alternative" seriously. For example, the MDA asserts on page 2-67 that "it would not meet the purpose of or need for the proposed action or the specific direction of the President and the U. S. Congress." Further, footnote 19 on page 1-6 quotes the part of the 1999 Missile Defense	See previous response.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		Act which declares the policy "to deploy as soon as is technologically possible an effective NMD system." The PEIS also notes on page 1-6 that President Clinton decided in September 2000 not to authorize deployment of an NMD system for reasons including technical uncertainties and unsuccessful flight tests. The PEIS does not concede that even if the technology worked perfectly, the systems being deployed are vulnerable to counter-measures that are easier to build than the long-range missile on which they would be placed, another concern that contributed to President Clinton's decision not to deploy the system the Bush Administration is now rushing to deploy.	
No Action Alternative	F0005-4	In addition, two GAO reports in 2003 and a Union of Concerned Scientists report titled 'Technical Realities" released in May, 2004 raise further serious questions about the readiness for deployment of the current NMD components. It seems clear to LAWS that a properly-articulated "No Action Alternative"-which was essentially U.S. policy until 2002 - is vastly preferable until the MDA can persuasively demonstrate that an "effective" NMD is "technologically possible." Recent test results underscore this reality. The most recent NMD intercept attempt failed on December 11, 2002, six days before President Bush announced that the U. S. would deploy an initial NMD system. This rush to deploy an untested system flies in the face of the test results so far, and suggests that the independent analyses that state that it is at least questionable whether an effective NMD system is possible, have been ignored. The policy stakes are far too	See previous response.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		high, and the $10 billion annual expenditures far too great, to proceed with this global gamble.	
No Action Alternative	F0005-5	The width of the range of alternatives that an agency must identify and analyze in an EIS is based on the purpose of, and need for, the agency action. (See 40 C.FR: Sec. 1502.13,1502.14.) Therefore, a narrow project purpose and need requires a fewer number of reasonable alternatives than a broad project purpose and need, which may have an infinite number of alternatives. (See NRDC v. Morton, 458 F.2d 827, 835; D.C. Cir. 1972)	See previous response.
No Action Alternative	F0005-10	As pointed out above, instead of crafting the PEIS to justify decisions that have already been made, the MDA should have included a genuine "No Action Alternative", as required under NEPA. Such an alternative could have been "Cancel Development of Ballistic Missile Defense Capabilities" because it does not meet the purpose of or need for the proposed action. It is acceptable under NEPA to evaluate and reject a No Action Alternative because it doesn't meet the purpose of a program, but the environmental impacts of that alternative must be considered as a baseline against which to compare the environmental impacts of title other alternatives.	See previous response.
No Action Alternative	M0234-1	The NO ACTION alternative is the only acceptable option, but one in which there would be NO FURTHER RESEARCH OR DEVELOPMENT of "Missile Defense" systems or "Space Based Weapons."	See previous response.
No Action Alternative	M0234-2	So our basic conclusion would be that a NO ACTION alternative, that truly means NO ACTION, cutting off all funding for any further development of BMDS or sub-systems of it.	See previous response.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
No Action Alternative	M0262-1	For all these reasons, I support ending all work on the Missile Defense system. None of the alternatives presented in your Draft Programmatic Environmental Impact Statement includes ending the program. Therefore, I call on you to rewrite and resubmit the PEIS for public comment, including another alternative: ending the Missile Defense System.	See previous response.
No Action Alternative	M0266-1	The existing text for Alternative 3 is not a NO ACTION alternative. The MDA itself rejects it as an inadequate version of the first two alternatives presented.	See previous response.
No Action Alternative	M0266-2	1). Beginning in January 2005 the current Ballistic Missile Defense Program (BMD) would be suspended immediately and in entirety, or a moratorium on deployment, research and development would be declared while a thorough investigation of the program occurs. Congress, the Administration, auditors, scientists, aerospace engineers and the general public would participate in a thorough reconsideration of the costs, workability and desirability of this program in all its aspects.	See previous response.
No Action Alternative	M0274-1	I believe the "no action" alternative is an insufficient brake to further Star Wars developments. I strongly urge a intensive rewriting of PEIS.	See previous response.
No Action Alternative	PHO0007-1	This proposal that we're asked to address tonight does not contain a real No Option Alternative not to build the system, to abandon it. That is what I think most of the people in the United States and the world would affirm.	See previous response.
No Action Alternative	PHO0009-2	The second thing is the PEIS does not evaluate the environmental impact of No Action Alternative; thus, does not comply to the National Environmental Policy Act.	See previous response.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
No Action Alternative	PHO0009-3	The report -- since No Action Alternative was not considered seriously in the impact report, I say it is not an impact report at all. Therefore, it has not complied with the legal requirements; therefore, it should be stopped. Thank you.	See previous response.
No Action Alternative	PHO0011-6	The BMDS does not include a real No Action Alternative. Such an alternative does not include further development and testing and deployment of these weapon systems needs to be considered and included in the PEIS. The PEIS does not consider a No Action Alternative at all. In other words, something that would involve rejoining the UN and -- and many other nations of the world in order to enhance security through treaties and arms control, sovereign approaches; i.e., approaches that provided us with long-term security to date.	See previous response.
No Action Alternative	PHO0013-1	And I suggest an Alternative Number 4, which means scrap the entire PEIS and the whole program that they are presenting here.	See previous response.
No Action Alternative	PHO0018-1	First, I call for a true No Action Alternative, as have others. For example, or specifically, an alternative that goes beyond the failure to integrate anti-ballistic missile system to an alternative that rejects the individual missile defense elements of a BMD System.	See previous response.
No Action Alternative	PHO0018-2	Because of the devastating impacts -- political, environmental, ecological and psychological, as well as merely environmental -- the impacts of a Ballistic Missile Defense Program of any kind, this PEIS must address a true No Action Alternative. The failure of this PEIS to include such a true No Action Alternative violates the requirements of the NEPA process. The absence of a true No Action Alternative allows the PEIS to construct a false	See previous response.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		comparison with the other alternatives underplaying the different degrees of environmental damage.	
No Action Alternative	PHO0019-1	You have no true No Action Alternative; only build it together or build it a little bit at a time and don't test it together.	See previous response.
No Action Alternative	PHO0019-2	What you should do in your own terms is to consider a true No Action Alternative, which is an analysis of the relative emissions of greenhouse gasses and space debris and toxic chemicals and radiation caused by either (A), blowing things up or (B), pursuing broader implementations of existing treaties, such as the Nuclear Non-proliferation Treaty and the Anti-Ballistic Missile Treaty, which would not produce any greenhouse gasses, any space debris and would not blind any animal or destroy any life on Earth. Thank you.	See previous response.
No Action Alternative	PHO0024-1	This is reason enough for the No Project Alternative CEQ style.	See previous response.
No Action Alternative	PHO0026-2	With respect to the No Action Alternative already mentioned by others, it does not describe a scenario where no action is taken. Rather, it describes a system where the Missile Defense Agency would continue existing development and deployment unabated under the No Action Alternative. And I quote the PEIS here, Individual systems would continue to be tested but would not be subjected to system integration tests, closed quotes. This is hardly no action and allows for indeterminate missile defense program since -- to go back to quoting the PEIS, There are currently no final fixed architectures and no set operational requirements for the proposed BMDS, closed quotes.	See previous response.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
No Action Alternative	PHO0032-2	We would support the No Action Alternative if there had been a legitimate attempt at researching and weighing a true alternative of no action. Such a proposal should have encompassed a suspension of research and development, no testing and no initial deployment. It should have evaluated the cost effectiveness of vigorous pursuit of international cooperation on nuclear disarmament. As it stands, the No Action Alternative does not meet the requirements of the National Environmental Policy Act. For this reason, we consider the Draft PEIS inadequate and insufficient for proceeding with the BMDS.	See previous response.
No Action Alternative	PHO0037-6	And, last, the BMDS PEIS does not really include a No Action Alternative. Your No Action Alternative does not include the option of not deploying any of these, there's just dropping the program right now. And I think that we need to have a true No Action Alternative considered as part of this.	See previous response.
No Action Alternative	PHO0038-1	I, like Jean, am in favor of the No Action Alternative, but would also like a real No Action Alternative, which would save us tens to hundreds of billions of dollars if we didn't deploy the system.	See previous response.
No Action Alternative	PHO0039-1	I'd like to see something quite a bit less than the No Action Alternative, I'd really like to see something rolled back in a way and dismantling and using these resources, the financial resources that were wasted on this on much more pressing needs in this country.	See previous response.
No Action Alternative	PHO0044-6	The No Action Alternative is not seriously considered. It is claimed not to be at the direction of Congress, presumably the 1999 Missile Defense Act. This Act states	See previous response.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		U.S. policy is to deploy as soon as is technologically possible an effective NMD system, but the EIS has no discussion about NMD effectiveness and whether that criteria is satisfied.	
No Action Alternative	PHO0045-1	We support a real No Action Alternative to the deployment of a missiles defense system. This means no further testing, development or deployment.	See previous response.
No Action Alternative	PHO0046-1	I think that you have inadequate alternatives. You only have three alternatives and there ought to be a fourth one which includes not deploying, developing the Ballistic Missile Defense System, and actually reducing the scope of existing programs.	See previous response.
No Action Alternative	PHO0048-3	NEPA requires the alternatives to be considered, including the No Action Alternative, as has already been stated.	See previous response.
No Action Alternative	PHO0048-5	And the reason for this, the reason why this is justified is because they're getting off on a technicality, because they stated that the purpose of this program or this project is to implement a Ballistic Missile Defense System. It's misleading, because really what this project is supposed to do, like the overriding principle, is to provide for the defense of the United States.	See previous response.
No Action Alternative	PHO0049-2	Then, finally, I wanted to say that in your EIS I think you're misleading all of us by putting No Action as a third alternative. I think you need to be more honest and state specifically that No Action means to keep on testing as is without the integration.	See previous response.
No Action Alternative	PHO0049-3	I think that some of the people here felt like No Action meant that you were going to start dismantling the missile defense system, which, of course, should have been stated as another alternative, which you didn't even give us a chance to put down.	See previous response.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
No Action Alternative	PHO0049-4	And please give us another alternative which says stop Star Wars, dismantle the missile defense system, start helping the people who really need the help, and let's bring peace instead of more destruction.	See previous response.
No Action Alternative	PHW0001-5	The PEIS is defective to the extent that it fails to meet the CEQ guidance on the range of alternatives agencies must consider. Here, the MDA has failed to propose a real no action alternative, and the so-called no action alternative set out at PEIS 2-67 is not a true no action alternative because under it all the individual components of the system would continue to be tested to determine the adequacy of their stand-alone capabilities. Such an alternative could easily have been Alternative 3, but the MDA should also have clearly set out a real no action alternative so that the public could comment on it, instead of being caught in the Catch-22 this PEIS poses. It is difficult not to conclude that the agency's choice of alternatives was dictated by the end result it desired. While there may be portions of the CEQ guidance where reasonable people may differ, surely this is not one of them. And LAWS submits that a reviewing court would find the range of alternatives set out in the PEIS inadequate, in view of all the circumstances.	See previous response.
No Action Alternative	PHW0002-1	To begin with, the so-called "No-action alternative" examined in this document is misleadingly named. It does not detail a scenario where no action is taken. Rather, it describes a system where "the MDA [Missile Defense Agency] would continue existing development and testing of discrete systems as stand-alone missile defense capabilities. Individual systems would continue to be tested but would not be subjected to system integration	See previous response.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		tests." (p. ES-8) This is hardly no action and allows for an indeterminate amount of missile defense development, since "There are currently no final or fixed architectures and no set operational requirements for the proposed BMDS." (p. 1-9) The way this draft PEIS is structured, even if MDA was limited to the No-action alternative, it would not find its actions very much constrained.	
No Action Alternative	PHW0004-1	Furthermore, the PEIS lacks a genuine "No Action Alternative," even though NEPA requires that such an alternative serve a baseline against which to compare the environmental im¬pacts of the other alternatives. In particular, a No Action Alternative that posits little or no use of rocket propellant is essential if the program's proponents are to minimize releases of pollutants-particularly solid rocket propellant and its byproducts-into our nation's water supplies, air, or the upper atmosphere, either by selecting a program alternative or agreeing to binding mitigation measures.	See previous response.
No Action Alternative	PHW0004-8	The PEIS lacks a genuine, "No Action Alternative," as required under NEPA. It rejects evaluation of the alternative, "Cancel Development of Ballistic Missile Defense Capabilities," because it "does not meet the purpose of or need for the proposed action ..." (page 2-68). This approach misunderstands how NEPA works. It is acceptable to evaluate and reject a No Action Alternative because it doesn't meet the purpose of a program, but the environmental impacts of that alternative must be considered as a baseline against which to compare the environmental impacts of the other alternatives.	See previous response.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		In particular, a No Action Alternative that posits little or no use of rocket propellant is essential if the program's proponents are to minimize releases of pollutants into our nation's water supplies, air, or the upper atmosphere, either by selecting a program alternative or agreeing to binding mitigation measures.	
No Action Alternative	PHW0005-2	We would support the "No Action Alternative," if there had been a legitimate attempt at researching and weighing a true alternative of "no action/' Such a proposal should have encompassed a suspension of research and development, no testing, and no initial deployment. It should have evaluated the cost-effectiveness of vigorous pursuit of international cooperation on nuclear disarmament. As it stands, the "No Action Alternative" does not meet the requirements of the National Environmental Policy Act. For this reason, we consider this draft PEIS inadequate and insufficient for proceeding with the BMDS.	See previous response.
No Action Alternative	PHW0006-2	2. The PEIS does not evaluate the environmental impact of the no action alternative, and thus does not comply with the intent of the National Environmental Policy Act. Without this evaluation there is no way to compare the environmental impact of the program to the impact of the no action alternative, and thus violates both the letter and the spirit of NEPA.	See previous response.
No Action Alternative	PHW0009-2	4) The "No Action Alternative" is not fairly presented or considered. The alternative of the worldwide elimination of ICBM's through diplomatic means and international cooperation, including worldwide imposition of UN arms inspections.	See previous response.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
Procedural	E0319-28	Most likely, Volume 1 of the BMDS PEIS has already been printed and the MDA is waiting to receive and include public comments before releasing it and publicly announcing to the news media that the BMDS is 'deployed'.	MDA considered all comments received during the public comment period and made changes to the document as appropriate. Any modifications based on comments are outlined in this appendix.
Procedural	E0395-3	The timeline to release the Final PEIS - cited on the MDA web-site and announced at the October 19, 2004 public meeting - a mere two to six weeks after the comment period deadline portends that MDA will not fully consider and respond to public testimony. PSR-LA emphatically suggests that MDA take the time to consider and respond in full to all comments and critiques.	Based on the number of comments received, MDA extended the original release date of the Final PEIS in order to adequately consider public comments.
Procedural	PHO0023-1	Most notably, I would like to point out that the timeline of potentially releasing the final document but two weeks after the oral testimony, as well as what anyone else could offer in writing and -- or even six weeks later into -- in the end of January of '05 strikes me that you very well may not take too seriously what we have to say. I would strongly suggest that you factor a time when you can actually take into account the things that the public are suggesting.	See previous response.
Procedural	PHW0001-7	As LAWS and PSR pointed out in their Vandenberg EA comments, "The issues are too important, and the priority accorded this program would suggest to a reviewing court that rather than risk extended delays inherent in legal challenges to the sufficiency of this (PEIS), the MDA would be well advised to take the time and make the effort to prepare a comprehensive (PEIS) that fully meets all the legal requirements of NEPA." That is still good advice. While the PEIS is an improvement in some respects, it remains fatally flawed. LAWS and PSR and others will	See previous response.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		spell out these fatal flaws in the written comments that are due November 17, 2004.	
Procedural	PHO0037-1	Three, NEPA does not seem, to me, to be a big enough vehicle to evaluate the program. It should include international input because the implications of this project are global. And I noticed on your map out there Antarctica is not included on the map. I'm sure you looked at it but.....	The PEIS addressed the international scope of the BMDS program by describing world environments in terms of global biomes. Appendix G also discusses compliance with applicable international environmental and safety regulations. Antarctica was not included on the map or in the analysis because there are no reasonably foreseeable BMDS actions proposed to take place in Antarctica. If there were future BMDS activities proposed in this area, they would be addressed in site-specific environmental documentation.
Procedural	PHO0051-6	The other thing is, and people have already commented that you don't have any person here that can translate our language.	Attendees at the public hearing were given the opportunity to provide testimony in both Hawaiian and Marshallese languages. A court reporter recorded the proceedings and the audiotapes were later translated by certified translators. Transcripts from the hearings, including the translated Marshallese and Hawaiian oral testimony, can be found in Appendix B of this PEIS.
Procedural	PHO0055-1	KELI'I COLLIER: Okay. Not much. So when you say that you weigh the written testimony as heavy as the oral testimony, that premise alone is a fault of yours, it's a fault of your thinking, it's a fault of your understanding of where you are, this context of Hawaii. These people can barely feed themselves half the time. They can barely send their kids to school with slippers. So that's something you got to wake up to fast.	Approximately 8,500 comment documents were received on the Draft BMDS PEIS. Comments received via any of the methods identified carry exactly the same weight as comments provided to MDA orally during a public hearing.
Proposed Action	E0347-3	The long-established US satellite-surveillance downlink and relay Bases, such as Menwith Hill and Pine Gap,	The proposed action analyzed in this PEIS includes analysis of various components that could be integrated

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		positioned around the world for the purpose of intelligence gathering, are necessary components of the US Missile Defense System, as they would be used to monitor in advance, the preparations for the launch of a rocket. These facilities comprise part of the US Missile Defence system package and exclusion from the US Missile Defence Agency's Programmatic Environmental Impact Statement deliberations cannot be justified.	into the BMDS. The PEIS analyzes components rather than elements because the MDA acquisition strategy has changed significantly as described in Section 3.1.2 of the PEIS. The components of the various elements deployed at locations around the world are analyzed as part of this PEIS.
Proposed Action	PHO0046-6	So I say that that needs to be considered. The opportunity costs of ballistic missile defense is one of the impacts that we have to deal with and our children have to deal with, and it needs to be considered in your Environmental Impact Statement, and I didn't see it listed there.	This PEIS is being prepared to consider and analyze the potential environmental impacts of alternatives for implementing the proposed BMDS. The PEIS is a resource to help MDA decision makers determine the environmental impacts of implementing the BMDS as an integrated system. Cost associated with system development and testing is addressed by the Congress during the budgeting process and is not relevant to this environmental analysis.
Public Involvement	E0319-1	The MDA did a very poor public relations job in regard to getting the word out on the availability of the Draft PEIS and on the October 2004 public hearings in what will be the affected BMDS test communities. The public cannot make comments on something they do not know exists if it is not well advertised in advance (e.g. notices in newspapers). Holding public hearings in Anchorage, Alaska when the BMDS test site is located on Kodiak Island, Alaska, and in Sacramento, California when the test site is at Vandenberg AFB near Los Angeles, showed the MDA's intent was to make it as difficult as possible for members of the public to travel to the meeting places to testify and give their comments on the Draft PEIS. The MDA put a public notice in the Kodiak Daily Mirror and	The PEIS is a programmatic level NEPA analysis that considers implementation alternatives for an integrated BMDS and as such does not address specific sites or specific activities at those sites, but rather considers the program as a whole to allow tiering of subsequent site-specific analyses from the PEIS. MDA planned to hold its public hearings on the Draft PEIS in the same locations at which scoping meetings were held. Notification of the BMDS PEIS scoping meetings was published in the Kodiak Daily Mirror on April 30, 2003 and May 2, 2003 and notification of the BMDS PEIS public hearings was published in the Kodiak Daily Mirror on October 13, 2004 and October 15, 2004. A

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		sent a copy of the Draft PEIS to the Kodiak Island Borough's office only after being urged by local residents. Otherwise, local officials and community members would not have known of its existence. This repetitive MDA behavior is unacceptable.	scoping notification letter was sent to Mayor Carolyn Floyd in April 2003 and a copy of the Draft PEIS was provided to Mayor Floyd in September 2004.
Public Involvement	E0395-2	Communities most impacted by BMDS have been largely excluded from the environmental review process. For example, communities near Vandenberg AFB will disproportionately bear the burden of the proposed 515 launches over the next ten years. And, the PEIS has not sufficiently dealt with the effect of cumulative effects in Southern California, as many of the region's contractors are working on the weapon system. Simply, there needs to be additional hearings in potentially impacted areas of the nation.	It is not possible to hold public hearings at all locations where activities associated with implementing the BMDS may occur. MDA planned to hold its public hearings on the Draft PEIS in the same locations at which scoping meetings were held. The PEIS is a programmatic level analysis that considers implementation alternatives for an integrated BMDS and as such does not address specific sites or activities at these sites, but rather considers the program as a whole to allow tiering of subsequent site-specific analyses from the PEIS. In addition to the public hearings, the MDA developed a publicly accessible web site to provide information on the BMDS PEIS and request comments on the Draft PEIS. The MDA also established toll-free phone and fax lines, an e-mail address, and a U.S. postal service mailbox for submittal of comments and questions. Both the NOA of the Draft PEIS published in the FR and the BMDS PEIS web site provided instructions on submitting comments on the Draft PEIS. Comments received via any of the methods identified carry exactly the same weight as comments provided orally or in written format to MDA during a public hearing.
Public Involvement	PHO0025-4	Southern California is bearing a disproportionate impact of missile defense development and its effects on the environment. The midcourse interceptor is being tested	See previous response.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		and deployed at Vandenberg Air Force Base in Santa Barbara County. The Airborne Laser is being tested at Edwards Air Force Base in Los Angeles County. The space-based and Airborne Lasers are being developed by Northrop Grumman in the South Bay and San Juan Capistrano. Lockheed Martin, Boeing and Raytheon are deeply involved in developing the midcourse interceptors and other systems. At a minimum, there should be additional hearings near the areas most effected by missile defense developing.	
Public Involvement	PHO0029-1	But now I don't think so anymore because I'm noticing that there were only four locations at all where public testimony has been invited: Virginia, Sacramento, California, Hawaii and Alaska. That seems to me to be not nearly enough public input. That point has already been made. I would like to talk about Exhibit ES-3, which is part of the Executive Summary. If you want to go along with me, that exhibit shows the effected environment. This is about environment that we're talking about here today. I looked at that to see what the affected environment was. All of the environment that can be affected is divided into nine biomes, as well a broad ocean area and the atmosphere. I went through that and I saw the following. I saw that we're talking about the Arctic regions, North Atlantic Ocean, Pacific Ocean, Alaska, Canada and Greenland. Then some more Arctic regions and also Alaska, deciduous forest and Eastern and North Western U.S. and	See previous response.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		Europe, Chaparral. That is California Coast, Mediterranean from the Alps to the Sahara Desert, from the Atlantic Ocean to the Caspian Sea. This is a lot of area here. And these are areas that are labeled as "affected areas." Oh, the Grasslands. That is the whole prairie of the Midwest. The desert. Oh, the arid Southwest. New Mexico, Arizona, Utah and the Rocky Mountains, as well as the Alps, Pacific Equatorial Islands, which I don't know. Maybe that is why we're going to be in Hawaii. Northern -- you've got to turn the page. Northern Australia. And then how about the broad ocean area. That has no particular latitudinal range and that's the Pacific, Atlantic and Indian Ocean. And then the really big one, the atmosphere, which is the atmosphere which envelops the entire earth. That looks to me like a global environmental impact. And it seems to me only fair and some kind of rule that I think is codified in lots of different places that the people that are effected by legislation and -- and programs get to talk about it, get to respond. Well, that is going to be a lot more than the people in the U.S. Even if you say four hearings is enough in the U.S. -- this is a global environmental impact, this Star Wars Program. And, therefore, I'm not impressed with the hearing anymore. I think four is completely minimal.	
Public Involvement	PHO0047-1	Conduct one hearing in the Marshall Islands. After all, that's where the missile testing is taking place.	See previous response.
Public Involvement	PHO0047-2	How come I'm reading here that the request was given to have the hearing posed or made on Kauai, Maui, and the	See previous response.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		Marshall Islands, and it was refused? These are the most affected places that are going to be most impacted.	
Public Involvement	PHO0048-2	In addition, as everyone has stated, there should be more hearings held. The three on the continent and the one here are just not sufficient.	See previous response.
Public Involvement	PHO0050-2	Finally, I think if it's true that the Missile Defense Agency refused to have public meetings on Kauai where PMRF is and in the Marshall Islands, to me that's a very deep flaw.	See previous response.
Public Involvement	PHO0051-2	And it's amazing to me that you don't have a meeting scheduled in Kauai with almost half of an island impacted by the missile range facility there.	See previous response.
Public Involvement	PHO0058-1	In addition to my own opposition to the proposed ballistic defense system, I come here with words from people who were not offered the opportunity to testify this evening because there was no hearing on the island where they reside and where the impacts will take place.	See previous response.
Public Involvement	PHO0059-1	You really need to hold hearings on Kauai, other places also, but especially Kauai where the Pacific Missile Range Facility is located, who are really greatly impacted by this. And I, too, have friends on Kauai who didn't know about it and want the opportunity to testify.	See previous response.
Public Involvement	E0428-1	The following comments on the environmental and political effects caused by the proposed Ballistic Missile Defense System (MDS) are submitted a day late. I respectfully request that the deadline for submittal of comments be extended for cause. The cause is that there was very little notice to the general public, and only those versed as to the ADAMS or government notice agencies or methods were privy to the proposed invitation to comment.	Comments received through December 1, 2004 are considered in the Final PEIS. Comments received after December 1, 2004 have been included as part of the administrative record; however are not specifically addressed in this response appendix. In addition to the NOA, the MDA developed a publicly accessible web site to provide information on the BMDS PEIS and request comments on the Draft PEIS.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
Public Involvement	PHO0032-1	There's been no widespread publicity in California that we're aware of regarding this hearing today in Sacramento. Is this some sort of the stealth strategy to limit public input on such critical issues. The question is: Can the Draft PEIS be legitimate if there is not adequate notice of the document in the hearings on this matter?	Notification of the public hearings for the Draft BMDS PEIS was released in the NOA, which was published in the FR on September 17, 2004. In addition to the NOA, the MDA placed paid legal notices in the Sacramento Bee (October 13, 2004 and October 16, 2004) and the Lompoc Record (October 13, 2004, October 14, 2004, and October 15, 2004). The BMDS PEIS web site also listed the times and locations of the public hearings.
Public Involvement	PHW0005-1	I am here on behalf of Sacramento Area Peace Action and our 4,000 supporters, both to comment on the PEIS, and to register a complaint with the manner in which this hearing was scheduled. There has been no widespread publicity in California that we are aware of regarding this hearing today in Sacramento. Is this some sort of stealth strategy to limit public input on this crucial issue? We question if a Draft PEIS can be legitimate if there is not adequate notice of the document and the hearings on this matter.	See previous response.
Public Involvement	PHO0046-2	Again, I think that these processes have typically discouraged public participation. Whether that's by design or just by negligence, I think that it needs to be noted that there haven't been adequate efforts to reach out to the public, to provide accessible venues and opportunities for people to testify.	In addition to the public hearings, the MDA developed a publicly accessible web site to provide information on the BMDS PEIS and request comments on the Draft PEIS. The MDA also established toll-free phone and fax lines, an e-mail address, and a U.S. postal service mailbox for submittal of comments and questions. Both the NOA of the Draft PEIS published in the FR and the BMDS PEIS web site provided instructions on submitting comments on the Draft PEIS.
Public Involvement	PHO0046-3	As I said earlier, as Terri Kekoolani said earlier, Hawaiian translation is essential, the native Hawaiian language, Olelo Hawaii, is one of the official languages of Hawaii, and that should be honored in these proceedings so that when Hawaiian words are expressed, they are captured	Attendees at the public hearing were given the opportunity to provide testimony in both Hawaiian and Marshallese languages. A court reporter recorded the proceedings and the audiotapes were later translated by certified translators. Transcripts from the hearings,

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		correctly and not noted as inaudible or unintelligible, which is often the case.	including the translated oral Marshallese and Hawaiian testimony, can be found in Appendix B.
Public Involvement	PHO0046-4	Second, the question of native Hawaiian culture being an oral tradition, it's very important that you provide opportunities for people to give live testimony where they can look you in the eye and express what they are feeling. When you say that often written testimony or e-mail testimony is adequate, you effectively discriminate against a whole group of people who are actually one of the groups that are disadvantaged and should be considered as part of the environmental justice analysis of your Environmental Impact Statement.	Approximately 8,500 comment documents were received on the Draft BMDS PEIS. Comments received via any of the methods identified carry exactly the same weight as comments provided to MDA orally during a public hearing.
Public Involvement	PHO0048-1	First, notice and public hearing were inadequate. Although it's true that NEPA doesn't require them to hold a public hearing, it does require that the notice be on par with the extent of the program. And as they've clearly shown on their beautiful screen, this is supposed to have worldwide effect, yet we're only having, what, thirty of us here? I mean, this is affecting not only all of Hawaii, but all of the pacific and all of the entire world, and where was this hearing noticed in? Was it noticed on TV? Where did you guys hear about it? Word of mouth. I don't think notice was sufficient in this case, especially given the extent of this project.	The PEIS is a programmatic level NEPA analysis that considers implementation alternatives for an integrated BMDS and as such does not address specific sites or specific activities at those sites, but rather considers the program as a whole to allow tiering of subsequent site-specific analyses from the PEIS, as appropriate. The MDA planned to hold its public hearings on the Draft PEIS in the same locations at which scoping meetings were held. Notification of the public hearings for the Draft BMDS PEIS was released in theNOA, which was published in the FR on September 17, 2004. MDA also placed paid legal notices in various newspapers, which are outlined in Appendix B.
Public Involvement	PHO0051-1	First of all, the first comment I want to make has to do with the process. It is very deeply flawed. If what you are planning goes through, then obviously all islands will be impacted. Therefore, to properly inform our people here in Hawaii, you must have all people from all islands being	The PEIS is a programmatic level NEPA analysis that considers implementation alternatives for an integrated BMDS and as such does not address specific sites or specific activities at those sites, but rather considers the program as a whole to allow tiering of subsequent site-specific analyses from the PEIS, as appropriate.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		fully informed, which would include the Big Island, Maui, Molokai, Lanai, Ni'ihau, and Kauai.	
Public Involvement	PHO0051-3	Also, just alone coming on Oahu, you're having a meeting in a very small hotel, in a small room. The capacity of the room is sixty people.	Based on input provided during scoping, the public hearing location in Honolulu, Hawaii was determined based on availability of parking. The size of the conference room was adequate for the number of attendees.
Public Involvement	PHO0051-4	And so what it looks like is that you're kind of hiding, and that you are not looking for a way to actually get a lot of people to participate in this process.	Approximately 8,500 comment documents were received on the Draft BMDS PEIS during public hearings and via e-mail, mail, phone, and fax throughout the public comment period. The MDA has considered each comment in the development of the Final PEIS.
Public Involvement	PHO0058-2	Finally, I would like also to present the testimony of 1,330 people who signed petitions opposing the expansion of military in Hawaii. And these people need to be included in the process. They need to be notified of the Record of Decision.	MDA appreciates the participation of the petitioners in the BMDS PEIS public comment process. All public comments were taken into account during the preparation of the Final BMDS PEIS and have been included in the administrative record. MDA will place an advertisement in the Honolulu Adviser and the Honolulu Star Bulletin as a Notice of Availability of the Final BMDS PEIS. A copy of the Final PEIS will be posted on the MDA web site: http://www.mda.mil/mdalink/html/mdalink.html. The Record of Decision will be available in the Federal Register no less than 30 days after the publication of the final document.
Site Specific	E0319-3	5. A listing of the Test Sites where target missiles will be launched to be intercepted by the Airborne Laser	Site-specific environmental analyses have been prepared for past MDA activities and will continue to be prepared as appropriate. These future site-specific analyses will tier from this PEIS. Several NEPA documents have been prepared to address proposed activities at the PMRF and consider potential impacts to cultural

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
			resources. These analyses include but are not limited to the EIS for the Strategic Target System, the Kauai Test Facility EA, the PMRF Enhanced Capability EIS, and the North Pacific Targets Program EA. Analyses for site-specific MDA actions taking place OCONUS would consider environmental impacts per EO 12114, Environmental Effects Abroad of Major Federal Actions, as well as DoD established Final Governing Standards for environmental compliance requirements for military activities overseas, which take into account the DoD's Overseas Baseline Guidance Document and applicable host-national or international environmental standards. Testing is carried out at appropriate test facilities, ranges and other government installations as determined after considering and evaluating environmental, safety, logistical, cost, schedule, and other technical feasibility issues as well as the test objectives. NEPA analyses of environmental impacts of specific subsequent test activities at sites would be tiered from the PEIS, as appropriate.
Site Specific	E0347-2	The Missile Defense Agency's Programmatic Environmental Impact Statement must acknowledge and include Environmental Impact Assessments for each and every US Missile Defence Base proposed to be sited on land in nations with British or British Commonwealth status, and also in other independent sovereign nations (e.g. Denmark's sovereignty over Thule).	See previous response.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
Site Specific	E0387-1	We are disappointed however that the PEIS will only be undertaken for component bases in the United States and not for overseas bases integral to the system, such as Fylingdales. From our experience of talking to the residents close to the Fylingdales base, we are aware of a constant concern about its role in the "Son of Star Wars" program and a desire for more information and accountability from the developers of the system. The local population in the vicinity of this base has both environmental and security concerns regarding the base's role in Missile Defence that ought to be addressed in such a study. The same also applies for Menwith Hill - considered highly likely to play a key role as the Ground Based Relay Station for the Space Based Infra Red System - and these concerns will grow if the United States is granted permission to use the base for Missile Defence by the UK Government.	See previous response.
Site Specific	E0387-2	Furthermore, there exists a large, informed section of society, not necessarily within the vicinity of these particular bases, that is also legitimately concerned as to the potential impact on UK and global security as a result of the Missile Defence system. Despite the UK's involvement in the system this group too will not be represented by this study.	See previous response.
Site Specific	E0387-3	Despite the fact that the PEIS has currently declared that it will only consider component bases of Missile Defence based in the US, we will refer to the Yorkshire bases both in the hope that the PEIS will recognise the importance of expanding its remit to cover Missile Defence bases beyond the USA mainland, and partly because the	See previous response.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		concerns that surround these bases can be equally applied to their US-based equivalents.	
Site Specific	F0004-1	1 Take this whole program out to the Aleutian Islands! That's were all this experimental D.O.D. stuff should have been put all along. This is all testing. The Kodiak people + flora + fauna should not be used this way. Take it West to Adak + Shemya where the D.O.D. has been set-up doing "there thing" since prior to WWII! Just by the Adak base back from the Native Corp. (It should have never been sold to them in the first place!) You have all your infrastructure already there too. You can do lots of experiments out there with lil effects on US citizens if done correctly.	See previous response.
Site Specific	F0004-6	5 You do not need to let the AADC gobble-up any-more land to use for this program. The additional 14,000 Acres is our only area on the Kodiak Road System we (the citizens) have that is open for public use. All the other land is private (Native Corps and 3/4 of the Island is in the Kodiak Island National Wildlife Refuge. Please DO NOT take control of these lands. No more land to USE. (the 3,800 Acres you use now is enough. No more ok.	See previous response.
Site Specific	PHO0051-9	That is already taking place right now on Kauai. You folks have missile launching pads over there on top of an ancient burial ground.	See previous response.
Site Specific	PHO0051-10	And also there are now people being denied access to beach fronts that have traditionally always been accessible by our people.	See previous response.
Site Specific	E0319-5	7. If missiles are being proposed for launch from Fort Greeley, Alaska	MDA conducted a preliminary study looking at the technical feasibility of test launching GBIs from Fort Greely in April 2004, but has not yet decided on a proposed test action, thus a NEPA process has not yet

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
			begun. Specifically, MDA performed a feasibility study of possible flight trajectories from Fort Greely considering the operationally realistic engagements, target launch sites, and safety. MDA then conducted a range safety assessment of the most feasible GBI trajectories. This study identified three potential flight corridors that if subjected to a more refined and rigorous flight safety analysis could pass range safety standards. Results of this additional study could be used as inputs to MDA's subsequent environmental studies. MDA also is building a Geographic Information System (GIS) to facilitate our analysis by mapping Alaska region data. This GIS analysis will assist MDA planners in developing potential flight test that would be subjected to safety and environmental analysis if MDA considers continuing planning towards a decision for test launches from Fort Greely.
Site Specific	E0319-7	NOTE: Regarding Fort Greeley, Alaska- is the MDA proposing to launch future 'interceptors' in a 'north trajectory' (or south trajectory), over Alaska native villages from that location? If so, the PEIS should list all safety drop-zones for falling booster stages and proposed trajectory launches, along with what safety steps will be taken to protect natives in their villages. Also include potential cumulative environmental damage to the tundra from falling boosters.	See previous response.
Site Specific	E0319-6	8. Information on proposed BMDS launches from Poker Flats Rocket Range, Alaska	At the time this PEIS went to print, there were no planned BMDS launches from Poker Flats Rocket Range, Alaska in the near future. However, should BMDS activities be required at Poker Flats, site-specific

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
			environmental analyses would be prepared. These future site-specific analyses would tier from this PEIS.
Site Specific	E0319-9	There has not been an environmental assessment since 2001 (that the public is aware of) regarding the reliability of the STARS missile to justify the continuation of this launch vehicle. The November 2001 STARS launch from the Kodiak Launch Complex resulted in failure (the missile 'exploded' 7 miles off Kodiak's shores after launch and the MDA attempted to cover up the accident). No public reports were released on this launch failure. The STARS missile has not been improved since the early 1990's launch failures from Kwajalein Atoll. This program should be discontinued due to its unreliability, safety hazards, and pollution to air and water.	Testing is carried out at appropriate test facilities, ranges and other government installations as determined after considering and evaluating environmental, safety, logistical, cost, schedule, and other technical feasibility issues as well as the test objectives. This PEIS provides a roadmap for site-specific analyses of the environmental impacts of BMDS activities. There are inherent risks with any missile testing activity; however, protection of life and property, on and off range, is the prime concern of Range/Mission Safety personnel. The RCC Common Risk Criteria for National Test Ranges (RCC 321-02) sets the requirements for minimally acceptable risk criteria to occupational and non-occupational personnel, test facilities and nonmilitary assets during range testing operations. Under RCC 321-02, individuals of the general public shall not be exposed to a probability of fatality greater than 1 in 10 million for any single mission and 1 in 1 million on an annual basis. Range Safety personnel also apply launch window criteria that consider various weather and climatic conditions, as appropriate.
Site Specific	E0319-12	The Alaska Aerospace Development Corporation (a.k.a. Missile Defense Agency) has requested jurisdiction over an additional 14,000 acres of Narrow Cape 'public' land on Kodiak Island, Alaska, over and above the 3,800 acres it already has jurisdiction over. The PEIS should include what type of BMDS testing/activity is being proposed for the Kodiak Launch Complex that would require almost 18,000 acres of public land. Since the request was made	As described in the previous response, protection of life and property, on and off range, is the prime concern of Range/Mission Safety personnel. For this reason, temporary closures of public lands and roads during launch activities may be necessary for safety and security reasons. The Alaska Department of Natural Resources Division of Mining, Land and Water authorized periodic, temporary closures of Narrow Cape in April 2005 after a

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		after the release of the July 2003 Ground-Based Midcourse Defense (GMD)-Extended Test Range FEIS, the reason for the request should have been included in the BMDS Draft PEIS.	thorough public review. The Alaska Aerospace Development Corporation made the request for this ability to close public lands as an additional safety buffer for its own operational reasons; MDA did not make this request. However, if similar issues arise in the future as a result of MDA activities at KLC they will be considered in site-specific documentation tiered as appropriate from this PEIS. The MDA understands the sensitivity of closing public lands even for a short period and every effort would be made to ensure that such closures do not create undue burden on local residents.
Site Specific	E0319-15	Kodiak Launch Complex and Kodiak Island issues that should have been discussed in detail in the BMDS Draft PEIS are: 1. Island-wide areas that will be evacuated for BMDS activity 2. Health and Safety procedures for exposure to launch debris-especially for potentially affected populated native villages such as Old Harbor and Akhiok 3. Doing a site-specific operating document (referred to in Volume 2, page H-13) 4. The potential electromagnetic explosive devices, ionizing and non-ionizing radiation hazards 5. Hazards and trajectories of interceptors 6. Special Use Airspace and Domestic Warning Areas	As stated throughout the PEIS, this document is intended to serve as a tiering document from which future site-specific NEPA analyses will be tiered. These analyses can consider the potential impacts of specific safety plans and trajectories of interceptors for individual tests. Section 4.1.1.2 of this document provides an overview of Health and Safety Procedures, special use airspace and warning areas, as well as potential impacts of the use of missile launches.
Site Specific	E0319-16	'Generally, sites where activities for the proposed BMDS activities may occur are located far from towns and population centers and are surrounded by open space' (PEIS Volume 2, page H-14). This does not apply to the Kodiak Launch Complex. The test site is located only a few miles from a populated and State of Alaska	Existing site-specific environmental analyses for activities at Kodiak Launch Complex (KLC) include the GMD ETR EIS, the EA for USAF Atmospheric Interceptor Technology Program, the Final EA for USAF Quick Reaction Launch Vehicle Program, the North Pacific Targets Program EA and the FAA EA for the

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		recreational area. Cabins, homes, bed and breakfast accommodations are located near the Pasagshak River, which is highly frequented by fishermen and tourist during summer months, and hunters and recreational users during the winter months. Cabins and homes are in year-around use in the winter unless the roads are impassable due to snow coverage. However, this is not expected to be a problem since the road to the launch site has to be accessible to workers (especially in preparation for an upcoming launch). The PEIS needs to discuss proposed BMDS activity on Kodiak Island in detail.	KLC, Kodiak Island. Further, the PEIS is intended to provide a programmatic analysis of the potential impacts associated with the development, testing, deployment, and decommissioning of the BMDS. The PEIS is not a site or component specific environmental analysis, and therefore does not provide specific information about particular components or their operation at various facilities. As specific test requirements become known NEPA analyses will be prepared, appropriately tiered from this PEIS.
Site Specific	E0319-11	The PEIS should include all proposed laser test sites including the BOA, and, what experiments will take place at each site, and the total amount of acreage needed as a safety zone. For example, will the Airborne Laser 'test fire' at targets or interceptors launched from Vandenberg AFB, Kwajalein, Kodiak Island, Fort Greeley, or Poker Flats Rocket Range, Alaska?	The MDA process for selecting BMDS test locations is based upon criteria developed by the MDA system engineering team (e.g., Systems Engineering and Force Structure Integration and Deployment, and the Elements) to include engagement sequence groups, system test objectives, and overall system design. The team develops a System Event Test Program based on simulation models, pre-test analysis, post-test evaluation (verification of objectives) and produces a requirements matrix for each Test Bed Block. The test requirements are tailored to the availability and capability of test assets and the configuration constraints imposed by the test ranges. From the Test Bed Block Matrix, test objectives and range requirements are derived for each BMDS test event which undergoes a formal coordination process. SE delivers the final test objectives and range requirements to the Combined Test Force (CTF) for execution.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
			The CTF, through the PRST, assists the program element/mission test director in further defining the required range support. The PRST consolidates the personnel resources, range assets and instrumentation and capabilities necessary to efficiently conduct end-to-end BMDS-level flight testing in the Pacific. The PRST then recommends the test range(s) best suited to achieve the test objectives.
Site Specific	E0347-1	Crucial to the US Missile Defence programme is the stationing of 'forward surveillance' facilities located outside the continental USA at US Bases on land it is permitted to use by host nations. The political structure of such nations may be very different from the Federal Government (e.g. Britain is a Monarchy: q.v. 'Crown Defence Land'). The legislation regulating environmental controls in other countries may be very different, possibly more stringent, than that which obtains within the USA. It is incumbent on the Missile Defense Agency to apprise itself of, and publish an undertaking to comply with, mandatory statutory requirements wherever on the Earth it proposes to site Missile Defence facilities.	The PEIS analyzes the programmatic development, testing, deployment, and planning for decommissioning activities for an integrated BMDS. Site-specific actions would be analyzed in subsequent NEPA analyses that would tier from this document, as appropriate. Analyses for site-specific MDA actions taking place OCONUS would consider environmental impacts per EO 12114, Environmental Effects Abroad of Major Federal Actions, as well as DoD established Final Governing Standards for environmental compliance requirements for military activities overseas, which take into account the DoD's Overseas Baseline Guidance Document and applicable host-national or international environmental standards.
Site Specific	E0427-29, E0439-29	26) Which government and university institutions in the State of California will be conducting research to support the BMDS research and development and, if so, please describe their roles, responsibilities and the specific projects they will be involved in? Specifically, will Lawrence Livermore National Laboratory, Lawrence Berkeley National Laboratory, Sandia National Laboratory - Livermore, or the University of California at Berkeley, Davis or Los Angeles be conducting research or development on the BMD for the MDA or DoD and, if so,	The PEIS analyzes the programmatic development, testing, deployment, and planning for decommissioning activities for an integrated BMDS. Specific facilities that would be used to carry out subsequent activities comprising the life cycle phase testing would be analyzed in site-specific documents. These subsequent NEPA analyses could tier from this PEIS as appropriate.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		what specifically will each that is involved be doing? This is important for people in these areas to know in order to understand, consider and evaluate the possible environmental, health, and safety impacts on their communities.	
Site Specific	F0004-2	1 The planned rocket trajectories that go over Kodiak Island + skirt very close to the East Side are just totally unacceptable! We have to many Native Villages + Bush people who live there year round. NOT to mention all the wildlife (Bears! Rare Kodiak Brown Bears!) that live there too. It is just to damn dangerous to launch over the Island. Period! That can NOT proceed	As stated in Section 4.1.1.2, Health and Safety, launch activities would be conducted when trajectory modeling verifies that launch-related debris would be contained within predetermined areas, all of which would be located away from populated areas.
Tiered Analyses	E0429-11	Waiting for site-specific analysis in the indefinite future condemns project sites to acid precipitation. There is no hint of how such an environmental impact might be mitigated. The proper analysis, at this stage, is to consider how the missile defense program might develop and test alternate launch technologies that are not so environmentally destructive. That is, the best solution is not likely be site-specific, so the PEIS itself should evaluate this impact.	The BMDS PEIS considers the use of a wide variety of propellants including three types of boosters, pre-fueled liquid propellant, non-pre-fueled liquid propellant, and solid propellant boosters. The environmental impacts of each of these three types of boosters have been considered and are presented in Section 4.1.1.2 of the PEIS. However, it is appropriate to analyze the potential impacts of launching specific test vehicles from particular sites in subsequent tiered site-specific NEPA documentation, and the MDA will consider the environmental impacts of conducting test launches in such documentation, as appropriate.
Tiered Analyses	PHW0004-11	Waiting for site-specific analysis in the indefinite future condemns project sites to acid precipitation. There is no hint of how such an environmental impact might be mitigated. The proper analysis, at this stage, is to consider how the missile defense program might develop and test alternate launch technologies that are not so environmentally destructive. 		not likely be site-specific, so the PEIS itself should evaluate this impact.	
Tiered Analyses	E0429-21, PHW0004-21	Overall, the PEIS puts off consideration of the challenge of waste decommissioning, stating, "The environmental impacts associated with decommissioning of specific components would be more appropriately addressed in subsequent tiered environmental analysis..." (ES-20) This is unacceptable. It can only lead to "end-of-pipe" solutions, even though the Defense Department's own environmental managers and specialists agree that environmental protection should be integrated into acquisition and even research and development. The 2001 Munitions Action Plan, for example, states: The current emphasis in acquisition of munitions of all types (air delivered, ground launched, and sea launched) is on improving accuracy, reliability and increasing distances between firing or launch points and targets (i.e., so-called standoff ranges). At the same time, the public and regulatory bodies are raising concerns about safety and the environmental effects of munitions. The DoD is also becoming more aware of the cleanup and environmental compliance costs associated with training, testing, demilitarization, and unexploded ordnance (UXO) responses. These developments have highlighted the need for DoD to address environmental and safety concerns, and costs, throughout the munitions life cycle. This cycle starts from the technology development and design phase to the end-	Section 4.0 of the PEIS provides a roadmap for considering impacts of decommissioning for each component. However, as stated in the BMDS PEIS, the environmental impacts of demilitarization and disposal are more appropriately considered in subsequent tiered analyses. The MDA is actively engaged in considering and evaluating ways to minimize environmental impacts in the design, test, and development of the BMDS. Specifically Appendix M of the PEIS considers the demilitarization, reclamation, declassification and disposal of solid rocket propellant.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		state of use, UXO and munitions constituents cleanup on ranges, or demilitarization. Addressing these concerns early in the life cycle (during requirements definition and acquisition) has the potential to significantly reduce costs and avoid problems later. [Footnote 16: Munitions Action Plan: Maintaining Readiness through Environmental Stewardship and Enhancement of Explosives Safety in the Life Cycle Management of Munitions, U.S. Department of Defense Operational and Environmental Executive Steering Committee for Munitions (OEESCM), November 2001, page 16.] That is, if the review of the potential environmental impacts of a system such as the BMDS finds the potential for significant negative environmental impacts, then those designing the system, selecting programmatic alternatives, and managing its testing and deployment should continuously evaluate ways to minimize those impacts, from the beginning.	
Tiered Analyses	F0005-13	II. The draft PEIS fails to analyze what would be required to develop a space-based test bed; dismissing the suggestion as "too speculative." But that is precisely what the PEIS is supposed to - to examine the environmental effects of the proposed action. Accordingly, the draft PEIS is flawed for not looking at the effect of space-based interceptors in lieu of terrestrial-based ones - it simply suggests that future studies may be required. This dismissive attitude toward NEPA would not survive judicial scrutiny.	Alternative 2 includes the use of weapons from land-, sea-, air-, and space-based platforms. The use of space-based weapons is analyzed in Section 4.2; specifically, Section 4.2.1 analyzes the use of interceptors, including the impacts from launch/flight and debris, from a space-based platform. However, as stated in the PEIS the analysis of a space-based test bed is not mature enough for NEPA analysis at this time.
Tiered Analyses	F0005-19	(5) The PEIS should review the testing, of future laser weapons systems and specify testing plans for other high-	Appendix F of this PEIS describes various advanced systems that are currently under review by the MDA.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		power laser weapons and other energy-directed weapons. It does not.	The PEIS is intended to provide a programmatic analysis of proposed BMDS activities. The PEIS considers the potential impacts of the BMDS as currently envisioned. Specific testing programs of undeveloped directed energy weapons are not yet known and cannot be analyzed in environmental analyses. As the technology for these programs matures and the MDA develops testing scheduled for such advanced directed energy weapon systems, appropriate environmental analyses will be conducted.
Tiered Analyses	M0268-1	The MDA knows at present from where ground based interceptors will be launched, and site specific studies should be absolutely required in the PEIS.	The MDA analyzed the impacts of constructing and operation of GBI sites at Vandenberg AFB in the GMD Vandenberg Air Force Base IDOC EA and at Fort Greely in the GMD Validation of Operational Concept (VOC) EA. The PEIS is a programmatic analysis and is intended to serve as a tiering document for future site-specific analyses. Future actions involving the construction and operation of interceptors from specific locations would be addressed in subsequent site-specific analyses tiered from the PEIS as appropriate.
Tiered Analyses	M7903-1	My perspective is that of a long time resident of Interior Alaska familiar with the Fort Greely area where one of the missile sites is currently under development. Unfortunately, the selection of this site was not adequately evaluated in relation to the environmental sensitivity of this area. Inadequate consideration was given to the fact that the site sits on top of the flowage of a unique aquifer that flows through the glacial outwash gravels from the Alaska Range mountains to the south, under Fort Greely, and emerges as springs that feed the Delta Clearwater River and lake system. Because of the upwelling water of	The MDA analyzed the activities at Fort Greely in the GMD VOC EA. The PEIS is a programmatic level analysis that addresses the implementation alternatives for an integrated BMDS and as such does not consider specific sites or activities at specific sites. Any future site-specific activities occurring at Fort Greely or other sites in Alaska would consider potential environmental impacts from spills of contaminants or fuels in subsequent tiered analyses, as appropriate.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
		the Delta Clearwater system it is one of the most productive salmon spawning complex and young salmon rearing area on the entire Yukon-Tanana River system. Any significant leakage or spill of contaminants, inclusive of fuels, and radioactivity contaminated water or other materials would have the potential for devastation to both the commercial and subsistence fisheries of the Yukon River and [sic] Bering Sea through direct affects on the fish, as well as the thousands of people dependent upon the fish for their nutrition, health, and economy. Additional studies need to be done to assess this potential threat to the Alaska environment and its people and to assess the possible need for mitigative planning, spill contingency development, and testing for background leakage levels from the post World War II use of Fort Greely as a biological and chemical warfare testing site.	
Tiered Analyses	PHO0038-3	I'm really concerned about the aborted launch that happened at Kodiak, I believe it was two years ago November and Kodiak itself is a significant enough population center to be concerned about it, but if we start launching missiles from Fort Greeley, which is near Fairbanks, near Delta Junction, that have to be aborted, there's significant population centers there, not to mention the TransAlaska Pipeline.	The PEIS is a programmatic level analysis that addresses the implementation alternatives for an integrated BMDS and as such does not consider specific sites or activities at specific sites, such as the KLC or Fort Greely. Prior activities have been analyzed in NEPA analyses as cited in the PEIS. Future activities would be analyzed in subsequent tiered analyses. In addition, as stated in Section 4.1.1.2, launch hazard areas would be determined before a test launch is conducted from a site. Potential impact zones for launch debris would be delineated based on detailed launch planning and trajectory modeling. Flights would be conducted when trajectory modeling verifies that launch-related debris would be contained within predetermined areas, all of which would be located away from populated areas.

Exhibit K-5. Response to Comments – Proposed Action and Alternatives

Issue Topic	Comment Number	Excerpt Text	Response
Tiered Analyses	PHO0038-4	It's unclear from the PEIS, and I'm looking at Section 2.242, whether or not the Kodiak Launch Complex is going to be a launch test and defensive operational asset or if it's going to launch things into orbit, or if it's just a test center. So it's confusing for the folks on Kodiak and for us here in Alaska what is actually going to happen out on the island. It talks about a safety zone that would be established around the laser during activation. This is also in the PEIS, Pages 250 to 254. There's a lot of small plane traffic and a lot of small boat traffic around Kodiak and other places in Alaska. It has us concerned about the laser and its effects on our economy and on the human resources, or humans, I should say, of Alaska.	The PEIS is a programmatic environmental analysis. The PEIS does not consider the testing or operation of specific components at specific locations. The KLC is currently licensed by the FAA to conduct up to nine launches of vehicles weighing less than 500,000 pounds total with SRM primary stages with less than 369,000 pounds of Class I, Division 3 explosives. If additional launches in support if MDA testing were proposed, these activities could be analyzed in subsequent analysis tiered from the PEIS. In addition, the impacts to plane and boat traffic in Kodiak from the establishment of a safety zone for potential future laser activities would be analyzed in additional NEPA documentation, as necessary.
Tiered Analyses	PHW0002-3	This draft PEIS also does not look at what would be required to develop a space-based test bed, dismissing the concept as being "too speculative to be analyzed in this PEIS." (p. 2-29) It does not say when such a concept would be analyzed. Finally, this document admits, "If Alternative 2 were selected, additional environmental analysis could be needed as the technologies intended to be used became more defined and robust." (p. 4-116) But again, that is what this document is supposed to do: examine the environmental effects of the proposed action. By sweeping it under the nebulous responsibility of future studies, it relieves the MDA of liability of negative consequences stemming from SBIs.	The PEIS analyzes the use of space-based weapons as discussed in Section 4.2. Specially, Section 4.2.1 analyzes the use of interceptors, including the impacts from launch/flight and debris, from a space-based platform. However, as stated in the PEIS the analysis of a space-based test bed is not mature enough for NEPA analysis at this time.

K.5 Federal Agency Comment Documents

This section addresses comment documents submitted by Federal Agencies. All comment documents submitted by Federal Agencies are reproduced in Section K.5.1. Responses to specific comments submitted by Federal Agencies are provided in Section K.5.2. Section K.5.2 includes the comment document number and sequential number of the comment, the resource area addressed by the comment, the text of the comment, and MDA's response. Where appropriate, revisions to the Final BMDS PEIS were made in response to these comments.

K.5.1 Reproductions of Federal Agency Comment Documents

Subject: NOAA Comments on Draft BMDS PEIS

Ramona.Schreiber.vcf (441 B)

Dear Project Manager:

The National Oceanic and Atmospheric Administration is composing its comments on the Draft BMDS PEIS. As a thorough review under the Magnuson Stevens Act Essential Fish Habitat requirements, Endangered Species Act, and Marine Mammal Protection Act is involved, our comments may be delayed. We anticipate providing them within the week. Please accept them in that format as we are a Federal partner of yours.

Thank you in advance,
Ramona Schreiber

Missile Defense Agency
Ballistic Missile Defense System PEIS
c/o ICF Consulting
9300 Lee Highway
Fairfax, VA 22031

Dear Mr. Lehner:

In accordance with our responsibilities under Section 309 of the Clean Air Act and the National Environmental Policy Act (NEPA), the Environmental Protection Agency (EPA) has reviewed the Missile Defense Agency's (MDA) Ballistic Missile Defense System (BMDS) Draft Programmatic Environmental Impact Statement (DPEIS) (CEQ # 040438).

The DPEIS identifies, evaluates and documents, at the programmatic level, the potential environmental impacts of activities associated with the development, testing, deployment, and planning for the eventual decommissioning of the BMDS. It considers the current technology components, support assets, and programs that make up the proposed BMDS as well as the development and application of new technologies.

EPA commends the efforts that MDA has commenced in producing such a comprehensive and well organized document. We also appreciate your efforts in utilizing the extensive environmental analysis that is available for many of the existing components of the proposed BMDS. Based on our review of the DPEIS, we have rated the document as LO - Lack of Objections (see attached "Summary of EPA Rating System"). Although EPA has no objections to the proposed action, there are a few issues that should be clarified.

DC_F0003

1) General Comments:

a. To assess the impacts of implementing the proposed BMDS, the DPEIS characterized the existing condition of the affected environment in the locations where various BMDS implementation activities are proposed to occur. MDA has determined that activities associated with the proposed BMDS might occur in locations around the world. Therefore, the affected environment has been considered in terms of global biomes, broad ocean areas, and the atmosphere. This has resulted in the DPEIS being very conceptual and general in nature. EPA understands that once potential BMDS locations are determined, more detailed site-specific documents will be prepared. Through the discussions on the "block approach" or the "block development process", the DPEIS has given clear indications of when follow-on NEPA analysis will occur. We agree with this approach. However, while the documents give representative examples of past, current, or proposed locations where proposed activities may occur within each biome, EPA recommends that the EIS discuss the criteria that MDA will use in making future decisions for site-specific locations.

b. The resource areas considered in this analysis are those resources that MDA believes can potentially be affected by implementing the proposed BMDS. EPA agrees that some resource areas are site-specific or local in nature and, therefore, cannot be effectively analyzed in this type of programmatic document and that the potential impacts on these resources are more appropriately discussed in subsequent site-specific documentation tiered from this PEIS. However, EPA recommends that the final document discuss the existence of multiple species habitat conservation planning efforts that are proximate to DoD lands and the potential impacts of debris on marine and aquatic ecosystems.

c. As suggested by CEQ regulations, MDA has taken advantage of the extensive environmental analyses that already exist for many of the existing components of the proposed BMDS by incorporating these materials into the DPEIS by reference. However, some of these documents are greater than 10 years old. The PEIS should confirm the validity of the information in these documents.

2) Perchlorate Comment: Because there have been differing interpretations of the science associated with the impact on human health from low level exposure to perchlorate and in the interest of resolving scientific questions, EPA, the Department of Defense, the Department of Energy, and the National Aeronautics and Space Administration - members of a broader Interagency Working Group on Perchlorate led by the Office of Science and Technology Policy - have referred scientific issues and EPA's 2002 Draft Health Assessment on Perchlorate to the National Academy of Science (NAS) for review. NAS is currently conducting a study to determine the best science and model to use for determining the health impacts and standards for perchlorate. A report on this study is expected to be completed by the end of 2004. EPA recommends that the results of the report be incorporated into the FPEIS.

DC_F0003

We appreciate the opportunity to review this DPEIS. We also look forward to reviewing the FPEIS related to this project. The staff contact for the review is Marthea Rountree and she can be reached at (202) 564-7141.

Sincerely,

for

Anne Norton Miller
Director
Office of Federal Activities

Enclosure: Summary of Rating Definitions

DC_F0003

SUMMARY OF EPA RATING SYSTEM

Rating the Environmental Impact of the Action

- **LO (Lack of Objections)** The review has not identified any potential environmental impacts requiring substantive changes to the preferred alternative. The review may have disclosed opportunities for application of mitigation measures that could be accomplished with no more than minor changes to the proposed action.
- **EC (Environmental Concerns)** The review has identified environmental impacts that should be avoided in order to fully protect the environment. Corrective measures may require changes to the preferred alternative or application of mitigation measures that can reduce the environmental impact.
- **EO (Environmental Objections)** The review has identified significant environmental impacts that should be avoided in order to adequately protect the environment. Corrective measures may require substantial changes to the preferred alternative or consideration of some other project alternative (including the no action alternative or a new alternative). The basis for environmental objections can include situations:
    1. *Where an action might violate or be inconsistent with achievement or maintenance of a national environmental standard;*
    2. *Where the Federal agency violates its own substantive environmental requirements that relate to EPA's areas of jurisdiction or expertise;*
    3. *Where there is a violation of an EPA policy declaration;*
    4. *Where there are no applicable standards or where applicable standards will not be violated but there is potential for significant environmental degradation that could be corrected by project modification or other feasible alternatives; or*
    5. *Where proceeding with the proposed action would set a precedent for future actions that collectively could result in significant environmental impacts.*
- **EU (Environmentally Unsatisfactory)** The review has identified adverse environmental impacts that are of sufficient magnitude that EPA believes the proposed action must not proceed as proposed. The basis for an environmentally unsatisfactory determination consists of identification of environmentally objectionable impacts as defined above and one or more of the following conditions:
    1. *The potential violation of or inconsistency with a national environmental standard is substantive and/or will occur on a long-term basis;*
    2. *There are no applicable standards but the severity, duration, or geographical scope of the impacts associated with the proposed action warrant special attention; or*
    3. *The potential environmental impacts resulting from the proposed action are of national importance because of the threat to national environmental resources or to environmental policies.*

Adequacy of the Impact Statement

- **Category 1 (Adequate)** The draft EIS adequately sets forth the environmental impact(s) of the preferred alternative and those of the alternatives reasonably available to the project or action. No further analysis or data collection is necessary, but the reviewer may suggest the addition of clarifying language or information.
- **Category 2 (Insufficient Information)** The draft EIS does not contain sufficient information to fully assess environmental impacts that should be avoided in order to fully protect the environment, or the reviewer has identified new reasonably available alternatives that are within the spectrum of alternatives analyzed in the draft EIS, which could reduce the environmental impacts of the proposal. The identified additional information, data, analyses, or discussion should be included in the final EIS.
- **Category 3 (Inadequate)** The draft EIS does not adequately assess the potentially significant environmental impacts of the proposal, or the reviewer has identified new, reasonably available, alternatives, that are outside of the spectrum of alternatives analyzed in the draft EIS, which should be analyzed in order to reduce the potentially significant environmental impacts. The identified additional information, data, analyses, or discussions are of such a magnitude that they should have full public review at a draft stage. This rating indicates EPA's belief that the draft EIS does not meet the purposes of NEPA and/or the Section 309 review, and thus should be formally revised and made available for public comment in a supplemental or revised draft EIS.

Dear Project Leader:

Thank you for the opportunity to review the Missile Defense Agency Ballistic Missile Defense System Programmatic Environmental Impact Statement. On behalf of the National Oceanic and Atmospheric Administration (NOAA), provided here are comments developed by NOAA's National Marine Fisheries Service (NOAA Fisheries). NOAA's responsibilities include conservation of resources under the Magnuson-Stevens Act Essential Fish Habitat provisions, Endangered Species Act, and Marine Mammal Conservation Act.

Should you have questions and when you are ready to consult further with NOAA regarding requirements under the above statutes, please contact the NOAA Fisheries Southwest Regional Office at 562-980-4000.

Sincerely,

Ramona Schreiber
For Susan A. Kennedy
Acting NEPA Coordinator

Attachment

NOAA Fisheries Southwest Region's comments for inclusion in a NOAA response for the Missile Defense Agency's proposed Ballistic Missile Defense System

The Southwest Region, National Marine Fisheries Service (SWR) has reviewed the September 1, 2004, draft Programmatic Environmental Impact Statement (draft PEIS) for the Missile Defense Agency's proposed Ballistic Missile Defense System (BMDS). The purpose of the proposed action is for the Missile Defense Agency to incrementally develop and field a BMDS that layers defenses to intercept ballistic missiles of all ranges in all phases of flight. The BMDS is proposed to be a layered system of defensive weapons that have the potential to impact particular trust resources of NOAA during activities associated with the development, testing, deployment, and planning for decommissioning of the BMDS. This memo letter the SWR's comments on the proposed action under purview of the Essential Fish Habitat (EFH) provisions in the Magnuson-Stevens Fishery Conservation and Management Act (16 U.S. C. 1855, *et. seq.*), and protected resource provisions in the Marine Mammal Protection Act (16 U.S.C. 1361 *et. seq.*), and the Endangered Species Act (16 U.S.C. 1531 *et. seq.*).

Essential Fish Habitat Conservation Recommendations
Pursuant to 16 U.S.C. § 1855(b)(2) of the Magnuson-Stevens Act, Federal agencies are required to consult with the Secretary of Commerce (delegated to NOAA Fisheries) with respect to "any action authorized, funded, or undertaken, or proposed to be authorized, funded, or undertaken, by such agency that may adversely affect any essential fish habitat identified under this Act." In addition, the Magnuson-Stevens Act also requires the Secretary of Commerce recommend to the federal action agency particular measures that can be taken by such agency to conserve fish habitat (16 U.S.C. § 1855(b)(4)(A).

This consultation involves the EFH of anadromous and marine species managed by the Pacific Regional Fishery Management Councils within the Exclusive Economic Zone of the United States for the Pacific Salmon Fishery Management Plan (FMP), the Coastal Pelagic Species FMP, the Pacific Groundfish FMP, and the Highly Migratory Species FMP. These species utilize various habitats that include riverine, estuarine, and marine systems and these habitats may be adversely affected by some of the activities associated with the development, testing, deployment and planning for decommissioning of the BMDS. Primarily, the agency is concerned about potential release of hazardous materials (e.g., chemicals, propellants, propellant by-products, launch emissions) that potentially could be released directly and indirectly to the habitat types listed above during various phases of the BMDS. In order to minimize these potential impacts, the SWR advises the following:

1. NOAA Fisheries recommends that the Missile Defense Agency be responsible for handling and disposing of all hazardous materials or hazardous wastes in all phases of the proposed action in accordance with applicable Federal, state, and local laws, utilizing best management practices at all life cycle activities of the proposed action and through appropriate project planning and design measures including appropriate spill prevention, control and contingency plans (e.g., Oil Discharge Prevention and Contingency Plan, Storm Water Pollution Prevention Plan) for each site.

Endangered Species Act

Based on the information provided in the draft PEIS, NOAA Fisheries recommends that the Missile Defense Agency consult with the appropriate NOAA Fisheries Regional Office to determine if listed species under the Endangered Species Act (ESA) of 1973 as amended (16.U.S.C. 1531 *et. seq.*) may be affected by the proposed project. If it is determined that this project may affect a listed or proposed species, the Missile Defense Agency should request initiation of consultation with NOAA Fisheries pursuant to section 7 of the ESA.

Marine Mammal Protection Act

Whales, dolphins, seals, and sea lions are protected under the Marine Mammal Protection Act (MMPA). Under the MMPA, "take" of a small number of marine mammals is permitted by NOAA Fisheries under an Incidental Harassment Authorization (IHA) when the specified activity is incidental, but not intentional. "Take" is defined as harassing, hunting, capturing, or killing, or attempting to harass, hunt, capture, or kill any marine mammal. "Harassment" is defined as any act of pursuit, torment, or annoyance which has the potential to injure a marine mammal in the wild, or has the potential to disturb a marine mammal in the wild by causing disruption of behavioral patterns, including, but not limited to, migration, breathing, nursing, breeding, feeding, or sheltering. Based on the information included in the draft PEIS, the proposed project may cause take of marine mammals under the jurisdiction of NOAA Fisheries. NOAA Fisheries recommends that the Missile Defense Agency consult with the appropriate NOAA Fisheries Regional Office when conducting the site-specific analyses for potential impacts to marine mammals.

United States Department of the Interior

OFFICE OF THE SECRETARY
Washington, DC 20240

TAKE PRIDE IN AMERICA

NOV 18 2004

ER 04/701

MDA BMDS PEIS
C/O ICF Consulting
9300 Lee Highway
Fairfax, VA 22031

Ladies/Gentlemen:

The United States Department of the Interior has reviewed the Department of the Defense, Missile Defense Agency's (MDA) draft programmatic environmental impact statement (DPEIS) for the Ballistic Missile Defense System (BMDS) and offers the following comments.

Air Quality and Pollution

The Department's National Park Service (NPS) commends the MDA for recognizing that review requirements under the National Environmental Policy Act (NEPA) are not the same as those involving conformity and its willingness to comply with both NEPA and the conformity regulations. The Department also commends the MDA for examining potential impacts on air quality, including its recognition of visibility as an important issue, and looks forward to future reports that include an examination of visibility impacts.

Section 3.1.3 Biological Resources

Pages 3-16 to 3-17: The portion titled "Definition and Description" emphasizes consideration of Federal and State listed species, or species proposed for listing. However, NEPA requires that other species that may be impacted by the proposed activity must also be evaluated throughout the DPEIS. See also page 4-42, subportion "Launch/Flight Activities," where impacts to only species of concern are addressed. We recommend that the DPEIS address all applicable species.

Pages 3-17 to 3-18: In the portion titled "Impact Assessment," we recommend the following text be inserted to address requirements in the referenced laws:

> If the proponent of the proposed activity determines that migratory bird species may be adversely impacted, then the proponent should confer with the Department's Fish and Wildlife Service's (FWS) Regional Migratory Bird Program to ensure

> compliance with the Migratory Bird Treaty Act (MBTA) and the Bald and Golden Eagle Protection Act, where applicable. Under the MBTA, the taking of migratory birds is not authorized without a permit. The project proponent should also confer with the Service to determine if conservation measures may be implemented to minimize or avoid take of migratory birds.

Page 3-19: In the subportion "Determination of Significance," we recommend that reference to the MBTA be incorporated. We also recommend that the final PEIS indicate that military readiness activities implemented in the future by the MDA should be in compliance with the rule currently being finalized by the Service, "Migratory Bird Permits: Take of Migratory Birds by DoD."

Section 3.1.9 Land Use

Page 3-31: In the portion titled "Impact assessment," we suggest referencing the Service National Wildlife Refuges.

Section 4.1.1.1 Weapons – Lasers

Page 4-26: In the portion titled "Biological Resources," under the subportion "Land and Sea Operating Environments," we recommend adding text that indicates that hydrochloric acid could have an effect on shorebirds and waterbirds (in addition to waterfowl, which are already referenced).

Page 4-27: In the last paragraph under the subportion referenced above, we recommend that the text specify the maximum noise level, if available, for which animals "generally return to normal activities within a short time following noise disturbance." Most wildlife has a limited tolerance to noise. We recommend specifying the threshold at which this tolerance level would generally be exceeded and when adverse effects may occur. See also page 4-43 where impacts to birds from noise disturbance are discussed in greater detail. These two sections should be in agreement with each other. The statement on page 4-27 is not in concurrence with the discussions on page 4-43, which indicate there may be more than minor disturbances.

Section 4.1.1.3 Sensors – Radars

Page 4-64 to 4-65: We believe the analysis of impacts on birds from radar in the "Biological Resources" portion is outdated and inadequate. The first paragraph of this portion does not address the potential effects of radar on very large flocks of migrating birds. Even if a bird is not "within the most intense area of the beam for any considerable length of time," there is insufficient evidence to support the statement that no significant adverse impacts to birds would occur. The 1993 report that is referenced to support this conclusion is outdated.

We recommend the analysis describe what constitutes a "relatively small" beam size. A beam going through a dense flock could have an adverse effect on birds, particularly for those species which are already significantly in decline. We recommend that this potential adverse effect be described.

We recommend that this section discuss the potential of using NEXRAD (Next Generation Weather Radar) to help evaluate when large flocks may be in the testing area. NEXRAD could provide valuable information regarding times when testing should not occur to reduce biological impacts. This technology is currently being used by the Air Force to reduce the potential for air strikes and by the Department of Defense to identify important stopover habitat in relation to Department of Defense installations.

We recommend that an avian physiologist, particularly one very knowledgeable of electromagnetic radiation, carefully review the effects of this proposed activity.

In reference to the Cobra Dane study, it should be noted in the DPEIS that arctic foxes, which are very efficient predators, are present on Shemya and other Aleutian Islands, and would quickly remove evidence of any bird kills. Lack of evidence of bird die-offs under these conditions does not provide solid evidence that they aren't occurring.

Bird collisions with radar equipment, particularly towers, can have significant impacts on birds. Estimated annual bird kills from collisions with communication towers (radio, television, cellular, and microwave) range from four- to five-million, both from direct collisions with the towers themselves and with guy wires. Tall radar towers, i.e., those above 199 feet MSL (mean sea level), are of particular concern. The greatest impact occurring from towers illuminated at night with solid or pulsating incandescent red lights. In addition, the potential for tower collisions significantly increases at night under cloudy or otherwise low visibility conditions.

Because of these impacts, the MDA should follow the FWS's "Interim Guidelines For Recommendations On Communications Tower Siting, Construction, Operation, and Decommissioning - 2000," for both existing and proposed radar towers. These guidelines should be referenced in the DPEIS as applying to radar equipment. They also should be applied to Re-Radiation Towers discussed in the second paragraph on page 4-77.

Section 4.1.1.5 Sensors - Laser Sensors

Page 4-73: Under the portion titled "Biological Resources," we have similar concerns for potential impacts on migratory birds from laser sensors as those stated above for radar equipment. This is particularly true for the use of land and sea-based lasers and in situations where large flocks may be present. Although the lasers may not directly hit birds or other wildlife on the ground, impacts to birds in the air could be significant. We recommend that these potential impacts be described.

Regarding the Nominal Ocular Hazard Distance, the DPEIS concludes that impacts to wildlife from a space-based laser sensor would be insignificant because it is unlikely that the laser would be directed towards the Earth's surface and, if it were, distortion from atmospheric conditions would reduce the radiance level. It further concludes that the Earth's surface would likely be beyond the Nominal Ocular Hazard Distance. This conclusion is not well supported. We recommend that the DPEIS identify how "likely" it is that the Earth's surface would not be beyond this specified distance.

Section 4.1.1.9 Support Assets - Infrastructure

Page 4-89 to 4-90: In reference to the first paragraph under "Biological Resources," we note that the construction of infrastructure, depending upon its extent, can significantly increase surface runoff. This can negatively impact surrounding habitats, particularly wetlands and other sensitive habitats. Impacts to fish, wildlife, and plants from pollutants could be more than temporary depending upon the pollutant and length of exposure. Depending upon the species in the project area, construction could have a larger area of disturbance than 50-feet, particularly for nesting bird species. We recommend that this section describe these possible impacts.

We recommend that the second paragraph indicate that site preparation and installation could negatively impact waterbirds utilizing the shore environment, particularly during breeding season.

In the third paragraph, we recommend that the description of behavioral responses to construction include nest abandonment and alteration of migration routes of larger mammals.

We recommend that the fifth paragraph list compliance with the Marine Mammal Protection Act, the Migratory Bird Treaty Act, and the Bald and Golden Eagle Protection Act as required, where applicable. These regulatory references should also be inserted in the portion titled "Biological Resources" under Section 4.1.1.10 Support Assets - Test Assets.

Section 4.1.2.3 Biological Resources

Page 4-105: Under "Integrated Ground Tests," we believe that the conclusion of insignificant impacts is not sufficiently justified or supported. This section lacks information regarding the size and orientation of the operating radar sensors. It also does not describe the anticipated increased number of these operating radar sensors.

Section 4.4 Adverse Environmental Effects That Cannot Be Avoided

Page 4-133: As stated above, we believe that statements of no significant impact are not sufficiently justified or supported. This section indicates Best Management Practices would be implemented to mitigate adverse effects. However, the DPEIS does not provide sufficient information regarding what these measures might be or what would be recommended. In addition, the conclusion that "those [effects] that could not be avoided should not result in a significant impact to the environment" could be viewed as arbitrary since those effects are insufficiently described.

Appendix H Biome Descriptions

Page H-106: We suggest expanding the discussion of "environmentally sensitive habitat" for the savanna biome. Currently, the discussion consists only of the following two sentences: "National parks and reserves have been established to preserve and protect threatened vegetative

and wildlife species in the Savanna Biome. There are several National Wildlife Refuges along the Gulf Coast."

Technical Comments and Suggested Corrections:

Appendix G Applicable Legal Requirements

Page G-10:

- Under the heading United States, in the first line and after the phrase "The Endangered Species Act of 1973" add, "as amended."
- After the phrase "requires all Federal," delete "departments and" so the line reads "requires all Federal agencies to seek."
- In the second line, delete the word "species" after "endangered."
- In the third line, after the phrase "The Secretary of the Interior was directed," insert "by the Endangered Species Act."
- In the fourth line, after the phrase "Endangered species" replace "designation" with "listing."
- In the second paragraph, last line, delete "an adequate" and insert "integrated"; delete the phrase "in place at the sites" and replace it with "determined to be of benefit to the species", so the line reads … "from critical habitat designations if an integrated natural resource management plan is determined to be of benefit to the species."

Appendix H Biome Descriptions

Page H-7:

- The scientific name of the northern sea otter is *Enhydra lutris*, not *Eumetopias jubatus*.

Page H-39:

- In a discussion of the deciduous forest biome in the northeastern States, red spruce and balsam fir forest types are listed. We note that spruce and fir are evergreen conifers, and forests dominated by them are not generally considered components of a deciduous forest biome. We also note that the preceding description of the taiga biome on pages H-16 through H-29 does not refer to balsam fir, its most prevalent tree species.
- Tropical and subtropical moist broadleaf forests are described as components of the biome; as the text notes, these forests are "dominated by semi-evergreen and evergreen tree species" and thus may be out of place in discussion of a deciduous forest biome.

- A list of examples of "threatened and endangered vegetation [sic]" in this biome includes three species from the eastern and southern U.S. and a species of moss endemic to evergreen (not deciduous) forest on the island of Madeira, which may not be the best grouping of examples to illustrate listed species in the "inland deciduous forest biome."

Page H-40:

- The discussion of wildlife of the deciduous forest biome indicates that the Florida panther "…inhabit[s] the lower coastal plains and flatlands of the middle portion of this biome." The Florida panther is found only in peninsular Florida, which would not be considered the middle portion of this biome. We suggest making this clear or deleting reference to the Florida panther is this statement.

Page H-41:

- A list of threatened and endangered wildlife includes the American black bear as if it were listed range wide; however, it is the Louisiana subspecies (*Ursus americanus luteolus*) that is actually listed as Federally threatened. *Ursus americanus* is listed as threatened due to "similarity of appearance (T (S/A))" throughout the historic range of the Louisiana black bear, which includes Louisiana, Texas, and Mississippi and is, therefore, subject to a special rule as outlined in 50 CFR 17.40(i). The black bear is not federally listed throughout the remainder of its range.
- The species *Achatinella mustelina* is attributed to hammocks in the Everglades; however, it is a snail endemic to tropical evergreen forests in Hawaii.
- The West Indian manatee is incorrectly given the scientific name of an African species (*Trichechus senegalensis*). It is correctly identified as *Trichechus manatus* in Exhibit H-6 on page H-42.

Page H-42:

- The scientific name of the leatherback sea turtle is *Dermochelys coriacea*, the DPEIS incorrectly identifies its scientific name as *Ammospiza caudacuta*.

Page H-43:

- Gorillas are incorrectly listed as inhabitants of East Asian tropical and subtropical moist forest.

Page H-90:

- *Ostrya virginiana* is given as the scientific name of the ironwood introduced on Pacific islands. However, this is a species of eastern North America; it is likely the author had in mind a species of *Casuarina*, also commonly known as ironwood.

Page H-93:

- *Esox lucius*, the northern pike, is attributed to offshore areas near the Pacific Missile Range on Kauai; however, this species is not found in the waters around the Hawaiian Islands. It is likely the author had a different species in mind.

Page H-104:

- In a discussion of the savanna biome, the harpy eagle is listed as one of its "common bird species." However, this eagle is an extremely rare bird of deep forest habitats.

We appreciate the opportunity to provide these comments. Should you have any questions, please do not hesitate to contact Vijai Rai, Team Leader, Natural Resources Management Team, Office of Environmental Policy and Compliance at (202) 208-6661.

Sincerely,

Willie R. Taylor
Director
Office of Environmental
Policy and Compliance

OFFICE OF
ENFORCEMENT AND
COMPLIANCE ASSURANCE

November 17, 2004

Missile Defense Agency
Ballistic Missile Defense System PEIS
c/o ICF Consulting
9300 Lee Highway
Fairfax, VA 22031

Dear Mr. Lehner:

In accordance with our responsibilities under Section 309 of the Clean Air Act and the National Environmental Policy Act (NEPA), the Environmental Protection Agency (EPA) has reviewed the Missile Defense Agency's (MDA) Ballistic Missile Defense System (BMDS) Draft Programmatic Environmental Impact Statement (DPEIS) (CEQ # 040438).

The DPEIS identifies, evaluates and documents, at the programmatic level, the potential environmental impacts of activities associated with the development, testing, deployment, and planning for the eventual decommissioning of the BMDS. It considers the current technology components, support assets, and programs that make up the proposed BMDS as well as the development and application of new technologies.

EPA commends the efforts that MDA has commenced in producing such a comprehensive and well organized document. We also appreciate your efforts in utilizing the extensive environmental analysis that is available for many of the existing components of the proposed BMDS. Based on our review of the DPEIS, we have rated the document as LO - Lack of Objections (see attached "Summary of EPA Rating System"). Although EPA has no objections to the proposed action, there are a few issues that should be clarified.

1) General Comments:

a. To assess the impacts of implementing the proposed BMDS, the DPEIS characterized the existing condition of the affected environment in the locations where various BMDS implementation activities are proposed to occur. MDA has determined that activities associated with the proposed BMDS might occur in locations around the world. Therefore, the affected environment has been considered in terms of global biomes, broad ocean areas, and the atmosphere. This has resulted in the DPEIS being very conceptual and general in nature. EPA understands that once potential BMDS locations are determined, more detailed site-specific documents will be prepared. Through the discussions on the "block approach" or the "block development process", the DPEIS has given clear indications of when follow-on NEPA analysis will occur. We agree with this approach. However, while the documents give representative examples of past, current, or proposed locations where proposed activities may occur within each biome, EPA recommends that the EIS discuss the criteria that MDA will use in making future decisions for site-specific locations.

b. The resource areas considered in this analysis are those resources that MDA believes can potentially be affected by implementing the proposed BMDS. EPA agrees that some resource areas are site-specific or local in nature and, therefore, cannot be effectively analyzed in this type of programmatic document and that the potential impacts on these resources are more appropriately discussed in subsequent site-specific documentation tiered from this PEIS. However, EPA recommends that the final document discuss the existence of multiple species habitat conservation planning efforts that are proximate to DoD lands and the potential impacts of debris on marine and aquatic ecosystems.

c. As suggested by CEQ regulations, MDA has taken advantage of the extensive environmental analyses that already exist for many of the existing components of the proposed BMDS by incorporating these materials into the DPEIS by reference. However, some of these documents are greater than 10 years old. The PEIS should confirm the validity of the information in these documents.

2) Perchlorate Comment: Because there have been differing interpretations of the science associated with the impact on human health from low level exposure to perchlorate and in the interest of resolving scientific questions, EPA, the Department of Defense, the Department of Energy, and the National Aeronautics and Space Administration - members of a broader Interagency Working Group on Perchlorate led by the Office of Science and Technology Policy - have referred scientific issues and EPA's 2002 Draft Health Assessment on Perchlorate to the National Academy of Science (NAS) for review. NAS is currently conducting a study to determine the best science and model to use for determining the health impacts and standards for perchlorate. A report on this study is expected to be completed by the end of 2004. EPA recommends that the results of the report be incorporated into the FPEIS.

We appreciate the opportunity to review this DPEIS. We also look forward to reviewing the FPEIS related to this project. The staff contact for the review is Marthea Rountree and she can be reached at (202) 564-7141.

Sincerely,

for

Anne Norton Miller
Director
Office of Federal Activities

Enclosure: Summary of Rating Definitions

SUMMARY OF EPA RATING SYSTEM

Rating the Environmental Impact of the Action

- **LO (Lack of Objections)** The review has not identified any potential environmental impacts requiring substantive changes to the preferred alternative. The review may have disclosed opportunities for application of mitigation measures that could be accomplished with no more than minor changes to the proposed action.
- **EC (Environmental Concerns)** The review has identified environmental impacts that should be avoided in order to fully protect the environment. Corrective measures may require changes to the preferred alternative or application of mitigation measures that can reduce the environmental impact.
- **EO (Environmental Objections)** The review has identified significant environmental impacts that should be avoided in order to adequately protect the environment. Corrective measures may require substantial changes to the preferred alternative or consideration of some other project alternative (including the no action alternative or a new alternative). The basis for environmental objections can include situations:
    1. *Where an action might violate or be inconsistent with achievement or maintenance of a national environmental standard;*
    2. *Where the Federal agency violates its own substantive environmental requirements that relate to EPA's areas of jurisdiction or expertise;*
    3. *Where there is a violation of an EPA policy declaration;*
    4. *Where there are no applicable standards or where applicable standards will not be violated but there is potential for significant environmental degradation that could be corrected by project modification or other feasible alternatives; or*
    5. *Where proceeding with the proposed action would set a precedent for future actions that collectively could result in significant environmental impacts.*
- **EU (Environmentally Unsatisfactory)** The review has identified adverse environmental impacts that are of sufficient magnitude that EPA believes the proposed action must not proceed as proposed. The basis for an environmentally unsatisfactory determination consists of identification of environmentally objectionable impacts as defined above and one or more of the following conditions:
    1. *The potential violation of or inconsistency with a national environmental standard is substantive and/or will occur on a long-term basis;*
    2. *There are no applicable standards but the severity, duration, or geographical scope of the impacts associated with the proposed action warrant special attention; or*
    3. *The potential environmental impacts resulting from the proposed action are of national importance because of the threat to national environmental resources or to environmental policies.*

Adequacy of the Impact Statement

- **Category 1 (Adequate)** The draft EIS adequately sets forth the environmental impact(s) of the preferred alternative and those of the alternatives reasonably available to the project or action. No further analysis or data collection is necessary, but the reviewer may suggest the addition of clarifying language or information.
- **Category 2 (Insufficient Information)** The draft EIS does not contain sufficient information to fully assess environmental impacts that should be avoided in order to fully protect the environment, or the reviewer has identified new reasonably available alternatives that are within the spectrum of alternatives analyzed in the draft EIS, which could reduce the environmental impacts of the proposal. The identified additional information, data, analyses, or discussion should be included in the final EIS.
- **Category 3 (Inadequate)** The draft EIS does not adequately assess the potentially significant environmental impacts of the proposal, or the reviewer has identified new, reasonably available, alternatives, that are outside of the spectrum of alternatives analyzed in the draft EIS, which should be analyzed in order to reduce the potentially significant environmental impacts. The identified additional information, data, analyses, or discussions are of such a magnitude that they should have full public review at a draft stage. This rating indicates EPA's belief that the draft EIS does not meet the purposes of NEPA and/or the Section 309 review, and thus should be formally revised and made available for public comment in a supplemental or revised draft EIS.

K.5.2 Responses to Federal Agency Comments

The following comments and responses in Exhibit K-6 are organized by issue topics, including BMDS, Biological Resources, etc. The comment number includes the comment document number and the sequential number of the comment. For E0001-2, "E0001" refers to the comment document number and "2" refers to the sequential comment number.

Exhibit K-6. Responses to Federal Agency Comments

Issue Topic	Comment Number	Excerpt Text	Response
BMDS	F0003-1 and M0276-1	To assess the impacts of implementing the proposed BMDS, the DPEIS characterized the existing condition of the affected environment in the locations where various BMDS implementation activities are proposed to occur. MDA has determined that activities, associated with the proposed BMDS might occur in locations around the world. Therefore, the affected environment has been considered in terms of global biomes, broad ocean areas, and the atmosphere. This has resulted in the DPEIS being very conceptual and general in nature. EPA understands that once potential BMDS locations are determined, more detailed site-specific documents will be prepared. Through the discussions on the "block approach" or the "block development process", the DPEIS has given clear indications of when follow-on NEPA analysis will occur. We agree with this approach. However, while the documents give representative examples of past, current, or proposed locations where proposed activities may occur within each biome, EPA recommends that the EIS discuss the criteria that MDA will use in making future decisions for site-specific locations.	The MDA will continue to develop test scenarios that will allow for realistic testing of the proposed BMDS. In so doing, the MDA will consider the objectives of the proposed test, the BMDS assets required/available, and potential suitable locations to meet test objectives within acceptable safety, environment, schedule, and cost-effectiveness parameters. MDA uses both DoD and commercial launch facilities and ranges to facilitate and support its test program. MDA also considers targets of opportunity (i.e., piggy-backing components on the back of other tests) when planning its testing to optimize the use of other DoD or component-specific testing to play (i.e., testing target discrimination, track and potential intercept) or watch (i.e., testing data discrimination, tracking, and interpretation capabilities of various components). MDA-sponsored tests receive NEPA consideration and determination prior to conduct of testing.
Biological Resources	F0006-3	Whales, dolphins, seals, and sea lions are protected under the Marine Mammal Protection Act (MMPA).	On January 14, 2004 MDA representatives met with NOAA Fisheries Service personnel to discuss

Exhibit K-6. Responses to Federal Agency Comments

Issue Topic	Comment Number	Excerpt Text	Response
		Under the MMPA, "take" of a small number of marine mammals is permitted by NOAA Fisheries under an Incidental Harassment Authorization (IHA) when the specified activity is incidental, but not intentional. "Take" is defined as harassing, hunting, capturing, or killing, or attempting to harass, hunt, capture, or kill any marine mammal. "Harassment" is defined as any act of pursuit, torment, or annoyance which has the potential to injure a marine mammal in the wild, or has the potential to disturb a marine mammal in the wild by causing disruption of behavioral patterns, including, but not limited to, migration, breathing, nursing, breeding, feeding, or sheltering. Based on the information included in the draft PEIS, the proposed project may cause take of marine mammals under the jurisdiction of NOAA Fisheries. NOAA Fisheries recommends that the Missile Defense Agency consult with the appropriate NOAA Fisheries Regional Office when conducting the site-specific analyses for potential impacts to marine mammals.	programmatic consultation pertaining to the BMDS PEIS. If site-specific analyses indicate the potential for BMDS activities to result in a "take" of species protected under the Marine Mammal Protection Act, the project proponent will consult with the NOAA Fisheries Service Regional Office, as appropriate.
Biological Resources	M0275-1	Pages 3-16 to 3-17: The portion titled "Definition and Description" emphasizes consideration of Federal and State listed species, or species proposed for listing. However, NEPA requires that other species that may be impacted by the proposed activity must also be evaluated throughout the DPEIS. See also page 4-42, subportion "Launch/Flight Activities," where impacts to only species of concern are addressed. We recommend that the DPEIS address all applicable species.	The text in Section 3.1.3 has been modified to reflect that environmental impacts to all species potentially impacted by the activities are considered in the PEIS.

Exhibit K-6. Responses to Federal Agency Comments

Issue Topic	Comment Number	Excerpt Text	Response
Biological Resources	M0275-2	Pages 3-17 to 3-18: In the portion titled "Impact Assessment," we recommend the following text be inserted to address requirements in the referenced laws: If the proponent of the proposed activity determines that migratory bird species may be adversely impacted, then the proponent should confer with the Department's Fish and Wildlife Service's (FWS) Regional Migratory Bird Program to ensure compliance with the Migratory Bird Treaty Act (MBTA) and the Bald and Golden Eagle Protection Act, where applicable. Under the MBTA, the taking of migratory birds is not authorized without a permit. The project proponent should also confer with the Service to determine if conservation measures may be implemented to minimize or avoid take of migratory birds.	Language similar to the recommended text has been added to the PEIS.
Biological Resources	M0275-3	Page 3-19: In the subportion "Determination of Significance," we recommend that reference to the MBTA be incorporated. We also recommend that the final PEIS indicate that military readiness activities implemented in the future by the MDA should be in compliance with the rule currently being finalized by the Service, "Migratory Bird Permits; Take of Migratory Birds by DoD."	Language on the Migratory Bird Treaty Act has been added to the Determination of Significance for Biological Resources. It should be noted that throughout the PEIS references are made to the fact that the project proponent would be required to comply with all applicable regulations. Therefore, specific mention of the "Migratory Bird Permits; Take of Migratory Birds by DoD" currently being finalized has not been added to the PEIS.
Biological Resources	M0275-5	Page 4-26: In the portion titled "Biological Resources," under the subportion "Land and Sea Operating Environments," we recommend adding text that indicates that hydrochloric acid could have an effect on shorebirds and waterbirds (in addition to waterfowl, which are already referenced).	A reference to shorebirds and waterbirds has been added to the discussion on the impacts to birds from hydrochloric acid in water.

Exhibit K-6. Responses to Federal Agency Comments

Issue Topic	Comment Number	Excerpt Text	Response
Biological Resources	M0275-6	Page 4-27: In the last paragraph under the subportion referenced above, we recommend that the text specify the maximum noise level, if available, for which animals "generally return to normal activities within a short time following noise disturbance." Most wildlife has a limited tolerance to noise. We recommend specifying the threshold at which this tolerance level would generally be exceeded and when adverse effects may occur. See also page 4-43 where impacts to birds from noise disturbance are discussed in greater detail. These two sections should be in agreement with each other. The statement on page 4-27 is not in concurrence with the discussions on page 4-43, which indicate there may be more than minor disturbances.	The text has been modified to include details of two studies cited in the 1988 Manci et al report titled "Effects of aircraft noise on domestic animals and wildlife: a literature synthesis." (Manci, K.M., D.N. Gladwin, R. Villella, and M.G. Cadendish. 1988. Effects of aircraft noise on domestic animals and wildlife: a literature synthesis. USFWS. National Ecology Research Center, Ft. Collins, CO. NERC-88/29) Specifically, a 1982 study by Stewart (Stewart, B.S. 1982. Studies on the Pinnipeds of the Southern California Channel Islands, 1980-1981. Hubbs-Sea World Research Institute, San Diego, CA Tech Report No 82-136 as cited in Manci et al, 1988) and a 1980 study by Jehl and Cooper. (Jehl, J.R. and C.F. Cooper, eds. 1980. Potential effects of Space Shuttle booms on the biota and geology of the California Channel Islands. Research Reports Center for Marine Studies, San Diego State University, San Diego, CA. Tech Report 80-1 as cited in Manci et al, 1988)
Biological Resources	M0275-7	Page 4-64 to 4-65: We believe the analysis of impacts on birds from radar in the "Biological Resources" portion is outdated and inadequate. The first paragraph of this portion does not address the potential effects of radar on very large flocks of migrating birds. Even if a bird is not "within the most intense area of the beam for any considerable length of time," there is insufficient evidence to support the statement that no significant adverse impacts to birds would occur. The 1993 report that is referenced to support this conclusion is outdated.	In response to the Department of Interior comments regarding impacts to biological resources from radar, the MDA conducted an analysis of the potential for impact from proposed BMDS radars on migratory birds. This analysis is included in Appendix N of this PEIS. Appendix N responds to Department of Interior concerns regarding the conclusions reached in the 1993 EA and introduces possible mitigation measures.

Exhibit K-6. Responses to Federal Agency Comments

Issue Topic	Comment Number	Excerpt Text	Response
Biological Resources	M0275-8	Bird collisions with radar equipment, particularly towers, can have significant impacts on birds. Estimated annual bird kills from collisions with communication towers (radio, television, cellular, and microwave) range from four- to five-million, both from direct collisions with the towers themselves and with guy wires. Tall radar towers, i.e., those above 199 feet MSL (mean sea level), are of particular concern. The greatest impact occurring from towers illuminated at night with solid or pulsating incandescent red lights. In addition, the potential for tower collisions significantly increases at night under cloudy or otherwise low visibility conditions. Because of these impacts, the MDA should follow the FWS's "Interim Guidelines For Recommendations On Communications Tower Siting, Construction, Operation, and Decommissioning - 2000," for both existing and proposed radar towers. These guidelines should be referenced in the DPEIS as applying to radar equipment. They also should be applied to Re-Radiation Towers discussed in the second paragraph on page 4-77.	MDA would follow or intend to follow all relevant and applicable USFWS Guidelines whether interim or not and indicate that all applicable environmental, health and safety rules and regulations are scrupulously adhered to during MDA siting, construction, operation and decommissioning.
Biological Resources	M0275-9	Page 4-73: Under the portion titled "Biological Resources," we have similar concerns for potential impacts on migratory birds from laser sensors as those stated above for radar equipment. This is particularly true for the use of land and sea-based lasers and in situations where large flocks may be present. Although the lasers may not directly hit birds or other wildlife on the ground, impacts to birds in the air	The potential for impacts or eye injuries to biological resources including migratory birds from laser sensor activation has been characterized and described in a level of detail commensurate with the potential for impact to these resources.

Exhibit K-6. Responses to Federal Agency Comments

Issue Topic	Comment Number	Excerpt Text	Response
		could be significant. We recommend that these potential impacts be described.	
Biological Resources	M0275-10	Regarding the Nominal Ocular Hazard Distance, the DPEIS concludes that impacts to wildlife from a space-based laser sensor would be insignificant because it is unlikely that the laser would be directed towards the Earth's surface and, if it were, distortion from atmospheric conditions would reduce the radiance level. It further concludes that the Earth's surface would likely be beyond the Nominal Ocular Hazard Distance. This conclusion is not well supported. We recommend that the DPEIS identify how "likely" it is that the Earth's surface would not be beyond this specified distance.	ANSI Z136.1 Safe Use of Lasers provides tables to determine the Maximum Permissible Exposure Limit (MPE) based on the wavelength, duration of exposure, and correction factors. Laser range equations are used to calculate the Nominal Ocular Hazard Distance (NOHD) based on the laser sensor MPE, classification, categorization, and other applicable laser operating characteristics. If the calculated distance of NOHD is below the Earth's surface for a space-based laser sensor to reach, the impact of that space-based laser sensor would be insignificant on the Earth surface. If specific space-based laser sensors were proposed to be used as part of the BMDS, the MDA would perform the necessary calculations to determine the NOHD. However, in general it is expected that the NOHD for space-based laser sensors would not intersect the Earth's surface.
Biological Resources	M0275-11	▪ Page 4-89 to 4-90: In reference to the first paragraph under "Biological Resources," we note that the construction of infrastructure, depending upon its extent, can significantly increase surface runoff. This can negatively impact surrounding habitats, particularly wetlands and other sensitive habitats. Impacts to fish, wildlife, and plants from pollutants could be more than temporary depending upon the pollutant and length of exposure. Depending upon the species in the project area, construction could have a larger area of disturbance than 50-feet, particularly for	▪ Language on the potential for surface runoff has been added to the PEIS. It should be noted that impacts to particular species from specific pollutants or construction projects would need to be considered in site-specific documentation.

Exhibit K-6. Responses to Federal Agency Comments

Issue Topic	Comment Number	Excerpt Text	Response
		nesting bird species. We recommend that this section describe these possible impacts. ▪ We recommend that the second paragraph indicate that site preparation and installation could negatively impact waterbirds utilizing the shore environment, particularly during breeding season. ▪ In the third paragraph, we recommend that the description of behavioral responses to construction include nest abandonment and alteration of migration routes of larger mammals.	▪ A reference to waterbirds has been added to the discussion on the impacts to species from site preparation and installation of underground cable. ▪ Language similar to the recommended text regarding possible behavioral responses including nest abandonment and alteration of migration routes has been added to the PEIS.
Biological Resources	M0275-12	We recommend that the fifth paragraph list compliance with the Marine Mammal Protection Act, the Migratory Bird Treaty Act, and the Bald and Golden Eagle Protection Act as required, where applicable. These regulatory references should also be inserted in the portion titled "Biological Resources" under Section 4.1.1.10 Support Assets - Test Assets.	Language similar to the recommended text regarding inclusion of the Marine Mammal Protection Act, Migratory Bird Treaty, and Bald and Golden Eagle Protection Act has been added to the PEIS.
Biological Resources	M0275-13	Page 4-105: Under "Integrated Ground Tests," we believe that the conclusion of insignificant impacts is not sufficiently justified or supported. This section lacks information regarding the size and orientation of the operating radar sensors. It also does not describe the anticipated increased number of these operating radar sensors.	The PEIS is a programmatic environmental analysis. The PEIS does not consider the operation of specific sensors or specific activation orientations for these sensors. In response to comments MDA added technical Appendix N, Impacts of Radar on Wildlife to the PEIS. Based on the information analyzed as part of the sensor component discussion, the analyses incorporated by reference, and the technical analyses in Appendix N in this PEIS, there is no indication that operating multiple sensors in a single biome would produce significant impacts on biological resources. The MDA believes that

Exhibit K-6. Responses to Federal Agency Comments

Issue Topic	Comment Number	Excerpt Text	Response
			based on the information presented in this PEIS and on the information and analyses incorporated by reference, the expectation of insignificant impacts to biological resources from integrated ground tests is supported in the PEIS. However, it should be noted that test-specific analyses would be prepared to determine whether the potential for significant impacts exists for a specific test scenario.
Biological Resources	M0275-14	Page 4-133: As stated above, we believe that statements of no significant impact are not sufficiently justified or supported. This section indicates Best Management Practices would be implemented to mitigate adverse effects. However, the DPEIS does not provide sufficient information regarding what these measures might be or what would be recommended. In addition, the conclusion that "those [effects] that could not be avoided should not result in a significant impact to the environment" could be viewed as arbitrary since those effects are insufficiently described.	Section 4.4 of the PEIS states that "Adverse environmental effects that cannot be avoided include the removal of vegetation during site preparation and construction activities; minor short-term noise impacts startling of wildlife; deposition of small amounts of pollutants on land, air, and sea; minor increased generation of hazardous materials; and emission of EMR." This Section of the PEIS further states that these effects are not expected to result in significant impact to the environment. These effects were described in Sections 4.1.1.1 through 4.3 and on a programmatic level were found to have no significant impact to the environment. The PEIS is intended to serve as a tiering document for future site-specific analyses. These site-specific analyses would determine whether site or test specific characteristics would lead to a potentially significant impact. These impacts will be appropriately considered in these tiered analyses. The tiered analyses may also consider specific mitigation measures including Best Management Practices that are appropriate for the action or test under consideration.

Biological Resources	M0275-27	A list of threatened and endangered wildlife includes the American black bear as if it were listed range wide; however, it is the Louisiana subspecies {Ursus americanus luteolus) that is actually listed as Federally threatened. Ursus americanus is listed as threatened due to "similarity of appearance (T (S/A))" throughout the historic range of the Louisiana black bear, which includes Louisiana, Texas, and Mississippi and is, therefore, subject to a special rule as outlined in 50 CFR 17.40(i). The black bear is not federally listed throughout the remainder of its range.	The reference to the American black bear has been removed. It should be noted that the species listed in Appendix H are examples of species that are listed as threatened or endangered in the Deciduous forest biome.
Biological Resources	M0275-28	The species Achatinella mustelina is attributed to hammocks in the Everglades; however, it is a snail endemic to tropical evergreen forests in Hawaii.	The reference to Achatinella mustelina has been removed.
Biological Resources	M0275-29	The West Indian manatee is incorrectly given the scientific name of an African species {Trichechus senegalensis). It is correctly identified as Trichechus manatus in Exhibit H-6 on page H-42.	The reference to the West Indian manatee's scientific name has been corrected.
Biological Resources	M0275-30	The scientific name of the leatherback sea turtle is Dermochelys coriacea, the DPEIS incorrectly identifies its scientific name as Ammospiza caudacuta.	The reference to the leatherback sea turtle's scientific name has been corrected.
Biological Resources	M0275-31	Gorillas are incorrectly listed as inhabitants of East Asian tropical and subtropical moist forest.	The reference to gorillas living in the East Asian tropical and subtropical moist broadleaf forests has been removed.
Biological Resources	M0275-32	Ostrya virginiana is given as the scientific name of the ironwood introduced on Pacific islands. However, this is a species of eastern North America; it is likely the author had in mind a species of Casuarina, also commonly known as ironwood.	The reference to Ostrya virginiana as being the scientific name of ironwood species introduced on Pacific islands has been removed.
Biological Resources	M0275-33	Esox lucius, the northern pike, is attributed to offshore areas near the Pacific Missile Range on Kauai;	The reference to Esox lucius has been removed.

Exhibit K-6. Responses to Federal Agency Comments

Issue Topic	Comment Number	Excerpt Text	Response
		however, this species is not found in the waters around the Hawaiian Islands. It is likely the author had a different species in mind.	
Biological Resources	M0275-34	In a discussion of the savanna biome, the harpy eagle is listed as one of its "common bird species." However, this eagle is an extremely rare bird of deep forest habitats.	The reference to the harpy eagle being a "common bird species" of the savanna biome has been removed.
Biological Resources – Debris Impacts	F0003-2 and M0276-2	The resource areas considered in this analysis are those resources that MDA believes can potentially be affected by implementing the proposed BMDS. EPA agrees that some resource areas are site-specific or local in nature and, therefore, cannot be effectively analyzed in this type of programmatic document and that the potential impacts on these resources are more appropriately discussed in subsequent site-specific documentation tiered from this PEIS. However, EPA recommends that the final document discuss the existence of multiple species habitat conservation planning efforts that are proximate to DoD lands and the potential impacts of debris on marine and aquatic ecosystems.	The potential impacts of debris in marine and aquatic ecosystems were considered as part of Postlaunch Activities for each resource area analyzed in the PEIS. These discussions highlighted the potential programmatic environmental impacts from launch debris impacting in water environments. Although it would not be appropriate to discuss specific multiple species habitat conservation areas that are proximate to DoD lands in this programmatic document, a statement about multiple species habitat conservation planning efforts has been added to Section 3.2.3 of the PEIS.
Hazardous Materials Hazardous Waste	F0006-1	NOAA Fisheries recommends that the Missile Defense Agency be responsible for handling and disposing of all hazardous materials or hazardous wastes in all phases of the proposed action in accordance with applicable Federal, state, and local laws, utilizing best management practices at all life cycle activities of the proposed action and through appropriate project planning and design measures including appropriate spill prevention, control and	The disposal of all hazardous materials and hazardous wastes would be conducted in compliance with applicable Federal, state, and local laws. Project planning would take spill prevention, control, and contingency planning into account to ensure compliance with all relevant regulations.

Exhibit K-6. Responses to Federal Agency Comments

Issue Topic	Comment Number	Excerpt Text	Response
		contingency plans (e.g., Oil Discharge Prevention and Contingency Plan, Storm Water Pollution Prevention Plan) for each site.	
Perchlorate	F0003-4 and M0276-4	Perchlorate Comment: Because there have been differing interpretations of the science associated with the impact on human health from low level exposure to perchlorate and in the interest of resolving scientific questions, EPA, the Department of Defense, the Department of Energy, and the National Aeronautics and Space Administration - members of a broader Interagency Working Group on Perchlorate led by the Office of Science and Technology Policy -have referred scientific issues and EPA's 2002 Draft Health Assessment on Perchlorate to the National Academy of Science (NAS) for review. NAS is currently conducting a study to determine the best science and model to use for determining the health impacts and standards for perchlorate. A report on this study is expected to be completed by the end of 2004. EPA recommends that the results of the report be incorporated into the FPEIS.	In addition to citing the Perchlorate Study Group findings, the Final PEIS has been modified to include the proposed findings from the State of California Office of Environmental Health Hazard Assessment, the State of Massachusetts, and U.S. EPA. The results of relevant reports and findings completed prior to the finalization and publication of the PEIS were included as appropriate. The proposed BMDS activities would need to comply with all applicable regulations including any regulations issued regarding perchlorate levels. To better characterize some of the potential impacts associated with proposed BMDS activities, additional information and research on perchlorate has been added to Section 4.1.1.2 of the Final PEIS. Further, a technical appendix (see Appendix M) addressing issues specifically related to perchlorate has been added to the Final PEIS. The appendix considers the uses, sources, and disposal of perchlorate as well as the effects on human health and the environment.

Editorial	M0275-19	In the third line, after the phrase "The Secretary of the Interior was directed," insert "by the Endangered Species Act."	Editorial and other text modifications made as requested.
Editorial	M0275-20	In the fourth line, after the phrase "Endangered species" replace "designation" with "listing."	Editorial and other text modifications made as requested.
Editorial	M0275-21	In the second paragraph, last line, delete "an adequate" and insert "integrated"; delete the phrase "in place at the sites" and replace it with "determined to be of benefit to the species", so the line reads…"from critical habitat designations if an integrated natural resource management plan is determined to be of benefit to the species." Modification made as requested.	Editorial and other text modifications made as requested.
Editorial	M0275-22	The scientific name of the northern sea otter is Enhydra lutris, not Eumetopias jubatus.	Editorial and other text modifications made as requested.
Affected Environment	M0275-15	Page H-106: We suggest expanding the discussion of "environmentally sensitive habitat" for the savanna biome. Currently, the discussion consists only of the following two sentences: "National parks and reserves have been established to preserve and protect threatened vegetative and wildlife species in the Savanna Biome. There are several National Wildlife Refuges along the Gulf Coast."	Editorial and other text modifications made as requested.
Affected Environment	M0275-23	In a discussion of the deciduous forest biome in the northeastern States, red spruce and balsam fir forest types are listed. We note that spruce and fir are evergreen conifers, and forests dominated by them are not generally considered components of a deciduous forest biome. We also note that the preceding description of the taiga biome on pages H-16 through	Editorial and other text modifications made as requested.

Exhibit K-6. Responses to Federal Agency Comments

Issue Topic	Comment Number	Excerpt Text	Response
		H-29 does not refer to balsam fir, its most prevalent tree species.	
Affected Environment	M0275-24	Tropical and subtropical moist broadleaf forests are described as components of the biome; as the text notes, these forests are "dominated by semi-evergreen and evergreen tree species" and thus may be out of place in discussion of a deciduous forest biome.	Editorial and other text modifications made as requested.
Affected Environment	M0275-25	A list of examples of "threatened and endangered vegetation [sic]" in this biome includes three species from the eastern and southern U.S. and a species of moss endemic to evergreen (not deciduous) forest on the island of Madeira, which may not be the best grouping of examples to illustrate listed species in the "inland deciduous forest biome."	Editorial and other text modifications made as requested.
Affected Environment	M0275-26	The discussion of wildlife of the deciduous forest biome indicates that the Florida panther"... inhabit[s] the lower coastal plains and flatlands of the middle portion of this biome." The Florida panther is found only in peninsular Florida, which would not be considered the middle portion of this biome. We suggest making this clear or deleting reference to the Florida panther is this statement.	Editorial and other text modifications made as requested.
NEPA Process	F0006-2	Based on the information provided in the draft PEIS, NOAA Fisheries recommends that the Missile Defense Agency consult with the appropriate NOAA Fisheries Regional Office to determine if listed species under the Endangered Species Act (ESA) of 1973 as amended (16.U.S.C. 1531 et. seq.) may be affected by the proposed project. If it is determined that this project may affect a listed or proposed species, the Missile Defense Agency should request	On January 14, 2004 MDA representatives met with NOAA Fisheries Service personnel to discuss programmatic consultation pertaining to the BMDS PEIS. If site-specific analyses indicate the potential for BMDS activities to result in a "take" of species protected under the Endangered Species Act of 1973 as amended (16.U.S.C. 1531 et. seq.), the project proponent will consult with the NOAA Fisheries Service Regional Office, as appropriate.

Exhibit K-6. Responses to Federal Agency Comments

Issue Topic	Comment Number	Excerpt Text	Response
		initiation of consultation with NOAA Fisheries pursuant to section 7 of the ESA.	
	F0003-3 and M0276-3	As suggested by CEQ regulations, MDA has taken advantage of the extensive environmental analyses that already exist for many of the existing components of the proposed BMDS by incorporating these materials into the DPEIS by reference. However, some of these documents are greater than 10 years old. The PEIS should confirm the validity of the information in these documents.	In accordance with 40 CFR § 1502.21, Incorporation by Reference, information that was incorporated by reference in the PEIS has been cited and briefly described in the PEIS and made available during the public review period. The MDA has reviewed the portions of the information from these documents that are incorporated by reference and found them to be valid and relevant to this PEIS.

APPENDIX L
ORBITAL DEBRIS TECHNICAL APPENDIX

ORBITAL DEBRIS TECHNICAL APPENDIX

L.1 Introduction

This appendix defines orbital debris, discusses its source, fate and disposal options, presents an overview of policies and regulations associated with orbital debris, and concludes with how the MDA addresses orbital debris. This appendix is organized as follows:

- Background information, including definitions and descriptions, fate and disposal options, and ground-based tracking and monitoring
- Current standards and policies, including those implemented by the DoD, NASA and the U.S. Strategic Command (USSTRATCOM)
- MDA activities that produce orbital debris and MDA's coordination with appropriate agencies (e.g., USSTRATCOM and NASA)
- References

L.2 Background Information

This section defines and describes orbital debris. The fate of orbital debris and options for its disposal are discussed, as well as measurements and other data associated with the ground-based tracking and monitoring of orbital debris.

L.2.1 Definition and Description

Orbital debris as considered in this appendix is man-made material that is in orbit around the Earth but no longer serves any useful purpose. This definition excludes the large amount of background or natural space debris (i.e., asteroids and comets) resident in space. Natural space debris occurs in densities several orders of magnitude greater than man-made space debris.

Orbital debris includes such objects as

- Discarded hardware (e.g., upper stages from launch vehicles),
- Abandoned satellites,
- Separations of spacecraft (e.g., bolts, adaptor shrouds),
- Material degradation (e.g., paint flakes, bits of insulation), and
- Object breakup (more than 124 have been identified).

NASA has defined four types of orbital debris

- Large objects that are larger than 10 centimeters (4 inches) in diameter and are routinely detected, tracked, and catalogued;
- Risk objects between one centimeter (0.4 inch) and 10 centimeters (4 inches) in diameter, which cannot be tracked and catalogued;
- Small debris that is between one centimeter (0.4 inch) and one millimeter (0.04 inch) in diameter; and
- Micro debris which is smaller than one millimeter (0.04 inch) in diameter.

The interaction among these four sizes of orbital debris during their time in orbit creates concern that there may be collisions producing additional fragments and causing the total debris population to grow, which may increase the potential for debris reentry into Earth's atmosphere. Debris in each of the four size categories can be divided further into four types depending on its source.

- ***Operational debris*** is composed of inactive payloads and objects released during satellite delivery or satellite operations, including such items as lens caps, separation and packing devices, spin-up mechanisms, empty propellant tanks, spent and intact vehicle bodies, payload shrouds, and a few objects thrown away or dropped during manned activities. (Aerospace Corporation, 2005)

- ***Fragmentation debris*** results from collisions or explosions of objects in space. More than 124 breakups have been verified, and it is estimated that a significant number of others have occurred. (Aerospace Corporation, 2005) Breakups result in the fragmentation of space objects and are generally caused by either the collision of two space objects or an explosion. Explosions cause the majority of breakups. The causes of most explosions can be attributed to

    - Deliberate collisions,
    - Accidental mixing of propellant and oxidizer, and
    - Over-pressurized batteries or propellant (due to heating).

- ***Deterioration debris*** consists of very small debris particles created by the gradual disintegration of spacecraft (e.g., satellites, booster rockets, and manned spacecraft) left on orbit. Material from the spacecraft degrades in space due to atomic oxygen, solar heating, and solar radiation, producing items such as paint flakes, plastic and metal micro debris, and bits of insulation. (Aerospace Corporation, 2005)

- ***Solid rocket motor ejecta*** are typically less than 0.01 centimeter (0.004 inch) in diameter (i.e., micro debris) and result from the ejection of thousands of kilograms of Al_2O_3 particles from SRMs into the orbital environment. (U.S. DOT, 2001) SRMs

used to boost satellite orbits have produced various debris items, including motor casings, aluminum oxide exhaust particles, nozzle slag, motor-liner residuals, solid-fuel fragments, and exhaust cone bits resulting from erosion during the burn. SRMs may release larger chunks of unburned solid propellant or slag produced when most of the solid propellant has been expended and the combustion pressure inside the rocket motor begins to fluctuate or when unspent propellant is expelled into space. However, SRM particles and ejecta typically decay very rapidly or are dispersed by solar radiation pressure. (U.S. DOT, 2001)

Orbital debris generally moves at very high speeds relative to operational satellites. In Low Earth Orbit (LEO), an altitude approximately 1,600 kilometers (1,000 miles) above the surface of the Earth, the average relative velocity at impact is 10 kilometers per second (21,600 miles per hour). At this velocity, even small particles contain significant amounts of kinetic energy and momentum. In GEO, an altitude of approximately 35,000 kilometers (22,000 miles) above the Earth's surface, average relative velocity at impact is much lower than in LEO, about 200 meters per second (432 miles per hour). This is because most objects in GEO move along similar orbits. Nevertheless, fragments at this velocity can still cause considerable damage upon impact. A 10-centimeter (4-inch) fragment in GEO has roughly the same damage potential as a 1-centimeter (0.4-inch) fragment in LEO. A 1-centimeter (0.4-inch) GEO fragment is roughly equivalent to a 1-millimeter (0.04-inch) LEO fragment.

Estimates of the amount of orbital debris vary. According to the NASA Orbital Debris Program Office, approximately 11,000 objects larger than 10 centimeters (4 inches) are known to exist, more than 100,000 particles between one and 10 centimeters (0.4 to 4 inches) in diameter exist, and tens of millions of particles smaller than one centimeter (0.4 inch) exist. (NASA, 2004b) According to the European Space Agency, in 2003 there were approximately 10,000 catalogued debris objects orbiting the Earth. General damage levels associated with the various sizes of debris can be described as follows.

- Debris particles smaller than 1 millimeter (0.04 inch) in size do not generally pose a hazard to spacecraft functionality. However, they can erode sensitive surfaces such as payload optics; thus, while the spacecraft may survive an impact, payload degradation can still result in mission loss.

- Debris fragments from 1 millimeter to 1 centimeter (0.04 to 0.4 inch) in size may or may not penetrate a spacecraft, depending on material selection and whether shielding is used. Penetration through a critical component, such as the flight computer or propellant tank, can result in loss of the spacecraft. On average, debris of one millimeter (0.04 inch) is capable of perforating current U.S. space suits.

- Debris fragments between 1 and 10 centimeters (0.4 to 4 inches) in size will penetrate and damage most spacecraft. If the spacecraft bus is impacted, satellite function will

be terminated and, at the same time a significant amount of small debris will be created. In large satellite constellations, this can lead to amplification of the local smaller debris population and its associated erosion effects.

While it is currently practical to shield or protect spacecraft against debris particles up to one centimeter (0.4 inch) in diameter (a mass of one gram [0.05 ounce]), for larger debris, current shielding concepts become impractical. (NASA, 2003)

Orbital debris also contributes to the larger problem of objects in space, which includes radio-frequency interference and interference with scientific observations in all parts of the spectrum. For example, emissions of debris at radio frequencies often interfere with radio astronomy observations. (NASA, 2003)

Measurements of near-Earth orbital debris are accomplished by conducting ground-based and space-based observations of the orbital debris environment. Data are acquired using ground-based radars and optical telescopes, space-based telescopes, and analysis of spacecraft surfaces returned from space. Some important data sources have been the U.S. Space Surveillance Network (SSN), the Haystack XBR, and returned surfaces from the Solar Max, Long Duration Exposure Facility, and the Space Shuttle spacecraft. The data provide validation of the environment models and identify the presence of new sources of debris. (NASA, 2005)

L.2.2 Fate and Disposal Options

Once orbital debris is formed, it continues to exist in space. Two types of orbits where satellites are stationed and where orbital debris is generated include LEO (see Exhibit L-1) and GEO (see Exhibit L-2). Debris generated at those altitudes would continue orbiting the Earth for extended periods of time (perhaps forever) before the orbit of the debris decays, drawing it closer and closer to Earth. The duration of orbit varies based on the trajectory, velocity, and altitude of an object, with lower altitude orbits decaying faster than high altitude orbits. This is because orbiting objects lose energy through friction with the upper reaches of the atmosphere, which is progressively thinner (less dense) at higher altitudes. Over time, the object falls into progressively lower orbits and eventually falls toward the Earth.

Exhibit L-1. Orbital Debris in LEO

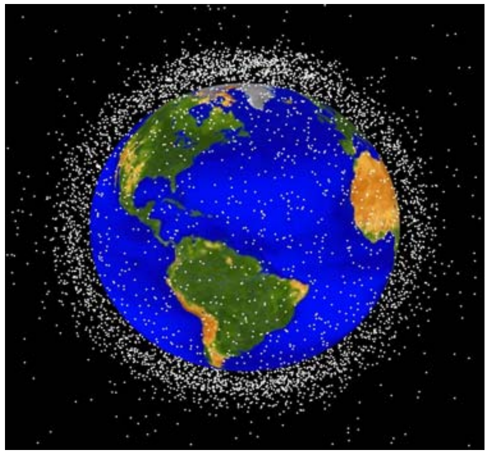

Exhibit L-2. Orbital Debris in GEO

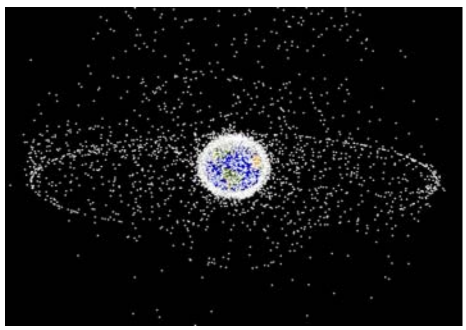


As debris eventually reenters the Earth's atmosphere, it would most likely burn up before reaching the surface of the Earth. This deorbit process limits the lifetime of orbital debris to a maximum of a few days for debris below 200 kilometers (124 miles), a few months for debris originating between 200 kilometers (124 miles) and 400 kilometers (248 miles), a few years between 400 kilometers (248 miles) and 600 kilometers (373 miles), decades between 600 kilometers (373 miles) and 800 kilometers (497 miles), centuries over 800 kilometers (497 miles), and potentially forever if over 36,000 kilometers (22,370 miles). (NASA, 2004a)

The proper disposal of post-mission space structures is critically important to minimizing the amount and future impact of space debris orbiting the Earth. Post-mission space structures are those objects that have been left in space after a mission is complete, and is not planned to be returned to earth (e.g., satellites). Historically, about 2 million kilograms (4.4 million pounds) of space debris has accumulated in orbit because of the practice of abandoning, rather than disposing of, spacecraft at the end of their mission life. (NASA, 1995) This debris poses a threat to continued space operations and increases the likelihood of collisions between two objects in space.

In general, there are three post-mission disposal options available to minimize the creation of orbital debris: (1) direct retrieval and deorbit; (2) reentry disposal; and (3) moving the object to a designated post-mission disposal orbit. (NASA, 1995) Direct retrieval and deorbit refers to retrieving the structure and removing it from orbit at some point after mission completion. Reentry disposal refers to allowing the object to slowly break up as it reenters the Earth's atmosphere. (Patera and Ailor, 1998) "Moving the object…" refers to maneuvering the object to one of a set of disposal orbit regions in which the object will not interfere with future space operations. A disposal orbit region is also known as a graveyard orbit, which is generally a higher altitude orbit where a satellite or other object is placed at the end of its operational life. In a graveyard orbit, a space object is not expected to accidentally collide with an active satellite. However, it is assumed that one day it will eventually reenter Earth's atmosphere and burn up. (Encyclopedia, 2005)

Generally, reentry disposal is not viewed as hazardous to people on Earth because the intense heat generated by atmospheric drag upon reentry is expected to completely destroy the debris. Furthermore, the probability of a surviving piece of the debris striking an inhabited part of the Earth is very low. However, as both the human population on Earth and the number of satellites in the sky increases, the probability of a piece of a reentered satellite randomly striking a population center also increases.

There are two means of disposing of a satellite (or other structure) through reentry breakup: lifetime reduction, which results in a random reentry; and disposal by controlled deorbit, which seeks to target an unpopulated area of the Earth (usually the ocean). (Patera and Ailor, 1998) Lifetime reduction refers to maneuvering the object to an orbit from which atmospheric drag will remove it completely from orbit within 25 years. (NASA, 1995) This approach may result in an uncertain time and place of disposal and makes warning population centers of an impending strike impossible. Disposal by controlled deorbit seeks to guide the structure to a desired impact location through a series of perigee (the point at which the structure is closest to Earth) lowering burns. (Antonio, 2005) This approach is more appropriate than lifetime reduction under the following conditions (Patera and Ailor, 1998)

- The mass of the structure is especially large,
- The structure contains hazardous materials that may pose a safety threat to populations, or
- The structure contains sensitive components that need to be destroyed.

There are a number of options available for disposing an object via moving it to a designated orbital disposal region. These regions are areas of space that are between the three typical areas in which satellites orbit the Earth: LEO, Medium Earth Orbit (semisynchronous) (MEO), and GEO. LEO is the area between the Earth and approximately 1,600 kilometers (1,000 miles) above the Earth; MEO is the area between

around 19,900 and 20,500 kilometers (12,366 and 12,738 miles) above the Earth; and GEO is the area between aproximately 35,0000 and 36,000 kilometers (22,000 and 22,400 miles) above the Earth. (NASA, 1995)

Spacecraft that reenter from either orbital decay or controlled entry usually break up at altitudes between 84 and 72 kilometers (52 and 45 miles) due to aerodynamic forces causing the allowable structural loads to be exceeded. The nominal breakup altitude for spacecraft is considered to be 78 kilometers (48.5 miles). Larger, sturdier, and denser satellites generally break up at lower altitudes. Solar arrays frequently break off the spacecraft parent body around 90 to 95 kilometers (56 to 59 miles) because of the aerodynamic forces causing the allowable bending moment to be exceeded at the array/spacecraft attach point.

Recognizing the growing issue of space debris, both NASA and USSTRATCOM have developed policies to regulate future post-mission disposal of satellites and other space structures. NASA's guidelines provide disposal methods for final mission orbits according to altitude, while USSTRATCOM's policy directive covers the appropriate methods for satellite disposal. Sections 3.1 and 3.2 provide outlines of the policies of both NASA and USSTRATCOM regarding spacecraft or space structure disposal.

L.2.3 Ground-Based Tracking and Monitoring

Ground-based measurements are used to remotely sense the presence of space debris. This is normally done using radar measurements for debris in LEO or optical measurements for debris in GEO. The following characteristics of the debris can be derived from radar measurements (with varying degrees of uncertainty)

- Orbital elements, which describe the motion of the object's center of mass around Earth,
- Attitude, which describes the motion of the object around its center of mass,
- Size and shape,
- Lifetime of the orbit,
- Ballistic coefficient, which specifies the rate at which the orbital semi-major axis decays,
- Mass of the object, and
- Properties of the material.

These data, along with statistical information on the number of objects of a certain size in a certain region over a period of time, are entered into catalogues of space objects. Several catalogues currently track space objects, including the USSTRATCOM catalogue and the space object catalogue of the Russian Federation. Using both of these catalogues, the Database and Information System Characterizing Objects in Space (DISCOS) is updated and maintained by the European Space Agency. Information contained in

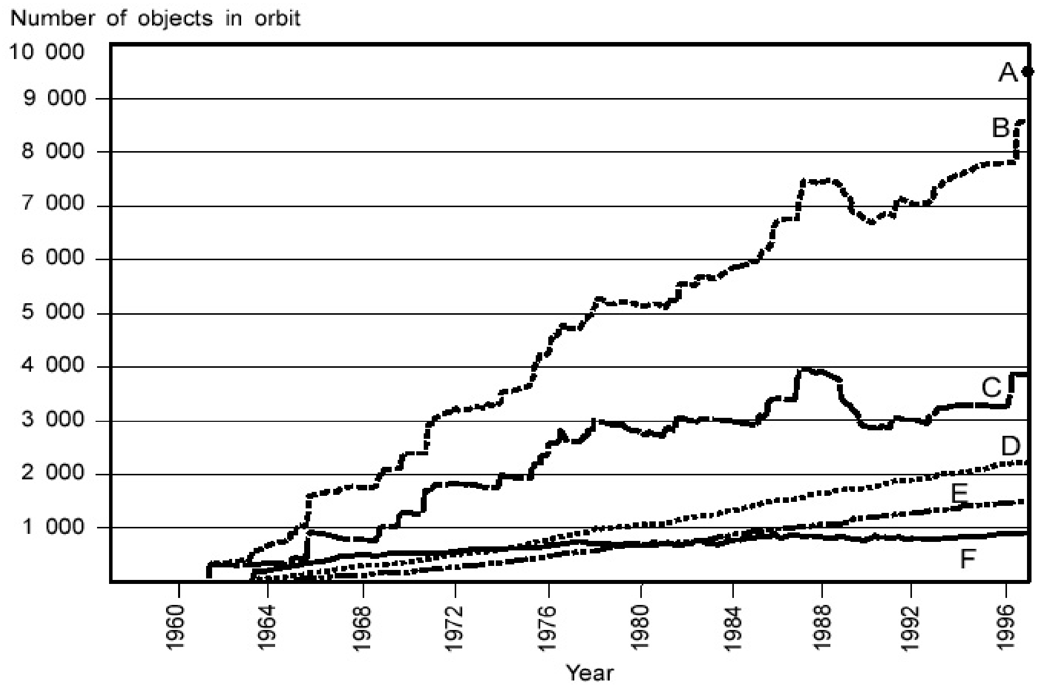
DISCOS includes the location and number of current orbital objects; a historical record of debris in orbit; data that can be used to model the behavior of orbiting objects; and data through which future launch and operational activity can be predicted. (United Nations, 2005)

According to the European Space Agency, in 2003 there were approximately 10,000 catalogued debris objects orbiting the Earth, while there is no good estimate for exactly how many uncatalogued objects exist. The 10,000 catalogued objects were categorized into the following five types with the distribution of each as noted

- Operational spacecraft – 7 percent,
- Mission-related objects – 13 percent,
- Rocket bodies – 17 percent,
- Old spacecraft – 22 percent,
- Miscellaneous fragments – 41 percent.

Exhibit L-3 shows the total number of objects in orbit by year and type of object.

Exhibit L-3. Number of Objects in Orbit by Year and Type of Object



A: Total number of objects, including objects not contained in the official catalogue
B: Total number of objects, based on the official catalogue
C: Fragmentation debris; fragments are counted since the year of event; fragmentation parents are counted as intacts until the date of event; since the event date the parents are counted as fragments
D: Spacecraft
E: Rocket bodies
F: Operational debris; operational debris related to a launch are counted since the year of launch; Salyut 4, 5, 6, 7 and Mir operational debris are not counted since the date of launch of the parent but since a more realistic date

Note: This figure does not take into account objects that have re-entered the atmosphere.

Source: United Nations, 2005

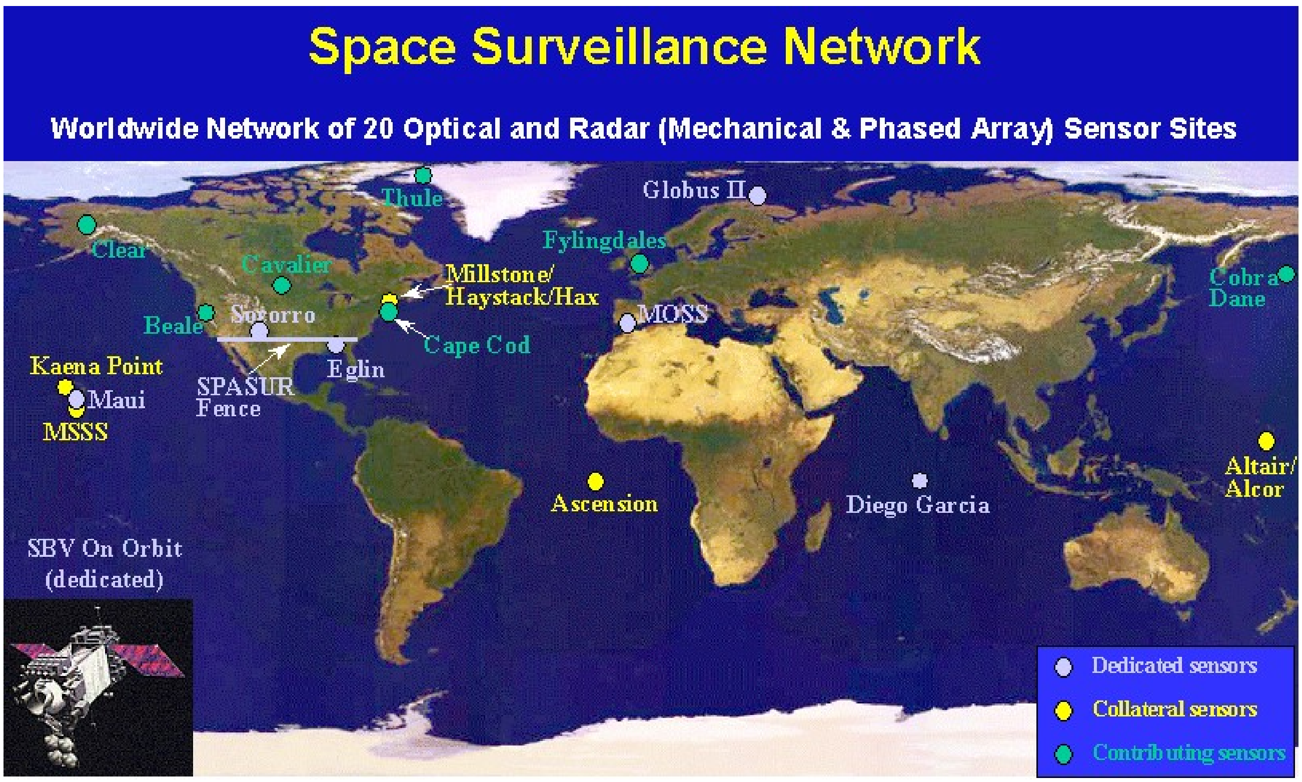
USSTRATCOM uses its SSN to accomplish space surveillance tasks. This involves detecting, tracking, identifying, and cataloging man-made objects orbiting the Earth, including active and inactive satellites, spent rocket bodies, or fragmentation debris. The functions of USSTRATCOM include

- Predicting when and where a decaying space object will re-enter the Earth's atmosphere,
- Charting the present position of space objects and predicting their paths,
- Detecting new man-made objects in space,

- Producing a catalogue of man-made objects in space,
- Determining which country owns a reentering object, and
- Informing NASA if any object might interfere with the space shuttle or the ISS.

The SSN is comprised of ground-based radars and optical sensors at 25 sites operated by the U.S. Army, Navy, or Air Force. Exhibit L-4 depicts the locations of 20 of these sensor sites. Since its beginning in 1957, SSN has tracked 24,500 space objects and currently tracks 8,000 orbiting objects. While its primary concern is operational satellites, USSTRATCOM tracks all space objects greater than 10 centimeters (4 inches) in diameter, including space debris. (U.S. Space Command, 2005)

Exhibit L-4. USSTRATCOM Space Surveillance Network



Source: U.S. Space Command, 2005

USSTRATCOM estimates that of the space objects it tracks, 7 percent are operational satellites, 15 percent are rocket bodies, and 78 percent are inactive or fragmented satellites. (U.S. Space Command, 2005) Therefore, commercial and government satellites are by far the largest contribution to not only space objects but to space debris as well.

L.3 Standards and Policy for Managing Orbital Debris

This section discusses various Federal standards and guidelines for managing and minimizing the risk from orbital debris. This includes the National Space Policy, White House Office of Science and Technology Policy (OSTP), 2006; DoD Directive 3100.10; NASA Safety Standard 1740.14; and the AFSPC policy directive *UPD10-39*.

L.3.1 National Space Policy (OSTP, 2006)

The National Space Policy was issued by the White House Office of Science and Technology Policy in 2006 and addresses specific space guidelines for civil space, commercial space, and national security. In order to support major U.S. space policy objectives, the policy identifies priority intersector guidance related to the defense, international, civil, and commercial space sectors. Among this intersector guidance, issues concerning space debris minimization are addressed. The policy states that NASA, the intelligence community, and DoD, in cooperation with the private sector, will develop design guidelines for future Government procurements of spacecraft, launch vehicles, and services. The design and operation of space tests, experiments, and systems will minimize or reduce accumulation of space debris consistent with mission requirements and cost-effectiveness.

Because it is in the interest of the U.S. Government to ensure that space debris minimization practices are applied by other space faring nations and international organizations, the policy states that the U.S. Government will take a leadership role in international forums to adopt policies and practices aimed at debris minimization. In addition, the U.S. Government will cooperate internationally in the exchange of information on debris research and the identification of debris mitigation options.

L.3.2 Department of Defense Directive 3100.10

The DoD Directive 3100.10 issued in July of 1999 is an update of the DoD Space Policy. It incorporates new policies and guidance disseminated since the last DoD Space Policy update in 1987. It assigns responsibilities and establishes a comprehensive policy framework for the conduct of space and space-related activities. This framework is meant to help articulate the need for capabilities, guide the allocation of resources, and direct program activities.

Among the operational guidance provided, the directive echoes the White House's 1996 National Space Policy regarding the minimization of space debris created. It states that the design and operation of space tests, experiments, and systems shall strive to minimize or reduce the accumulation of such debris consistent with mission requirements and cost effectiveness.

The directive also addresses policy regarding spacecraft end-of-life. It states that spacecraft disposal at the end of mission life shall be planned for programs involving on-orbit operations. Spacecraft disposal shall be accomplished by atmospheric reentry, direct retrieval, or maneuver to a storage orbit to minimize or reduce the impact on future space operations.

L.3.3 NASA Standard

NASA's Safety Standard 1740.14, *Safety Standard Guidelines and Assessment Procedures for Limiting Orbital Debris*, is a set of guidelines addressing how to dispose of spacecraft and structures that will eventually become orbital debris. The standard is divided into three different categories according to the altitude of the spacecraft or structure. These categories apply to structures at altitudes below 2,000 kilometers (1,243 miles), above 2,000 kilometers (1,243 miles), and those that are in near-circular 12-hour orbits. (NASA, 1995)

Spacecraft or structures with perigee altitude (the point at which the structure is closest to the Earth) below 2,000 kilometers (1,243 miles) in its final mission orbit will be disposed of by one of three methods. These are considered the methods of disposal for final mission orbits passing through LEO.

- ***Atmospheric reentry option*** - The structure is left in an orbit. Using conservative projections for solar activity, the structure will last no longer than 25 years after completion of mission. This is due to atmospheric drag. If drag enhancement devices are used to reduce the orbit lifetime, it must be demonstrated that such devices will significantly reduce the area-time product of the system or will not cause spacecraft or large debris to fragment if a collision occurs while the system is decaying from orbit.

- ***Maneuvering to a storage orbit between LEO and GEO*** - The structure can maneuver to an orbit with a perigee altitude above 2,500 kilometers (1,554 miles) and an apogee (the point at which the structure is furthest from Earth) altitude below 35,288 kilometers (21, 928 miles) (500 kilometers [311 miles] below GEO altitude). (Antonio, 2005)

- ***Direct retrieval*** - The structure is retrieved and removed from orbit within 10 years after completion of the mission.

Spacecraft or structures with perigee altitude above 2,000 kilometers (1,243 miles) in their final mission orbits will be disposed of by one of two methods. These are considered the methods of disposal for final mission orbits with perigee altitudes above LEO.

- ***Maneuvering to a storage orbit above GEO altitude*** - Maneuver to an orbit with a perigee altitude above the GEO altitude by a specific distance, which must be calculated according to a formula. A program will use the post-mission disposal strategy that has the least risk of leaving the vehicle near GEO in the event of a failure during the disposal process. Because of fuel gauging uncertainties near the end of mission, it is suggested that the maneuver be performed in a series of at least four burns, which alternately raise apogee and then perigee.

- ***Maneuvering to a storage orbit between LEO and GEO*** - Maneuver to an orbit with perigee altitude above 2,500 kilometers (1,554 miles) and apogee altitude below 35,288 kilometers (21,928 miles) (500 kilometers [311 miles] below GEO altitude).

Final mission orbits with perigee altitudes above 19,900 kilometers (12,366 miles) and apogee altitudes below 20,500 kilometers (12,739 miles), as well as final mission orbits that are (300 kilometers [186 miles] near-circular 12-hour orbits are disposed of using another method. For such orbits, the spacecraft or structure should be maneuvered to an orbit with perigee altitude above 2,500 kilometers (1,554 miles) and apogee altitude below 19,900 kilometers 12,366 miles) or to an orbit with perigee altitude above 20,500 kilometers (12,739 miles) and apogee altitude below 35,288 kilometers (21,928 miles). This would result in placing the spacecraft or structure approximately 500 kilometers [311 miles] below or above GEO altitude.

L.3.4 USSTRATCOM Policy Directive

USSTRATCOM is a unified command under the DoD that oversees the Army, Navy and Air Force Space Commands. In 2001, the U.S. Space Command (USSPACECOM) (now part of USSTRATCOM) prepared a policy directive that applies to all branches. According to this policy directive, *Satellite Disposal Procedures (UPD10-39)*, satellites should be disposed of by one of the following five methods. (U.S. Space Command, 2001)

- ***Atmospheric Reentry*** - This method requires maneuvering the satellite to an orbit in which atmospheric drag will cause atmospheric reentry within 25 years of mission completion. If atmospheric reentry is performed by a planned deorbit, it should be planned such that any remaining portions of the satellite will impact the Earth only in non-populated, preferably oceanic areas.

- ***Between LEO and MEO*** - This method requires maneuvering the satellite to an orbit with a perigee altitude above 2,000 kilometers and an apogee altitude below 19,700 kilometers.

- ***Between MEO and GEO*** **-** This method requires maneuvering the satellite to an orbit with a perigee altitude above 20,700 kilometers and an apogee altitude below 35,300 kilometers.

- ***Above GEO*** **-** This method requires maneuvering the satellite to remove it from Earth orbit into a heliocentric orbit.

- ***Direct Retrieval*** **-** This method requires retrieving the satellite and removing it from orbit as soon as is practical after mission completion.

L.4 MDA Activities and Orbital Debris Risk

This section describes the MDA flight test activities that have resulted in or may result in the generation of orbital debris. It discusses how MDA analyzes its activities to identify, assess and mitigate risk, and also describes MDA's participation in on-going governmental debris risk assessment activities.

L.4.1 MDA Activities

Successful flight tests of the BMDS in the exoatmosphere would result in kinetic energy (i.e., hit-to-kill) intercepts that would produce both target and interceptor debris clouds. With the need for increasingly realistic test scenarios, MDA is considering high altitude, high velocity intercept tests. MDA analysis of BMDS flight tests employing ground-launched interceptors shows that the majority (90 to 95 percent) of post-intercept debris reenters the Earth's atmosphere within six hours. A small amount of post-intercept debris may become orbital debris; however, modeling indicates that risk to spacecraft from intercept debris is far lower than the risk posed by existing background debris. Additional efforts are on-going to determine flight test risks in the space environment and resulting potential impacts on orbiting spacecraft.

L.4.2 MDA Risk Analysis

Prior to every BMDS flight test, MDA assesses the risks posed to spacecraft from the post-intercept debris. Launch times are selected to preclude any conjunctions between spacecraft and intercept debris. If necessary, additional analysis is conducted to determine safe launch times within windows thereby minimizing the risks to spacecraft. This analysis allows MDA to determine when to safely conduct a flight test.

A typical BMDS flight test planning process starts approximately 18 to 24 months prior to the mission launch date. The intercept debris risk assessment addresses both surface and space risk areas. Using an intercept debris model designed and verified and validated for hit-to-kill intercepts, the target and interceptor debris clouds are calculated. This model considers the mass properties and engagement conditions (e.g., altitude, velocity, flight path angle). The debris clouds are propagated forward in time and conjunctions

between spacecraft and the intercept debris are identified. Launch times are selected when no conjunctions occur. At times, additional analysis is conducted to determine the probability of impact between spacecraft and intercept debris. This analysis is very thorough and complete. It considers the time and spatial dependence of the intercept debris density, satellite dwell time within the intercept debris field, and satellite area. Once again, launch times are selected when the risk level is low. The MDA works with Air Force Space Command and NASA to make sure all spacecraft are considered including manned spacecraft.

This analysis is performed throughout the entire mission planning process up to the day and hour of launch. It is refined continuously as the mission date nears. Early analyses assist in determining the mission feasibility and aid in mission planning and execution.

It is important to note that both surface and space risk analyses are conducted initially to determine a scenario's feasibility before it is deemed acceptable and the mission planning process starts. If the risks are considered too high (both surface and space), the scenario is redesigned before mission planning ever begins.

L.4.3 MDA Coordination

MDA is participating in the development of an inter-Agency workgroup to ensure that BMDS flight tests are conducted in a manner that permits a thorough and realistic testing of the BMDS while minimizing risk to manned and unmanned spacecraft per the National Space Policy, OSTP, 2006 as implemented by DoD Directive 3100.10. MDA is currently working with NASA, AFSPC, USSTRATCOM, and several other government agencies to establish a safe means to conduct more operationally representative flight tests.

These efforts build upon the current analytic process and inter-Agency coordination procedures as mentioned above. Risks would be assessed for launch window screening to minimize the risk to both manned and unmanned spacecraft with the goal of developing criteria for protecting space assets.

APPENDIX M
PERCHLORATE TECHNICAL APPENDIX

Foreword

This appendix is not intended to be a stand-alone document or create DoD or MDA policy with respect to perchlorate-related issues. This technical appendix was prepared in response to public comments received on the BMDS PEIS.

This appendix

- Provides an overview of the uses, manufacturing, and disposal of perchlorate for both general commercial purposes and specific MDA or DoD uses;
- Presents DoD's significant contributions to perchlorate detection technology and ongoing research into potential health effects, viable alternatives and treatment methods; and
- Describes health effects and ecological impacts of perchlorate, and the development of an RfD and guidance levels for perchlorate.

This appendix is necessary to support MDA analysis of the potential environmental impacts of BMDS proposed activities, which includes the use of perchlorate as an oxidizer in rocket motors, and to respond to public comments regarding perchlorate that MDA received on the Draft BMDS PEIS.

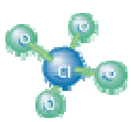
Specifically, public commenters requested that the PEIS

- Address health impacts on susceptible populations including fetuses and children;
- Factor an inhalation pathway for exposure to ammonium perchlorate, including assessments for both public and occupational exposure;
- Present the findings used to support the development of the proposed state guidance levels for perchlorate rather than relying on the findings of the Perchlorate Study Group;
- Include the findings of the NRC of the National Academy of Sciences (NAS) report;
- Include detailed estimates of perchlorate waste likely to be generated by system development, testing, deployment, and decommissioning; and
- Include site-specific analyses of the impacts of perchlorate debris on any freshwater lake or confined ocean areas that might receive perchlorate debris.

PERCHLORATE TECHNICAL APPENDIX

M.1 Introduction

Perchlorate is a common component in a number of commercial industry and government applications. The most common use is as an oxidizer in rocket motors, explosives, and pyrotechnics. Historical disposal practices resulted in the release of perchlorate to the environment. Contemporary concern about perchlorate stems from improved detection capabilities that revealed varying concentrations in ground water. Several human systems, especially the thyroid, have been shown to be sensitive to perchlorate. Historically, perchlorate was once used to treat thyroid disorders in people with a thyroid condition called Graves' disease. This appendix provides a review of the uses, manufacturing, and disposal of perchlorate for both general commercial purposes and specific MDA or DoD uses. It presents DoD's significant contributions to perchlorate detection technology and ongoing research into potential health effects, viable alternatives and treatment methods. Additionally, the appendix describes health effects and ecological impacts of perchlorate, and the development of guidance levels for perchlorate.



Perchlorate (ClO_4^-) is an anion, or negatively charged ion, that originates from both natural and man-made sources. The basic chemical composition of perchlorate consists of an atom of chlorine surrounded by four atoms of oxygen. Perchlorate is manufactured and used as a solid salt compound that typically contains ammonium, potassium, magnesium, or sodium. For this reason, the terms perchlorate and perchlorate salts are used interchangeably and are inclusive of all forms of perchlorate compounds.

Perchlorate is of interest to this analysis because of public concerns over the compound's presence in the natural environment and its potential effects on human health. In 1998, the U.S. Environmental Protection Agency (U.S. EPA) added perchlorate to the contaminant candidate list, which is U.S. EPA's priority list of drinking water contaminants. Contaminants on this list may require regulation and may undergo additional research and data collection before U.S. EPA can determine whether or not a regulation is appropriate. Although U.S. EPA has not determined whether a drinking water standard is appropriate, ground water contamination from the manufacture and disposal of perchlorate-containing chemicals is controversial and of increasing concern to ensure the safety and quality of the nation's water supply. The detection of perchlorate in drinking water systems is attributable to improvements in detection technology capable of measuring levels of perchlorate found in the environment. Technologies that use ion chromatography with preconcentrators or liquid chromatography with mass spectrometry can now detect perchlorate to sub ppb levels. One ppb is equivalent to a single kernel of

corn in a silo measuring 16 feet in diameter and 45 feet high full of corn. See Exhibit M-1 for a comparison of existing perchlorate analytical laboratory methods.

Exhibit M-1. Perchlorate Analytical Laboratory Methods Comparison

Method	Description	Target Reporting Limit	Source
Current U.S. EPA Methods			
Method 314.0	Uses an ion chromatography instrument that includes an anion separator column, an anion suppressor device, and a conductivity detector. Includes alternatives for cleanup (pretreatment) procedures to cope with interfering ions.	0.1 µg/L is target reporting limit for perchlorate in drinking water	U.S. EPA. 1999. "Method 314.0. Determination of Perchlorate in Drinking Water using Ion Chromatography." Revision 1.0. National Exposure Research Laboratory, Office of Research and Development. November.
Method 9058	Uses an ion chromatography instrument that includes an anion separator column, an anion suppressor device, and a conductivity detector.	4 µg/L is Limit of Quantitation (LOQ). Method detection limit is 0.7 µg/L in ground water.	U.S. EPA. 2000. "Method 9058. Determination of Perchlorate using Ion Chromatography with Chemical Suppression Conductivity Detection." Revision 0. SW-846 Update IVB. November.
Method 314.1	Uses a preconcentrator to remove common interferents, including chloride, carbonate, and sulfate. In addition, provides for use of a second column to confirm identity of perchlorate.	0.5 – 1 µg/L	U.S. EPA. 2005e. "Determination of Perchlorate in Drinking Water Using Inline Column Concentration/Matrix Elimination Ion Chromatography with Suppressed Conductivity Detection." Document number 815-R-05-009. Revision 1.0. May. http://www.epa.gov/safewater/methods/pdfs/method_314_1.pdf.
Method 331.0 – "Determination of Perchlorate in Drinking Water by Liquid Chromatography Electrospray Ionization Mass Spectrometry"	Uses a different chromatographic method to separate perchlorate from other ions, which may be more effective in reducing interference. Tandem mass spectrometry provides a tool to eliminate sulfate interference. The method quantitates perchlorate against an isotopically labeled (oxygen-18) internal standard. This method may provide versatility needed for difficult matrices.	0.02 µg/L	U.S. EPA. 2005f. "Determination of Perchlorate in Drinking Water by Liquid Chromatography Electrospray Ionization Mass Spectrometry." Document number. Revision 1.0. Document number 815-R-05-007. January. http://www.epa.gov/safewater/methods/met331_0.pdf Accessed January 2006.
Method 332.0 – "Determination of Perchlorate in Drinking Water Using Ion Chromatography with Suppressed Conductivity	Substitutes an electrospray ionization mass spectrometry (ESIMS) detector for the conductivity detector of Method 314.0. Provides confirmation of identity of perchlorate or definite evidence of false positive results from interferents. Can handle relatively high	0.1 µg/L Ion Chromatography/Mass Spectrometry (IC/MS) and 0.02 µg/L (IC/MSMS)	U.S. EPA. 2005g. "Determination of Perchlorate in Drinking Water Using Ion Chromatography with Suppressed Conductivity and Mass Spectrometric Detection." Revision 1.0. Document number EPA/600/R-05/049. March. http://www.epa.gov/nerlcwww/m_332_0.pdf, accessed January 2006.

Method	Description	Target Reporting Limit	Source
and Mass Spectrometric Detection”	concentrations of total dissolved solids.		
Methods Under Development			
Method 6850 – “Determination of Perchlorate Using High Performance Liquid Chromatography/ Mass Spectrometry”	Uses the technology of Method 331.0 to separate perchlorate from other ions and the technology of Method 332.0 to confirm the identity of perchlorate and quantitate it.	Practical quantitation limits (PQL) are 0.2 µg/L for water (drinking water, simulated ground water, and Great Salt Lake water), 2 µg/L for soil, and 6 µg/L for biota (grass). Method detection limits are about 1/3 of the PQLs.	U.S. EPA. 2004b. E-mail message regarding perchlorate analysis. From Mike Carter, (EPA Federal Facilities Restoration and Reuse Office) to John Quander. July 14.
“Rapid Determination of Perchlorate Anion in Foods by Ion Chromatography – Tandem Mass Spectrometry”	Developed in support of an ongoing program for collection and analysis of foods to measure perchlorate content. Samples are extracted by food-specific methods. Extracts are then separated by ion chromatography as in Method 332.0 and determined by the technology (including the internal standard) used in Method 331.0.	LOQs are 0.5 µg/L for drinking water, 1 µg/L for fruits and vegetables, and 3 µg/L for milk	FDA. 2004. “Draft Rapid Determination of Perchlorate Anion in Lettuce, Milk, and in Bottled Water by HPLC/MS/MS.” Revision 0. Dated March 17. Downloaded July 15 from http://www.cfsan.fda.gov/~dms/clo4meth.html.
Field Screening Method for Perchlorate in Water and Soil	A field screening colorimetric method for perchlorate was developed by the U.S. Army Corps of Engineers (USACE). This method was published as a report (ERDC/CRREL TR-04-8), which is available for download at http://www.crrel.usace.army.mil/techpub/CRREL_Reports/reports/TR04-8.pdf.	Detection limits: 1 µg/L for water; 0.3 µg/g for soil	USACE. 2004. Field Screening Method for Perchlorate in Water and Soil. U.S. Army Engineer Research and Development Center (ERDC)/Cold Regions Research and Engineering Laboratory (CRREL) TR-04-8. April.

Source: Environmental Protection Agency, Office of Solid Waste and Emergency Response (OSWER): Perchlorate Treatment Technology May 2005 (EPA 542-R-05-015) http://www.clu-in.org/download/remed/542-r-05-015.pdf

While perchlorate has been detected in the drinking water of 35 states plus Puerto Rico and the Mariana Islands, the apparent absence of perchlorate in other regions may be due to the small number of sampled areas. (U.S. EPA, 2005d)

The U.S. EPA is responsible for establishing Federal drinking water standards where this is considered appropriate. Several Federal agencies initiated collaborative research efforts to better understand the fate, effects, and potential remediation strategies for perchlorate in the environment. This effort was initially coordinated by the Interagency

Perchlorate Steering Committee (IPSC), followed in 2002 by the establishment of the Perchlorate Interagency Working Group (IWG). The IWG is coordinated by the Office of Management and Budget and the Office of Science and Technology Policy and includes several agencies – White House CEQ, U.S. EPA, DoD, NASA, Department of Health and Human Services, and Department of the Interior.

Because of data limitations and controversies regarding the interpretation of the research results on perchlorate in U.S. EPA's draft perchlorate risk assessments, the IWG asked the NRC of the NAS to independently assess the state of the science regarding potential thyroid disruption, levels of chronic inhibition of iodine uptake that lead to adverse effects, and levels at which changes in thyroid hormones lead to adverse effects. The NRC was also tasked to review the scientific literature and findings from the U.S. EPA's 2002 draft risk assessment, *Perchlorate Environmental Contamination: Toxicological Review and Risk Characterization*.

The NRC study recommended an RfD of perchlorate of 0.0007 mg/kg per day.[1] The NRC stated that this value is supported by clinical studies, epidemiologic studies, and studies of long-term perchlorate administration. The NRC report concluded that the proposed RfD of 0.0007 mg/kg per day should protect even the most sensitive populations. The U.S. EPA established a reference dose of 0.0007 mg/kg per day of perchlorate in its Integrated Risk Management System based on the NRC report. Doses below the RfD are considered safe. Doses exceeding the RfD will not necessarily lead to adverse effects as there are uncertainties incorporated into the calculation of the RfD. The possibility that adverse effects might occur increases the higher the dose is above the RfD.

M.2 Use and Manufacturing

Commercial industry and government entities use perchlorate for many applications. Perchlorate currently is used in approximately 250 types of munitions (approximately 14 percent) used by DoD today. The most common application is as an oxidizer in rocket motors, explosives, and pyrotechnics. Section M.3 discusses other industrial uses of perchlorate. It is estimated that 92 percent of perchlorate is sold for end-use as an oxidizer in solid rocket fuel, 7 percent as an explosive, and 1 percent for other uses. (Crowley, 2004) Oxidizers are the compounds that release oxygen to support a combustion reaction. The high ignition temperature, controllable burn rate, and stable chemical characteristics of perchlorate make it one of the most efficient and reliable materials currently available for use as an oxidizer. (DoD, 2005a)

---

[1]The RfD is an estimate (with uncertainty spanning perhaps an order of magnitude) of a daily oral exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime. It can be derived from a no observed adverse effect level (NOAEL), lowest observed adverse effect level (LOAEL), or benchmark dose, with uncertainty factors generally applied to reflect limitations of the data used.

All military services (Air Force, Army, and Navy) use munitions, ordnance, etc. that contain perchlorate at the following types of facilities: ammunition plants, research laboratories, depots, proving grounds, testing facilities, rocket maintenance facilities, and training bases. (DoD, 2005a)

The principal ingredient in solid rocket propellant is ammonium perchlorate (a perchlorate salt), making the DoD and NASA the largest users of this type of perchlorate in the U.S. (DoD, 2005b; Aerospace Corporation, 2002) In fact, more ammonium perchlorate is used for solid rocket fuel production than for all other perchlorate uses combined. (AWWA, 2005) The GBI, Standard Missile-3, THAAD missile, PAC-3 missile, and the KEI under development are MDA missiles that use solid propellants containing perchlorate.

Of the four perchlorate salts listed in Exhibit M-2, ammonium perchlorate is the most commonly used. Although the four perchlorate salts have similar effects once introduced into the environment, they have distinctly different uses as outlined in Exhibit M-2.

Exhibit M-2. Military and Commercial Uses of Perchlorate Salts

Type of Perchlorate	Uses
Ammonium (NH_4ClO_4)	Solid rocket fuel oxidizer, flares, explosives, pyrotechnics, and chemical processes
Potassium ($KClO_4$)	Solid rocket fuel oxidizer, flares, air bag inflation systems, pyrotechnics such as fireworks, training simulators, hand grenade delays, aircraft countermeasures, and detection of defects in thyroid function (medical use)
Magnesium ($Mg(ClO_4)_2$)	Military batteries
Sodium ($NaClO_4$)	Slurry explosives, electro-machining, and chemical processes (precursor to potassium and ammonium perchlorate)

Source: American Pacific Corporation, 2005; California EPA, 2004; DoD, 2005; NRC, 2005; Greer et al., 2002; U.S. EPA, 2002

In the U.S., two companies began full-scale commercial production of perchlorate-containing chemicals in the 1940s, with combined production volumes ranging from 1 to 15 million pounds per year. (U.S. EPA, 2002) Production peaked in the 1980s with volumes of 20 to 30 million pounds per year. (U.S. EPA, 2002) Annual production volumes have been decreasing from 16.4 million pounds of Grade I ammonium perchlorate in 2002 to between 10 million and 11 million pounds in 2004. (Crowley, 2004) In 2003, NASA's Space Shuttle program used a little more than half of the ammonium perchlorate produced and DoD (including MDA) used the majority of the remaining ammonium perchlorate produced that year.

M.3 Other Sources of Perchlorate

Although military uses account for much of the perchlorate produced and used, other sources exist including those derived from

- Storage, handling, and use of Chilean nitrate-based fertilizers containing perchlorate;
- Manufacturing, storage, handling, use, and/or disposal of fireworks containing perchlorate;
- Manufacturing, storage, handling, use, and/or disposal of road flares containing perchlorate;
- Manufacturing, storage, handling, use, and/or disposal of explosives or pyrotechnics containing perchlorate; and
- Manufacturing, storage, handling, and use of electrochemically-prepared chlorine products (primarily those that contain chlorate or were manufactured from chlorate feedstocks). (SERDP, 2005)

Chilean Nitrate Fertilizer: Records show that between 1909 and 1929, the U.S. imported an estimated 19 million tons of Chilean nitrate (Goldenwieser, 1919 and Howard, 1931, as cited in SERDP, 2005), 65 percent of which was used as fertilizer. (Brand, 1930, as cited in SERPD, 2005) U.S. EPA research found an average perchlorate content in Chilean nitrate of about 0.2 percent. Using this average, approximately 49 million pounds of perchlorate may have been unknowingly applied to agricultural crops during this time. (SERDP, 2005) The use of Chilean nitrate fertilizer has declined but it is still used in limited quantities. (SERDP, 2005) The "Santa Ana Regional Water Quality Board officials have recently acknowledged that a major source of perchlorate pollution in some Southern California drinking water supplies may be the Chilean nitrate fertilizer that was applied to the region's citrus crops for decades into the early 20th century. (Press Enterprise Company, 2004)

Fireworks: In 2003, 221 million pounds of fireworks were consumed in the U.S. (SERDP, 2005) Perchlorate is used as an oxidizer in fireworks; however, there is little information related to the amount of perchlorate residue remaining after burning fireworks or on the number of dud fireworks used. Therefore, it is difficult to estimate potential perchlorate inputs from fireworks to the environment. Recent studies have detected perchlorate in soils, ground water and/or surface water following fireworks displays. (SERDP, 2005)

Safety Flares: Preliminary research indicates that 3.6 grams of perchlorate can potentially leach from an unburned, damaged (e.g., run over by a motor vehicle) 20-minute road flare. It has been estimated that some 20 to 40 million flares may be sold annually. Given this estimate, up to 237,600 pounds of perchlorate could leach from road flares annually. (SERDP, 2005) Studies have shown that one unburned flare can leach up to 243,000 ppb of perchlorate when in contact with 15 liters of water for 3.5 hours. This

could be enough to contaminate up to 2.2 acre-feet of water to 4 ppb. Under similar conditions, even completely burnt flares released perchlorate at rates up to 130 ppb per flare. (DoD, 2005b)

Blasting Explosives: Some explosives can contain substantial amounts of perchlorate (e.g., up to 30% by weight). Most of the perchlorate would be consumed during the detonation; however, spills, improper use, or misfires could potentially result in contamination of surface and ground water. (SERDP, 2005)

Chlorine Chemicals: During the electrochemical manufacture of chlorine products, such as chlorate, perchlorate may be formed as an impurity at concentrations of 50 to 500 mg/kg. The North American annual chlorate manufacturing capacity is estimated at 2.4 million tons, and the total annual consumption of sodium chlorate in the U.S. is approximately 1.2 million tons. (SERDP, 2005) The pulp and paper industry uses approximately 94% of all sodium chlorate consumed in the U.S. and effluents from pulp mills have been reported to contain chlorate (1 to 70 milligrams per liter). (SERDP, 2005) However, there is little information about the potential for perchlorate release from these facilities. Sodium chlorate is also used as an herbicide and defoliant for cotton, sunflowers, sundangrass, safflower, rice, and chili peppers. (SERDP, 2005)

Natural Sources: Tests conducted by Texas Tech University suggest that there is a natural flux of atmospheric perchlorate to the Earth as well as a natural perchlorate level. (Environmental Science and Technology Online News, 2005) With improved detection methods researchers have found low levels of perchlorate in many locations. The Texas Tech study found highly variable data ranging from levels too low to detect to levels measuring in the ppb. (Environmental Science and Technology Online News, 2005) The specific reasons for this variability were not determined and follow on studies have been proposed.

Exhibit M-3 shows the current and historical uses of perchlorate.

Exhibit M-3. Current and Historical Uses of Perchlorate

Raw Product	Product/Process	Role of Perchlorate in the Product/Process
Perchlorate Salts	Ammonia production	Ingredient of catalytic mixtures used in making ammonia
	Detonating compositions	Oxidizing Agent
	Matches	Oxidizing Agent
	Pyrotechnic compositions	Oxidizing Agent
	Railroad signal (fuse) compositions	Oxidizing Agent
	Smoke-producing compounds	Oxidizing Agent
	Metallurgical	Constituent of brazing fluxes, welding fluxes
	Pharmaceutical	Used in compounding and dispensing practice
	Air bags for vehicles	Initiators
	Paints and enamels	Curing/Drying Agent
	Photography	Flash powder/ oxidizing agent
	Oxygen generators	Burn Rate Modifier
	Road flares	Oxidizing Agent
	Ejection seats	Propellant
	Model rocket engines	Propellant
	Rockets used for research, satellite launches, and Space Shuttle	Propellant
	Some explosives in construction, mining and other uses	Oxidizing Agent
	Fireworks	Oxidizing Agent
	Voltaic cells and batteries involving lithium or lithiated anodes, non-aqueous solvents or polymeric films, and manganese dioxide or other transition metal oxides	Electrolyte (Lithium perchlorate)
	Zinc and magnesium batteries	Electrolytes (Zinc perchlorate and magnesium perchlorate)
	Electropolymerization reactions involving monomers such as aniline, benzidine, biphenyl, divinylbenzene, and indole	Electrolyte
	Polyvinyl chloride	Dopants to improve heat stability and fire retardation characteristics
	Thin film polymers such as polyethylene oxide, polyethylene glycol, or poly (vinylpyridine)	Dopant to impart conductive properties in various electrochemical devices
	Drying agent for industrial gases and other similar applications	Desiccant (Anhydrous magnesium perchlorate)
	Plastics and polymers	Dopants to impart antistatic and conductive properties
Perchloric Acid	Nitrogen measurement	Used for Kjeldahl digestions
	Leather tanning	Extraction of chromium

Raw Product	Product/Process	Role of Perchlorate in the Product/Process
	Potash measurement	Used to form insoluble potassium perchlorate
	Manufacture of inorganic chemicals, intermediates, organic chemicals, pharmaceuticals, synthetic aromatics	Oxidizing Agent
	Manufacture of explosive compounds, such as the perchlorated esters of monochlorohydrin.	Reagent
	Ingredient of lead-plating baths	Facilitates the deposition of lead from baths containing lead perchlorate
	Electropolishing operations	Electrolyte in anodization of metals to produce non-corroding surfaces
	Metallurgy	Extraction of rare earth metals
	Etching brass and copper	Acid
	Acetylations, alkylations, chlorinations, polymerizations, esterifications, and hydrolyses	Catalyst
	Cellulose acetate production	Esterification of cellulose
	Destruction of organic matter, especially in preparation for the determination of calcium, arsenic, iron, copper, and other metals	Acid digestion, in combination with nitric acid
	Determination of copper and other metals in sulfide ores	Acid digestion
	Dissolving refractory substances such as titanium slags	Acid digestion
	Ammonium perchlorate, high purity metal perchlorates	Starting material for the manufacture of pure ammonium perchlorate and in the production of high purity metal perchlorates
	Pickling and passivation of iron and steels	Oxidant
	Determination of silica in iron and steel and in cement and other silicate materials	Dehydrating Agent
	Determination of chromium in steel, ferrochrome, chromite, leather, and chromatized catgut	Oxidizing Agent
	Separation of chromium from other metals by distillation of chromyl chloride	Used in combination with hydrochloric acid
	As a primary standard acid	Perchloric acid, when distilled in a vacuum at a carefully regulated pressure, has exactly the composition of the dihydrate, 73.6% $HClO_4$
	Indirectly in the manufacture of anhydrous magnesium perchlorate	Dehydrating Agent

Raw Product	Product/Process	Role of Perchlorate in the Product/Process
	Titration of bases in non-aqueous solvents	As the strongest of the strong acids dissolved in anhydrous acetic acid
	Analytical procedures for the destruction of organic matter prior to the determination of metallic and non-metallic ingredients such as: • Determination of sulfur in coal, coke, and oils; • Determination of iron in wine, beer, and whiskey; • Determination of chromium and of iron in leather and tanning liquors; • Determination of phosphorus, alkali metals, lead, and other ingredients; and • Analysis of blood for calcium and of urine for lead.	Destruction of organic matter (mixtures of perchloric acid dihydrate with nitric acid or sulfuric acid, or of these three acids together)
Chilean Sodium Nitrate	Fertilizers	Incidental ingredient in fertilizers (largely historical, but soils previously treated may still contain perchlorate)
	Charcoal briquettes	Naturally occurring by-product
	Meat tenderizers	Naturally occurring by-product

Source: SERDP, 2005

M.4 Disposal

As seen in Exhibit M-3, perchlorate can enter the environment through a variety of sources including: solid rocket propellant, Chilean nitrate fertilizers, fireworks, safety flares, blasting explosives, and electrochemically-prepared chlorine products. However, the discussion on disposal of perchlorate in this appendix focuses on the disposal of perchlorate generated by DoD activities.

Perchlorate is most commonly used in solid rocket propellant. Solid rocket propellant has a finite shelf life and periodically must be replaced. Consequently, a large amount of ammonium perchlorate has been disposed of since the 1950s. For example, the SRM fuel used in the GBIs has a planned shelf life of approximately 20 years. However, the solid rocket fuel contained in the Minuteman missiles has remained viable for 32 years. The specific chemical composition of the SRM propellant and the environmental conditions (temperature and humidity) of the storage area influence the shelf life of the SRM propellant. (California EPA, 2004)

Although the exact amounts of perchlorate disposed of are not available, the number of pounds of SRM requiring disposal has been reported. In 1998, the U.S. had 55 million pounds of SRM propellant requiring disposal. This amount is projected to grow to over 164 million pounds by the end of 2005. (U.S. EPA, 2002) The Minuteman III Propulsion

Replacement Program will remove over 35 million pounds of propellant from 1,200 first and second stage motors to recover and reuse the motor cases. (ESTCP, 2000)

Most of the perchlorate that has been found in ground water is due to past disposal practices that are no longer used today. Past disposal methods for solid rocket propellant included open-burning, open-detonation, or static (stationary) firing of SRMs as well as dumping off-specification batches of solid propellant. In some isolated past practices, the wastewater was discharged into unlined waste ponds. Many areas where perchlorate has been detected in ground water are located near weapons and rocket fuel manufacturing facilities and disposal sites, research facilities, and military bases. (DoD, 2005a)

The Services have prepared various directives and instructions regarding the responsibility of safely managing munitions and rocket engines. For example, as discussed in OPNAV Instruction 8026.2A, Navy Munitions Disposition Policy (15 June 2000), DoD Directive 5160.65 (Nov 81), "Single Manager for Conventional Ammunition," designated the Secretary of the Army as the Single Manager for Conventional Ammunition (SMCA). The SMCA is assigned responsibility for demilitarization, recycling, declassification and disposal of all munitions (SMCA and non-SMCA managed) except large strategic missile rocket motors. The Director, Strategic Systems Programs (DIRSSP) is responsible for Navy large strategic missile rocket motor demilitarization, reclamation, declassification and disposal.

These directives and instructions prohibit many of the past disposal practices and have established DoD's preferred hierarchy of demilitarization and disposal techniques for minimizing environmental, health and safety impacts.

- Complete reuse or recycling of system components and materials,
- Reprocessing system components and materials into a useful format,
- Sale or donation to the private sector and other governments, and
- Waste disposal (as a final resort).

At MDA and throughout DoD, significant effort is expended in reusing excess or surplus rocket engines by providing them to one of the Services for use as target vehicles or lift vehicles. In fact, a significant portion of the target vehicles acquired by MDA are obtained from the Services. This practice prevents the excess or surplus rocket engine from becoming a waste that would need to be managed.

In cases when a Service cannot use the rocket engine, as is the case in some rocket engine remanufacturing or demilitarization programs, the rocket engine might be destroyed using controlled firings or the rocket popellant washed out of rocket motor casings using high-pressure water or other techniques such as cryogenic removal. Although some of these processes might generate wastewater streams containing dissolved rocket

propellant, they are handled and managed in accordance with appropriate wastewater regulations.

Specifically, non-hazardous wastewaters are handled as industrial wastewaters that are treated in wastewater treatment plants. Wastewaters that might exhibit one of the characteristics of a hazardous waste under the Resource Conservation and Recovery Act (RCRA) are treated and disposed of in a RCRA Subtitle C facility or are discharged via a National Pollution Elimination Discharge System permitted outfall. (ESTCP, 2000) Likewise, solid waste streams are handled in accordance with either the industrial waste (Subtitle D) regulations or the hazardous waste (Subtitle C) regulations to safely manage and prevent the introduction of hazardous constituents into our environment. The waste handling requirements of RCRA ensure the public is protected from the hazards of waste disposal, and that any wastes that may have been spilled, leaked or improperly disposed are cleaned up. (ESTCP, 2000; Motzer, 2003; U.S. EPA, 2004)

M.5 Department of Defense Efforts

The DoD has been a leader in perchlorate-related research. The DoD developed and contributed to establishing technologies that detect perchlorate at extremely low levels. Prior to 1997, the lowest detection level was 400 ppb. Through cooperation with DoD, U.S. EPA approved a method, Method 314.0, that allows detections as low as 1- 4 ppb.[2] The state of California started using a 4 ppb detection limit prior to the approval of U.S. EPA Method 314.0. Following the detection of these lower levels, DoD and other Federal and state authorities formed the IPSC. The Committee assembled the leading perchlorate specialists to coordinate efforts to better understand the occurrence, health effects, treatability and waste stream handling, analytical detection, and ecological impacts of perchlorate contamination in drinking water and irrigation water supplies. The IPSC aimed to address public concerns about perchlorate and to provide real-time information on the issue. Its collaborative efforts continue under the 2002 IWG that funded the 2005 independent review of the perchlorate issue by the NRC.

In 2000, DoD formed the Perchlorate Workgroup to coordinate internal perchlorate research and technology development. Through the Workgroup, DoD cooperates with Federal, state, and local officials and host communities to effectively address perchlorate concerns at active, base realignment and closure (BRAC) sites, and Formerly Used

---

[2] The original perchlorate detection method, EPA Method 314.0, was based on ion chromatography with a conductivity detector. There have been concerns about the potential for both false positive and false negative identifications as well as this methods ability to reliably detect and quantitate low concentrations. The Office of Water has now published several new perchlorate methods using either ion chromatography or liquid chromatography coupled to a mass spectrometer detector which results in identifications that are extremely reliable. (See Exhibit M-1.) In addition, the Office of Solid Waste is developing analogous mass spectrometer methods applicable to soil, sediment and waste samples that are also very sensitive with measurement capabilities in the parts per trillion range.

Defense Sites. The Workgroup's mission is to provide for further research into the actual extent of perchlorate in ground and surface water, pollution prevention measures, safe and effective alternatives to perchlorate, potential health effects from chronic, low-level perchlorate exposure in drinking water, ecological effects, and suitable treatment technologies. To date, DoD has spent over $59 million on efforts including: investigations into perchlorate sampling and analysis, identifying and evaluating innovative and cost-effective remediation technology, applying pollution prevention principles to minimize and eliminate perchlorate waste streams, and finding alternatives to perchlorate in munitions. MDA continues to follow DoD policy and guidance regarding the sampling and analysis of perchlorate.

The DoD's action plan reflects a commitment to protect public health and the environment by

- Sampling for perchlorate;
- Establishing priorities for sampling and monitoring that reflect the most sensitive exposure pathways;
- Monitoring and determining appropriate actions to prevent migration of perchlorate into drinking water supplies;
- Incorporating Federal or state regulatory standards, whichever are more stringent, into the DoD's clean up program once standards are established for perchlorate; and
- Preventing pollution and investing in finding substitutes for the various military uses of perchlorate that will have less public health and environmental concerns. (SERDP, 2005)

Perchlorate Recycling Efforts

In December 2002, the Army established a missile recycling center at Anniston Army Depot in Alabama. This recycling center enables the Army to safely dispose of obsolete and over-aged tactical missiles in an environmentally responsible manner. The Army estimates that 600,000 outdated missiles at ammunition storage sites and plants across the country and overseas need to be recycled over the next 10 to 15 years. The Army estimates that 98 percent of the missile hardware, warhead explosives and propellant ingredients can be reused or recycled into various industrial or military applications. The current recycling production rate at this facility is approximately 15,000 missiles annually. The Army hopes to be able to recover over 80 million pounds of ammonium perchlorate to be used in new military munitions or converted into various industrial products including potassium perchlorate (used by the air bag industry), perchloric acid, and other specialty chemicals. (DoD, 2005a)

Researching Alternatives to Perchlorate

DoD is currently evaluating alternatives to perchlorate in munitions. For example, the Army is in the process of replacing perchlorate in two training simulators which are responsible for the majority of the perchlorate expended (fired) on Army training ranges today. The M115A2/Ground Burst projectile simulator and the M116A1/Hand Grenade Simulator expend approximately 10.8 tons of perchlorate per year for training. The perchlorate is consumed when the simulators are used; however, concern over the integrity of the cardboard casing in the rain, and the chance of incomplete consumption of the perchlorate led the Army to replace the perchlorate composition as a precautionary measure. The Army expects to have the replacement simulators fielded and operational by 2006. (DoD, 2005a)

Other examples of replacement efforts include potential alternatives for rocket and missile propellants, smoke formulations for rockets, and flares and signals. The DoD carefully weighs safety, cost, and potential for contamination when determining which munitions to target for perchlorate replacement. (DoD, 2005a)

M.6 Human Health Effects

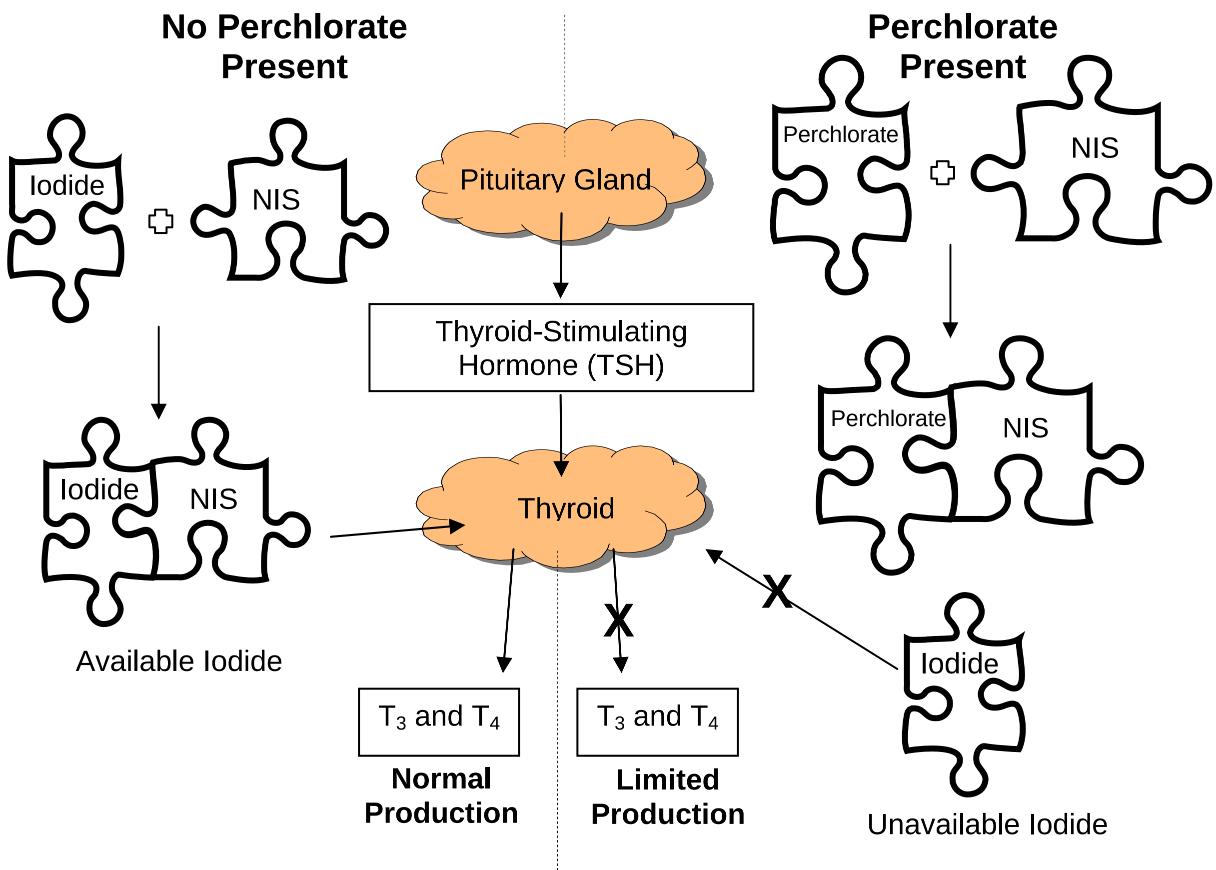
Detection of perchlorate in drinking water is critical to evaluating human health and ecological effects. This section of the appendix presents a general review of the thyroid gland, one of the more perchlorate-sensitive human systems, and discusses the effects of perchlorate exposure on the thyroid and non-thyroid related functions. MDA reviewed numerous scientific studies on the effect of perchlorate on the thyroid gland and on other human systems, as well as epidemiological (population studies) and animal toxicology studies. The primary literature reviewed by MDA included U.S. EPA's draft risk assessment Perchlorate Environmental Contamination: Toxicological Review and Risk Characterization (2002), and the NRC report entitled Health Implications of Perchlorate Ingestion (2005). The NRC of the NAS was asked to assess independently the adverse health effects of perchlorate ingestion from clinical, toxicological, and public-health perspectives. They were also asked to evaluate the relevant scientific literature and key findings underlying U.S. EPA's 2002 draft risk assessment. In response to the request, the NAS convened the Committee to Assess the Health Implications of Perchlorate Ingestion and published their comprehensive report in January 2005.

M.6.1 Thyroid Function

Current research demonstrates that the human thyroid gland is one of the more sensitive glands affected by perchlorate. The thyroid gland converts iodide, found in many foods that we eat, into thyroid hormones [thyroxine (T_4) and triiodothyronine (T_3)], which aid in regulating metabolic rates throughout the human body. Perchlorate affects the way that iodide is transported into various glands and systems throughout the body. For iodide to enter the thyroid and other glands and systems, it must bind to another

molecule, sodium (Na^+)/iodide (I^-) symporter or "NIS." Perchlorate has a similar shape and electric charge as iodide and readily binds with NIS. When NIS is bound to other non-iodide ions (perchlorate), the transport of iodide into the thyroid and other glands is inhibited. Exhibit M-4, Thyroid Hormone Production with and without Perchlorate Present, graphically displays what happens when perchlorate is present in the human body.

Exhibit M-4. Thyroid Hormone Production with and without Perchlorate Present



Proper thyroid function depends on the balance of the negative feedback loop of the hypothalamic-pituitary-thyroid (HPT) axis. The hypothalamus produces thyrotropin-releasing hormone (TRH) that travels to the pituitary gland and stimulates the synthesis of thyroid stimulating hormone (TSH). TSH initiates a series of transduction signals resulting in the synthesis and release of T_3 and T_4. Homeostasis is maintained by an endocrine negative feedback loop; increased circulating levels of T_3 and T_4 lead to a decrease in TRH and TSH secretions resulting, in turn, in decreased thyroid gland activity; conversely, decreased T_3 and T_4 levels in systemic circulation result in an increase in TRH and TSH secretions that stimulate the thyroid gland to increase its activities to synthesize and release additional T_3 and T_4 requires both the presence of sufficient iodide as well as TSH released from the pituitary gland. Feedback regulation

through changes to TSH levels protects against both hypothyroidism (deficiency of thyroid hormone) and hyperthyroidism (excess of thyroid hormone). The presence of perchlorate at sufficient doses can inhibit iodide uptake to the thyroid, eventually reducing thyroid hormone levels (T_3, T_4) if maintained for a prolonged period of time at a sufficient level to exceed thyroid compensatory mechanisms, such as the increased TSH production. The T_3 and T_4 thyroid hormones are responsible for regulating the body's metabolic rate, but also for stimulating the development and growth of many kinds of cells throughout the body including in the brain and central nervous system.

As shown in Exhibit M-4, when the transport of iodide into the thyroid is inhibited, there is a decrease in the production of T_4 and T_3. If, in spite of TSH-induced increases in thyroid function, the amount of iodine is still insufficient to keep up with the body's hormone demand, the serum thyroid hormone levels will decrease. For adverse health effects to occur in otherwise healthy adults, thyroid hormone production would likely have to be reduced by at least 75% for months or longer. (NRC, 2005) In sensitive populations (pregnant women, infants, children, and people with low iodide intake or thyroid dysfunction) the dose required to cause hypothyroidism may be lower. However, data are not available to determine the precise level of decreased production that would cause adverse health effects in those sensitive populations.

Humans obtain iodide by ingestion of food or water that contains it. The human body is able to compensate for iodide deficiency; therefore, thyroid hormone production is generally normal even when iodide intake is quite low. Hypothyroidism occurs only if daily iodide intake is below about 10 to 20 grams (about one-fifth to one-tenth of the average intake in the U.S.). However, iodide deficiency of that severity in pregnant women can result in neurodevelopmental deficits and goiter in their children. Lesser degrees of iodide deficiency may also cause significant neurodevelopmental deficits in infants and children. (NRC, 2005)

M.6.2 Perchlorate and the Thyroid

As described in Section M.6.1, perchlorate replaces iodide and results in a decrease of the normal production of thyroid hormones T_4 and T_3. To understand the effect of perchlorate ingestion on the thyroid, it is necessary to equate the concentration of perchlorate in drinking water with a daily intake level, in milligrams for example, to relate the concentration of perchlorate in each test to an amount that would need to be consumed.

The exposure factors established by U.S. EPA for converting a health-based dose level to a drinking water concentration were used to convert a daily dose of perchlorate (e.g., 10 milligrams) to a concentration of perchlorate in ground water (e.g., 5 milligrams (mg) per liter or 5 parts per million [ppm]). (U.S. EPA, 1997) The U.S. EPA-established methodology assumes that healthy adults weigh 70 kg (154 pounds) and drink 2 liters

(approximately 0.5 gallon) of water per day. Based on the above example, 10 mg per day times 1 day per 2 liters equals 5 mg per liter, as displayed below.

$$\frac{10\text{ mg}}{1\ \cancel{\text{day}}} \times \frac{1\ \cancel{\text{day}}}{2\text{ liters}} = \frac{5\text{ mg}}{\text{liter}} \qquad 5\text{ ppm }(5{,}000\text{ ppb})$$

The dose of perchlorate (in mg/kg per day) is multiplied by a standard body weight of 70 kg and divided by the number of liters (2 liters) that an adult consumes per day. This converts the concentration of the daily dose into mg per liter, which is approximately equivalent to ppm. For doses of perchlorate that are provided in mg/kg of body weight, the dose is multiplied by the body weight (70 kg) to calculate the total daily dose of perchlorate and equate a comparative ground water contamination. Exhibit M-5, Correlation of Doses and Concentration, presents the concentration of perchlorate in ground water in mg per liter, ppm, and ppb that would be necessary to achieve such a dose.

Exhibit M-5. Correlation of Doses and Concentration

Human and Animal Health Studies		**Groundwater Concentration**		
Dose (mg per day)	**Dose (mg/kg of body weight)**	**mg/liter**	**ppm**	**ppb**
0.001	0.000014	0.0005	0.0005	0.5
0.01	0.00014	0.005	0.005	5
0.05	0.0007	0.025	0.025	25
0.1	0.0014	0.05	0.05	50
0.5	0.007	0.25	0.25	250
1	0.014	0.5	0.5	500
10	0.14	5	5	5,000
100	1.4	50	50	50,000
250	3.6	125	125	125,000
500	7.14	250	250	250,000
1,000	14.3	500	500	500,000
5,000	71.4	2,500	2,500	2,500,000
10,000	142.9	5,000	5,000	5,000,000

U.S. EPA is responsible for setting appropriate drinking water standards. U.S. EPA makes these determinations based on hazard and exposure information and whether or not regulation of perchlorate would provide a meaningful opportunity for health risk reduction. MDA has reviewed available studies in which perchlorate was given to patients with hyperthyroidism and healthy subjects over various amounts of time to

determine the effects on thyroid function. As a caveat to the information provided below, it should be noted that the NRC indicated that there is no information on the effects of low level iodide uptake inhibition on iodide-deficient, hypothyroid or borderline hypothyroid pregnant women or neonates. The dosage estimates provided relate to healthy adults who are both euthyroid and iodide replete (see Greer et al., 2002) or to seriously hyperthyroid states followed by maintenance therapy under presumably normal iodide intake levels. Early medical literature during the 1950s and 1960s contained reports of successful treatment of more than 1,000 hyperthyroid patients with high levels of potassium perchlorate (between 400 and 2,000 milligrams per day) for many weeks or months. These dose values correspond to estimated drinking water concentrations (EDWCs)[3] of 200,000 to1,000,000 ppb. Among the patients were 12 pregnant women who had hyperthyroidism and were treated with 600 to 1,000 mg of potassium perchlorate per day (EDWCs: 300,000 to 500,000 ppb). One infant had slight thyroid enlargement that decreased soon after birth. No other abnormalities were reported in the infants. However, no thyroid function tests or neurodevelopmental evaluations were conducted, and the infants did not receive any follow up medical evaluation.

Perchlorate also was used in the 1950s and 1960s to treat hyperthyroidism associated with Graves' disease.[4] Perchlorate was not widely used to treat this disorder, and its use was curtailed when severe hematologic side effects were noticed including aplastic anemia[5] and agranulocytosis[6], and when better antithyroid drugs became available. (NRC, 2005) By 1984, another study administered potassium perchlorate to 18 people with hyperthyroidism caused by Graves' disease. (Wenzel and Lente, 1984) The high doses on the order of 900 mg per day were gradually reduced to an average of 93 mg per day. Absence of the antibodies indicated that the patients no longer had Graves' disease. Thus, one could consider treatment in the latter 12 months to be equal to administration of perchlorate to healthy people. Therefore, the results provide evidence that moderately high doses of perchlorate given chronically to people with a history of hyperthyroidism do not cause hypothyroidism. (NRC, 2005) There are no reports of the appearance of new thyroid disorders, thyroid nodules, or thyroid carcinomas in patients treated with potassium perchlorate for hyperthyroidism. (NRC, 2005)

---

[3] All EDWC values listed are based on the default adult drinking water consumption of 2.0 liters per day and the default adult body weight of 70 kilograms.
[4] According to the National Graves' Disease Foundation (2000), Graves' disease "represents a basic defect in the immune system, causing production of immunoglobulins (antibodies) which stimulate and attack the thyroid gland, causing growth of the gland and overproduction of thyroid hormone. Similar antibodies may also attack the tissues in the eye muscles and in the pretibial skin (the skin on the front of the lower leg).
[5] Aplastic anemia occurs when the bone marrow stops making enough blood-forming stem cells. (Aplastic Anemia and MDS International Foundation, Inc., 2005)
[6] Agranulocytosis occurs when there are an insufficient number of granulocyte type white blood cells. This can cause an individual to become susceptible to an infection or can be caused when white blood cells are destroyed faster than they can be produced. (Medline Plus, 2005)

Exhibit M-6 briefly summarizes the parameters and results of five more recent studies in which lower doses of perchlorate were given to healthy subjects over various amounts of time to determine the effects on thyroid function. Each study measured the amount percent decline of iodide uptake after varying dosages of perchlorate.

Exhibit M-6. Summary of Perchlorate Studies

Study	Subjects	Dosage and Duration	Results
Study 1 - Brabant et al., 1992	5 Men	200 grams of iodide daily for 28 days followed by 900 mg of perchlorate daily for 28 days	Concentration of TSH, T4, and total thyroid iodide content were slightly lower after administering perchlorate
Study 2 - Lawrence et al., 2000	9 Men	10 mg of perchlorate daily for 14 days	No change in the concentration of T4, T3, or TSH A 42% reduction of iodide uptake in the thyroid
Study 3 - Lawrence et al., 2001	8 Men	3 mg of perchlorate daily for 14 days	No statistically significant change in the rate of iodide uptake
Study 4 - Greer et al., 2002	16 men 16 women	0.02 mg/kg 0.1 mg/kg 0.05 mg/kg for a total of 14 days	For 0.02 mg/kg, a 16.4 percent decrease in the rate of iodide uptake For 0.1 mg/kg, a 44.7 percent decrease in the rate of iodide uptake For 0.5 mg/kg, a 67.1 percent decrease in the rate of iodide uptake
Supplemental Study 1 for Study 4 - Greer et al., 2002	1 man 1 woman	0.02 mg/kg 0.1 mg/kg 0.05 mg/kg for a total of 14 days	For 0.02 mg/kg, a 16.4 percent decrease in the rate of iodide uptake For 0.1 mg/kg, a 44.7 percent decrease in the rate of iodide uptake For 0.5 mg/kg, a 67.1 percent decrease in the rate of iodide uptake
Supplemental Study 2 for Study 4 - Greer et al., 2002	1 man 6 women	0.007 mg/kg daily for a total of 14 days	No change in the concentration of T4, T3, or TSH No change in the rate of iodide uptake in the thyroid

Study	Subjects	Dosage and Duration	Results
Study 5 - Braverman et al., 2005	13 Subjects	Placebo daily for 6 months 0.5 mg of perchlorate daily for 6 months (0.007 mg/kg) 3 mg of perchlorate daily for 6 months (0.04 mg/kg)	No change in the concentration of T4, T3, or TSH No change in the rate of iodide uptake in the thyroid

The results of the studies in which thyroid function was assessed in several ways are remarkably consistent. The study subjects were healthy men and women 18 to 57 years old, and no one was taking medications that might influence thyroid radioiodide independently of perchlorate. In the studies in which thyroid radioiodide uptake was measured, the baseline values varied somewhat among the subjects, but no more than expected in healthy people eating their usual diet. The normal range for 24-hour thyroid uptake of radioiodide in many places in the U.S. is between 10 and 30 percent, also reflecting variation in dietary iodide intake. Although individual study groups were small (4 to 10 subjects), the results were highly consistent within each treatment group in that the variance of the change, or lack of change, in thyroid radioiodide uptake during potassium perchlorate administration was similar to or less than the variance at baseline.

The effects of similar doses of potassium perchlorate on thyroid radioiodide uptake were similar. A daily perchlorate dose of 0.007 mg/kg (EDWC: 245 ppb) had no statistically significant effect in two studies (Greer et al., 2002; Braverman et al., 2005); a daily dose of 0.02 mg/kg (EDWC: 700 ppb) had a small effect (about 15 percent inhibition of thyroid iodide uptake) (Greer et al., 2002); and daily doses of 0.03 and 0.04 mg/kg (EDWCs: 1,050 and 1,400 ppb) had no effect in two other studies. (Lawrence et al., 2000; Braverman et al., 2005)

Perchlorate is still used to diagnose defects in the synthesis of thyroid hormones and as a treatment for patients who have developed hyperthyroidism after being exposed to the antiarrythmic drug amiodarone; however, perchlorate is rarely used to treat any type of hyperthyroidism in the U.S.

M.6.3 Nonthyroid Effects of Perchlorate

Exposure to perchlorate can cause other nonthyroid effects. Most human health effects that stem from perchlorate exposure are related to the disruption of the function of the NIS. The disruption is caused by perchlorate binding with the NIS, thereby inhibiting the NIS from binding with iodide. The NIS is present in the human body in

- Salivary glands;
- Mammary glands, especially during lactation;
- Stomach;
- Choroid plexus of the brain; and
- Ciliary body of the eye (Dohan et al., 2003).

Iodide and NIS functions in these tissues are not the same as in the thyroid. The iodide transported into those tissues is not further metabolized as it is in the thyroid gland. Instead, iodide is rapidly returned into the circulation or secreted into the saliva or breast milk. Iodide transport into these tissues has not been confirmed to be required for their normal function, with the possible exception of mammary tissue. Furthermore, TSH has been found to increase only the NIS content in thyroid tissue. Perchlorate acutely inhibits iodide transport in salivary and mammary tissue, but it does not appear to reduce the iodide content of breast milk. (NRC, 2005)

Very small amounts of the NIS have been detected in other tissues, including the heart, kidneys, lungs, and placenta. Perchlorate is not known to cause congenital malformations, but the relationship has not been well studied.

Some of the side effects of high doses of perchlorate – rashes, aplastic anemia, or agranulocytosis – might have been immunologic responses. Those effects could be caused by a direct toxic effect of perchlorate itself, a contaminant of it, or an immunologic reaction to the drug or a contaminant that is not known. The fact that the effects were dose-dependent argues for direct toxicity rather than an immunologic reaction. Regarding a possible immunologic effect of perchlorate, it is not possible to assess potential clinical effects from experiments in which high doses of perchlorate were added directly to immune cells *in vitro*. In summary, there is no evidence that regular ingestion of perchlorate in any dose causes immunologic abnormalities in humans. (NRC, 2005)

M.6.4 Animal Toxicology Studies

The pituitary-thyroid system of rats is similar to that of humans. For example, decreases in thyroid hormone production result in increased secretion of TSH, which then increases thyroid production and release of T_4 and T_3. However, differences in binding proteins, binding affinities of the proteins for the hormones, turnover rates of the hormones, and thyroid stimulation by placental hormones create important quantitative differences between the two species. Therefore, although studies in rats provide useful qualitative information on potential adverse effects of perchlorate exposure, they are limited in their utility for quantitatively assessing human health risk associated with perchlorate exposure.

There are several controversial issues regarding animal toxicology studies. One is the interpretation of results of rat studies that evaluated the effects of maternal perchlorate exposure on offspring brain development. In those studies, female rats were given ammonium perchlorate throughout pregnancy and into the postnatal period. Linear measurements of several brain regions of the male and female pups at several postnatal ages were compared with control values. Serious questions have been raised regarding the design and methods used in those studies. The NRC report agreed with some previous reviewers that the methodological problems, such as possible systematic differences in the plane of section across treatment groups, and the lack of a consistent dose-response relationship, make it impossible to conclude whether or not perchlorate exposure causes changes in brain structure.

Other studies that have received critical attention are rat studies that investigated the effect of maternal exposure on offspring neurobehavior. In the primary study, female rats were treated with ammonium perchlorate throughout pregnancy and into the postnatal period, and the offspring were evaluated with a battery of behavioral tests. Overall, the NRC report found that the functions evaluated (i.e., activity, auditory startle, learning, and memory) were appropriate but no significant effects of perchlorate were observed in any of the behavioral measures except an increase in motor activity in male pups on one day of testing. Because the tests lacked the sensitivity to detect subtle effects, the NRC report concluded that the data were inadequate to determine whether or not gestational or lactational exposure to perchlorate affects behavioral function in rats.

Concerns have also been raised over the significance of the results of a two-generation rat study in which benign thyroid tumors were observed in two male offspring. Both the parent generation and the offspring were given ammonium perchlorate before mating, during mating, gestation, and lactation, and until sacrifice. The NRC report concluded that the thyroid tumors in the offspring were most likely treatment-related, but that thyroid cancer in humans resulting from perchlorate exposure is unlikely because of the hormonally mediated mode of action and species differences in thyroid function.

High doses of perchlorate in humans with hyperthyroidism have caused side effects that could be considered immunologic responses; however, immunotoxicity studies in mice revealed no changes in immunologic function in response to perchlorate exposure. Therefore, the NRC report found that there is no evidence of a causal relationship between perchlorate ingestion and any biologically meaningful stimulatory or inhibitory effect on the immune system in rodents. The report concludes that the side effects in humans were probably toxic effects of the very high doses of perchlorate given to those patients.

M.6.5 Epidemiologic Studies

Numerous epidemiologic studies have examined the associations of environmental exposure to perchlorate in drinking water at levels between 4 and 120 ppb. These studies addressed abnormalities of thyroid hormone and TSH production in newborns, thyroid diseases (i.e., congenital hypothyroidism, goiter, and thyroid cancer), and cancer in infants and adults. (Lamm and Doemland, 1999; Brechner et al., 2000; Crump et al., 2000; F.X. Li et al., 2000; Z. Li et al., 2000; Schwartz, 2001; Morgan and Cassady, 2002; Kelsh et al., 2003; Lamm, 2003; Buffler et al., 2004)

Occupational studies of respiratory exposures up to 0.5 mg/kg perchlorate per day (EDWC: 17,500 ppb) have been conducted. These studies addressed the abnormalities of thyroid hormone and TSH production in adult workers. (Gibbs et al., 1998; Lamm et al., 1999; Braverman et al., 2005) Only one study has examined a possible relation between perchlorate exposure and adverse neurodevelopmental outcomes in children (e.g., attention-deficit-hyperactivity disorder [ADHD] and autism). (Chang et al., 2003) A number of the studies have samples that are too small to detect differences in the frequency of outcomes between exposure groups.

No studies have examined the relationship of perchlorate exposure to adverse outcomes among especially vulnerable groups, such as low-birth weight or preterm infants. In addition, the available studies do not assess the possibility of adverse outcomes associated with perchlorate exposure in infants born to mothers who had inadequate dietary iodide intake. Thus, no direct human data are available regarding a possible interaction between maternal iodide intake and perchlorate exposure.

Nearly all the studies were ecologic studies (i.e., general population studies), which include newborns and children, who are potentially most vulnerable to the effects of perchlorate exposure. Ecologic studies can provide supporting evidence of a possible association but cannot provide definitive evidence regarding cause. Perchlorate exposure of individuals is difficult to measure and was not assessed directly in any of the studies conducted outside the occupational setting. One study took perchlorate measurements directly from drinking-water samples taken from faucets in Chile. (Crump et al., 2000)

The design of an ecologic study is inherently limited with respect to establishing causality. However, results of ecologic studies can be informative when combined with other data on the biology of the thyroid gland, experimental studies of the effects of acute exposure to perchlorate, and studies of occupational perchlorate exposure.

Acknowledging that ecologic data alone are not sufficient to demonstrate whether or not an association is causal, the NRC report provided evidence bearing on possible associations and reached the following conclusions regarding the proposed association of perchlorate exposure with various health end points:

- Congenital hypothyroidism (deficiency of thyroid hormone production). The available epidemiologic evidence is not consistent with a causal association between perchlorate exposure and congenital hypothyroidism as defined by the authors of the studies reviewed by the NRC report. All studies of that association were negative, meaning that perchlorate exposure was not found to cause congenital hypothyroidism.

- Changes in thyroid function of newborns. The available epidemiologic evidence is not consistent with a causal association between exposure to perchlorate in the drinking water during gestation (up to 120 ppb) and changes in thyroid hormone and TSH production in normal-birth weight, full-term newborns. Most of the studies show neither significantly lower T_4 production nor significantly higher TSH secretion in infants born in geographic areas in which the water supply had measurable perchlorate concentrations. However, no data are available on the association of perchlorate exposure with thyroid dysfunction in the groups of greatest concern, low-birth weight or preterm newborns, offspring of mothers who had iodide deficiency during gestation, or offspring of hypothyroid mothers. There have been no adequate studies of maternal perchlorate exposure and neurodevelopmental outcomes in infants.

- Neurodevelopmental outcomes. The epidemiologic evidence is inadequate to determine whether or not there is a causal association between perchlorate exposure and adverse neurodevelopmental outcomes in children. Only one pertinent study has been conducted, an ecologic study that examined the association of perchlorate exposure with autism and ADHD. Although the NRC report considered the inclusion of ADHD plausible, it questions the appropriateness of autism as an end point given that autism has not been observed in the spectrum of clinical outcomes in children who had congenital hypothyroidism and were evaluated prospectively. (Rovet, 1999, 2002, 2003)

- Hypothyroidism and other thyroid disorders in adults. The evidence from chronic, occupational exposure studies and ecologic investigations in adults is not consistent with a causal association between perchlorate exposure at the doses investigated and hypothyroidism or other thyroid disorders in adults. In occupational studies, perchlorate doses as high as 0.5 mg/kg per day (EDWC: 17,500 ppb) have not been associated with adverse effects on thyroid function in workers. However, the small sample sizes in some studies may have reduced the ability to identify important differences, and the studies were limited to those workers who remained in the workforce.

- Thyroid cancer in adults. The epidemiologic evidence is insufficient to determine whether or not there is a causal association between exposure to perchlorate and thyroid cancer. Only two pertinent ecologic studies have been conducted. In one, the number of cancer cases was too small to have a reasonable chance of detecting an

association if one existed. (Li et al., 2001) In the second (Morgan and Cassady, 2002), subjects were exposed to both perchlorate and trichloroethylene. It was not possible to adjust for potential confounding variables in either study.

M.7 Ecological Impacts

The potential ecological impacts of perchlorate are discussed in this section. The characteristics and behavior of perchlorate in the environment are explained, followed by a discussion of ecotoxicology in aquatic and terrestrial environments.

M.7.1 Chemical Characterization and Fate in the Environment

The perchlorate anion (ClO_4^-) forms weak bonds with cations (positively charged ions) to produce perchlorate salts (e.g., ammonium, lithium, potassium, and sodium perchlorate salts) and weak complexes. These salts and acids are very soluble in water (>200 grams/liter) with densities greater than water. (Mendiratta et al., 1996) Once dissolved, perchlorate is extremely mobile in water systems. Limited published information is available on the fate of perchlorate in the environment. The scientific literature does not contain environmental partitioning coefficients or degradation rates. The perchlorate ion is highly charged; however, there is no evidence that perchlorate is attracted to soil particles. Therefore, it is likely to move through soil as it does in water. Perchlorate in the soil may be re-released into the environment via leaching from irrigation and/or rainfall. Perchlorate is not expected to be in the atmosphere because it has low vapor pressure; thus, it will not volatilize from water systems or the land. Perchlorate particles can be suspended in the air but return to the ground via dry deposition (gravity) or wet deposition (precipitation).

Perchlorate is chemically stable, meaning that it requires a high amount of energy to break it down. Its stability is based on its atomic structure: four oxygen atoms surrounding each chlorine atom. This results in perchlorate’s resistance to degradation and/or biotransformation under most environmental conditions, allowing it to persist for many decades in terrestrial and aquatic systems.

M.7.2 Ecotoxicity

The USAF sponsored studies that evaluated the effects of perchlorate in aquatic systems on primary and secondary production, toxicity to aquatic organisms, decomposition, biodegradation, and bioaccumulation. (USAF, 2002) Terrestrial ecotoxicity is also discussed below.

Aquatic Environment

Studies indicate that the presence of perchlorate has little effect on common processes in the aquatic environment. For example, photosynthesis in aquatic systems was minimally affected by high aquatic perchlorate concentrations. High levels (1,000 ppm) of perchlorate can adversely affect marine phytoplankton or bacterioplankton (secondary production). However, coastal waters are large areas constantly circulating and mixing, and it is unlikely such high concentrations of perchlorate would be encountered except for short periods of time. (USAF, 2002)

Likewise, respiration, as a measure of decomposition in marine and freshwater sediments and wetland peat, was not adversely affected by high perchlorate concentrations. It is unlikely that concentrations exceeding this level would be encountered in sediments except in small regions in direct contact with solid propellant for extended periods of time. Perchlorate concentrations in sediments did not tend to decrease over a seven-day incubation period. Anaerobic bacteria are capable of respiring perchlorate and this process has been observed in perchlorate-contaminated sediments. However, this ability tends to be associated with chronically contaminated systems. (USAF, 2002)

Perchlorate concentrations nearing 30 ppm had no effect on the stickleback, a freshwater to brackish water fish. The study evaluated mating and the birth and growth of young fish. Although morphological or behavioral abnormalities may occur as the young fish matures, these characteristics were not evaluated in this study. (USAF, 2002) Effects measured as growth and mortality, ranged from a No Observed Effects Level (NOEL) of 10 mg/liter in the water flea (*Ceriodaphnia dubia*) to a NOEL of 155 mg/liter in a fresh water fish (*Pimephales promelas*). The Lethal Concentration for 50 percent of the water flea population (LC_{50}) was 66 mg/liter. (U.S. EPA, 2002)

Several studies have evaluated the effect of perchlorate on algae/bacteria and animals in and around an aquatic environment. A USAF study (USAF, 2002) showed that both the microbial and fish components accumulated significant levels of perchlorate. Susarla et al., 2000 also found that perchlorate can accumulate in aquatic vascular plants. Further, both the USAF and Smith et al., 2001 found that perchlorate could be passed on to following trophic levels. The U.S. Army Corps of Engineers study (Condike, 2001) demonstrated that fish tissue concentrations of perchlorate exceed comparable concentrations detected in the water, indicating the bioaccumulation of perchlorate in fish tissue, a conclusion also supported by Smith et al., 2001.

Terrestrial Environment

In the terrestrial environment, perchlorate can influence natural soil processes and can be taken up by plants. For example, in the presence of high levels of perchlorate (between 100 and 1,000 ppm), soil samples exhibited significant decreases in respiration activity

indicating that decomposition of perchlorate, nutrient recycling, and potentially plant growth will slow down. (USAF, 2002)

Phytoremediation studies have found that terrestrial plants will uptake perchlorate, first in the leaves, followed by stems, then roots, and that perchlorate concentrations are usually greater than in surrounding soil samples. (Susarla et al., 2000; Parsons, 2001) However, perchlorate was not detected in terrestrial birds, mammals, or insects when soils were reported to contain 0.3 to 0.4 mg/kg of perchlorate. Perchlorate breakdown products – chlorate, chlorite, and chloride – were detected in plant tissues but were not quantified.

M.8 Guidance and Recommendations

No Federal drinking water standard for perchlorate has been established. Although MDA is not responsible for evaluating the health effects or potential risk of perchlorate exposure, it will adhere to any applicable drinking water standards or regulations promulgated by the U.S. EPA or state authorities. Pending the establishment of a drinking water standard, MDA will continue to mitigate potential introduction of perchlorate into the environment by properly disposing of rocket fuel debris resulting from non-normal detonations/explosions of boosters on the pad.

Section M.8.1 discusses the existing Federal guidance on perchlorate from U.S. EPA and the NRC. Section M.8.2 provides explanations of two of the existing state ground water guidance levels that were developed for Massachusetts and California. Section M.8.3 describes other scientific studies that have made recommendations regarding perchlorate levels.

Many of the studies express their scientific findings in terms of an RfD, which is determined based on body weight and is expressed in mg/kg. An RfD is a reference dose level and in itself is not considered a standard that can be implemented as a regulation. To determine a drinking water standard for perchlorate, a number of ppb allowed in drinking water must be calculated. A drinking water standard is developed based on a number of factors, including the RfD, potential exposure to sensitive populations, and possible exposure to perchlorate from other sources (e.g., food, milk).

For example, a recent study by the Environmental Working Group[7] found perchlorate in 31 of 32 California supermarket milk samples taken from supermarkets in Los Angeles and Orange Counties. The levels of perchlorate measured in these samples ranged from non-detectable levels to 3.6 ppb. (FDA, 2005) In a separate study, the Food and Drug Administration found perchlorate in several samples of milk taken from retail locations

[7] The Environmental Working Group is a nonprofit research organization, which uses “the power of information to educate the public and decision-makers about a wide range of environmental issues, especially those affecting public health.”

around the country. Perchlorate levels in the milk from these retail locations ranged from 3.16 to 11.3 ppb in 101 out of 104 samples, with perchlorate levels that were not quantifiable in three samples. (FDA, 2005) The mean measured perchlorate level for this study was 5.76 ppb for the 104 samples. The Food and Drug Administration also cited a 2003 Texas Tech University that found perchlorate levels ranging from 1.7 to 6.4 ppb in seven fluid milk samples and 1.1 ppb in one evaporated milk sample. (FDA, 2005)

A separate study completed by Texas Tech University also considered perchlorate content in 47 samples of dairy milk and 36 samples of human milk. Perchlorate was detected in 46 of the dairy milk samples and in all of the breast milk samples. (Kirk et al, 2005) The mean perchlorate levels were 2.0 micrograms/liter in dairy milk and 10.5 micrograms/liter in breast milk, with maximum levels of 11 and 92 micrograms/liter, respectively. (Kirk et al., 2005) Although the Texas Tech study relied on a relatively small sample size the researchers found that perchlorate in breast milk is not well correlated with the water the mothers are drinking. The study hypothesizes that perchlorate consumption comes primarily from food rather than water or beverages. (Kirk et al., 2005)

Iodine-deficient vegetarians (especially women of child-bearing age) have been proposed to be a sensitive, perchlorate-susceptible population; however, studies reviewed by Fields, et al. (2005) indicate that vegetarian diets do not necessarily lead to iodine deficiency and that vegans[8] may actually have excess iodine intake. The authors question the necessity of applying the 10-fold default uncertainty factor (UF) for intraspecies (i.e., within human) variability to protect this hypothetical and unlikely subpopulation.

M.8.1 Federal Guidance

This section provides a description of the recommended guidance related to perchlorate as established by U.S. EPA and the NRC. Each organization reviewed and analyzed existing studies to support its recommendation.

U.S. EPA Analysis and Recommendation

U.S. EPA's perchlorate RfD comes from the technical review of the "Health Implications of Perchlorate Ingestion" by the NRC of the NAS (NRC, 2005). Iodide uptake inhibition was determined to be the key biochemical event that precedes all potential thyroid-mediated effects of perchlorate exposure. Because iodide uptake inhibition is not an adverse effect but a biochemical change, this is a NOEL. The use of a NOEL differs from the traditional approach to deriving an RfD, which bases the critical effect on an adverse outcome. Using a no adverse effect that is upstream of the adverse effect is a

---

[8] In this instance the term "vegan" applies to someone who is a strict vegetarian; and therefore, consumes no animal food or dairy products.

more conservative and health-protective approach to perchlorate hazard assessment. The resulting official RfD established by U.S. EPA was 0.0007 mg/kg per day of perchlorate. This corresponds to estimated drinking water equivalent level of approximately 24.5 ppb.[9] This level is not a Federal drinking water standard but is consistent with the recommended RfD included in the NRC January 2005 report. (U.S. EPA, 2005b)

The National Academy of Science, National Research Council Analysis and Recommendation

The NRC report on perchlorate exposure and human health, entitled *Health Implications of Perchlorate Ingestion*, emphasized that its RfD recommendation differs from the traditional approach to deriving the RfD in that it recommended using a no adverse effect rather than an adverse one. (NRC, 2005) The report reviewed the human and animal data and found that the human data provided a more reliable point of departure (POD) for the risk assessment than the animal data. The NRC report recommends using clinical data collected in a controlled setting with the relevant routes of exposure to derive the RfD.

The NRC report also did not recommend using the available epidemiologic studies to derive the POD for the risk assessment based on limitations of ecological studies discussed in Section 5.5. Instead, the NRC report recommended using the Greer et al. (2002) study in which groups of healthy men and women were administered perchlorate at 0.007 to 0.5 mg/kg per day (EDWC: 245 to 17,500 ppb) for 14 days. That study identified a NOEL for inhibition of iodide uptake by the thyroid at 0.007 mg/kg per day (EDWC: 245 ppb). The NRC report concluded that the NOEL value from Greer et al. (2002) is a health-protective and conservative POD and is supported by the results of a six-month study of 0.007 mg/kg per day (EDWC: 245 ppb) in a small group of healthy subjects, a four-week study of higher doses in healthy subjects, the studies of perchlorate treatment of patients with hyperthyroidism, and extensive human and animal data that demonstrate that there will be no progression to adverse effects if no inhibition of iodide uptake occurs.

The report's recommendations would lead to an RfD of 0.0007 mg/kg per day. This corresponds to estimated drinking water concentration of approximately 24.5 ppb. That value is supported by other clinical studies, occupational and environmental epidemiologic studies, and studies of long-term perchlorate administration to patients with hyperthyroidism. The report concluded that an RfD of 0.0007 mg/kg per day should protect the health of even the most sensitive populations. The NRC report acknowledges that the RfD may need to be adjusted upward or downward on the basis of future research.

---

[9] A drinking water equivalent level is a conversion of the reference dose to a drinking water concentration taking body weight and water consumption into consideration.

Department of Defense

MDA will follow the perchlorate guidance developed by the DoD that establishes 24 ppb as the current level of concern for managing perchlorate found on DoD sites. The level of concern is based on the RfD established by the NRC study, which was subsequently adopted by the EPA. Where sampling indicates perchlorate concentrations above the level of concern, DoD Components are directed to conduct site-specific risk assessments. If a risk assessment indicates perchlorate concentrations could potentially result in adverse health effects, the site will be prioritized for appropriate risk management. In addition, DoD Components will: (1) assess for off-range migration of perchlorate from operational ranges; (2) test quarterly for perchlorate at DoD-owned drinking water systems until they are satisfied that concentrations are likely to remain below the level of concern; and (3) sample semi-annually at permitted point sources where the use of perchlorate is associated with processes related to the manufacture, maintenance, processing, recycling or demilitarization of military munitions. (DoD, 2006) Sampling results will continue to be maintained in the perchlorate database developed pursuant to the September 29, 2003, "Interim Policy on Perchlorate Sampling," which this policy statement supersedes. (DoD, 2003)

M.8.2 State Guidance

Exhibit M-7 shows state advisory levels for perchlorate that were established as of April 2005.

Exhibit M-7. State Perchlorate Advisory Levels (as of April 20, 2005)

State	Advisory Level	Supplemental Information
Arizona	14 ppb	1998 health based guidelines for child exposures
California	6 ppb	Public health goal – California expects to propose a maximum contaminant level in 2005
Maryland	1 ppb	Advisory level
Massachusetts	1 ppb	Advisory level for children and at risk populations – Massachusetts proposed a maximum contaminant level of 1 ppb and started the evaluation process
Nevada	18 ppb	Public notice standard
New Mexico	1 ppb	Drinking water screening level
New York	5 ppb	Drinking water planning level
	18 ppb	Public notification level
Texas	17 ppb	Residential protective cleanup level
	51 ppb	Industrial/commercial protective cleanup level

Source: U.S. EPA, 2005c

The remainder of this section describes the RfD and guidance levels implemented by the states of Massachusetts and California, and how their decisions were arrived at based on existing scientific research.

Massachusetts Department of Environmental Protection

To establish an RfD for perchlorate, the Massachusetts Department of Environmental Protection applied standard U.S. EPA UFs to the lowest observed adverse effect levels (LOAELs) for animals and humans. (U.S. EPA, 2002a and b; Massachusetts Department of Environmental Protection, 2004) Several sets of UFs were identified and applied to the animal and human LOAELs to arrive at a number of RfDs that span a range of possible true values. The RfD value at the higher end of this range is only 1.3 times the value in the lower end of the range. Since the Massachusetts Department of Environmental Protection as a rule develops a single RfD and not a range, the value of 0.00003 mg/kg per day (EDWC: 1 ppb) was selected as the point estimate for the RfD.

California Environmental Protection Agency

The California Environmental Protection Agency's (California EPA) Public Health Goal is based on the same human clinical study used in the analysis for NASA as described in Section 8.3 below. (Greer et al., 2002; California EPA, 2004) Rather than focusing on T_4 levels, California EPA selected iodide uptake inhibition as the critical effect. Using benchmark dose modeling, a 5 percent decrease in 24-hour iodide uptake ($BMDL_{05}$) was estimated to occur at a dose of 0.0037 mg/kg per day (EDWC: 130 ppb). After the application of UFs and exposure duration, the resulting RfD is 0.00037 mg/kg per day. Using a tap water consumption rate and body weight ratio of 25.2 kg/day per liter for the 95th percentile value of the pregnant woman population and a relative source contribution of 60 percent, the estimated drinking water concentration of 6 ppb of perchlorate was determined.

On August 11, 2005 the California Developmental and Reproductive Toxicant Identification committee, an independent scientific panel, decided against adding perchlorate to the Proposition 65 list of chemicals known to the state of California to cause birth defects or other reproductive harm. The committee can only list a substance if it has been "clearly shown" to cause reproductive toxicity. A decision that a substance falls short of the "clearly shown" standard does not mean that the committee believes that the substance is non-toxic. (California Office of Environmental Health Hazard Assessment, 2005)

M.8.3 Other Recommendations

This section describes three other studies that resulted in the recommendation of a drinking water advisory level for perchlorate. These recommendations are not Federal

drinking water standards but add to the general scientific knowledge base regarding perchlorate.

Dollarhide Analysis and Recommendation

As in the California EPA (2004) analysis, the RfD determined by Dollarhide was based on the Greer et al. (2002 study with iodide uptake inhibition as the critical effect. (Dollarhide et al., 2002) However, the benchmark response (an adverse effect, used to define a benchmark dose from which an RfD can be developed) was set at 20 percent inhibition ($BMDL_{20}$) rather than 5 percent inhibition. Therefore, the POD for derivation of the RfD was a $BMDL_{20}$ of 0.02 mg/kg per day. After consideration of UFs and exposure duration, the resulting RfD is 0.002 mg/kg per day. This corresponds to an average drinking water concentration of approximately 65 ppb.

Strawson Analysis and Recommendation

In this analysis, the RfD is based on an epidemiological study of elementary school children (ages 6 to 8) in three regions of Chile with varying degrees of perchlorate contamination. (Crump et al., 2000; Strawson et al., 2003) The drinking water exposure levels were estimated to be 0; 4 to 7; or 100 ppb. There were no effects on T_4 levels in any of the populations following exposure throughout their life (including *in utero*). Therefore, the POD for derivation of the RfD was a free-standing No Observed Adverse Effect Level (NOAEL) of 0.006 mg/kg per day (estimated daily dose based on drinking water concentration). After consideration of UFs and exposure duration, the resulting RfD is 0.002 mg/kg per day. This corresponds to an average drinking water concentration of approximately 65 ppb. A major limitation of the Crump et al. (2000) study is that Chilean children have much higher iodine intake (10-fold) than U.S. children of the same age. Therefore, this study cannot be expected to accurately predict levels of perchlorate exposure associated with adverse effects in populations with normal iodine intake.

Crump and Gibbs Analysis

Crump and Gibbs (2005) performed benchmark calculations for perchlorate using human data from three previous perchlorate studies - Lamm et al. (1999), Greer et al. (2002), and Braverman et al. (2005). They determined that the statistical lower bound on the benchmark dose was between 0.36 - 0.92 mg/kg per day for serum thyroid hormone and 0.21 - 0.56 mg/kg per day for free T4 index. These benchmark dose level values required to cause hypothyroidism in adults would be in agreement with the value of 0.4 mg/kg per day that was obtained by the NRC report (2005).

Exhibit M-8 below provides a summary of the guidance and recommendations discussed in Section M.8. This exhibit shows the citation, a description, and the critical endpoints

of the scientific study from which the agencies or organizations based their recommendation. The exhibit also provides a side-by-side comparison of the POD, UFs, and RfD values.

Exhibit M-8. Comparison of Health Criteria Values for Perchlorate Derived by Different Agencies/Groups

	U.S. EPA (2002b)	NRC (2005)[13]	MA Department of Environmental Protection (2004)	California EPA (2004)	TERA (Dollarhide et al., 2002)	TERA (Strawson et al., 2003)

APPENDIX N
IMPACTS OF RADAR ON WILDLIFE

IMPACTS OF RADAR ON WILDLIFE

N.1 Introduction

This appendix responds to comments from the USFWS on the Draft BMDS PEIS by providing an analysis of the impacts from radar on wildlife. Specifically, this appendix provides

- Background information including electromagnetic radiation (EMR) wavelengths of concern, radar operations, and characteristics unique to BMDS radars;
- Analysis of biological effects including absorption of EMR, basis for the 1999 Institute of Electrical and Electronics Engineers (IEEE) Standard to Protect Humans from EMR Exposure, thresholds for effects in birds, and studies of effects of EMR on migrating birds;
- Exposure assessment considering bird migration, radar operation, and estimates of duration and magnitude of exposure; and
- Impact characterization including individual and population risks, uncertainties, and mitigation measures.

Concerns raised by the USFWS include consideration of

- The potential effects of radar on very large flocks of migrating birds;
- The sufficiency of evidence to support the statement that no significant adverse impacts to birds would occur even if a bird is not within the most intense area of the beam for any considerable length of time;
- An analysis to describe what constitutes a "relatively small" beam size;
- Description of the potential adverse effect to birds from radar operation;
- Discussion of the potential of using Next Generation Weather Radar (NEXRAD) to help evaluate when large flocks may be in the testing area; and
- The fact that arctic foxes, which are very efficient predators, are present in areas where the COBRA DANE radar operates, and would quickly remove evidence of any bird kills.

The USFWS indicated that the 1993 Final Ground-Based Radar Family of Radars EA report used to support statements concerning potential effects of radar on migrating birds was out of date and inadequate for drawing conclusions of no harm. Some of the qualitative statements concerning no harm to birds can be supported by more quantitative data than was presented in the 1993 report. To do this it was necessary to first review the analyses provided in Appendix A of the 1993 report (Section N.2 of this appendix), and then describe additional quantitative analyses conducted to estimate the probability of harm to populations of migrating birds for this PEIS (Sections N.3 through N.7 of this appendix).

N.2 Review of 1993 EA Analysis of Potential Effects on Migrating Birds

As stated in the Draft BMDS PEIS, the 1993 Final Ground-Based Radar Family of Radars EA analyzed potential impacts on wildlife from EMR on migrating birds that might fly through the path of the radar beams. That analysis concluded that because the main beam would normally be in motion, it would be extremely unlikely that a bird would remain within the most intense area of the beam for any considerable length of time. That analysis also noted that the size of the beam is "relatively small," further reducing the probability of birds remaining within this limited region of space, even if the beam remained stationary. (U.S. Army Space and Missile Defense Command, 2003) The quantitative analyses supporting that conclusion were presented in part in Appendix A of the 1993 EA. (U.S. Army Space and Strategic Defense Command, 1993) The key points of this analysis are presented below.

To estimate a radar power density that might represent a lower threshold for adverse effects in birds based on heating from EMR at frequencies of 8 to 12 gigahertz (GHz), the analysis used data from rats indicating behavioral changes occurring at energy absorption rates of 4 watts per kilogram body weight (W/kg bw) over relatively long periods of time. The American National Standards Institute (ANSI) used the rat exposure studies and a safety factor of 0.1 applied to the 4 W/kg level to derive a maximum exposure level. Considerations such as the relative body size and EMR penetration depth in biological tissues at 10 GHz were used to establish the ANSI 1982 C95.1 limit for continuous human exposure to 10 GHz EMR expressed as a power density of 5 milliwatts per square centimeter (mW/cm^2). That value assumes the polarization of the EM field is aligned with the long axis of the body; other orientations would result in lower EM power absorption rates. In 1991, the IEEE revised that standard based on additional considerations to 10 mW/cm^2 averaged over six minutes, with a peak electric field (E) not to exceed 100,000 volts per meter (V/m) for controlled populations (i.e., occupational exposures). For uncontrolled populations (i.e., the public), the maximum exposures were set to 5.3 to 8 mW/cm^2 for frequencies from 8 to 12 GHz (with averaging times ranging from 11.3 to 7.5 minutes).

To estimate risks to migrating birds from XBR beams, the 1993 EA evaluated the potential for the radar beams to cause heating of bird tissues. Because the metabolic rate associated with sustained flight generally is 7 to 10 times resting metabolic rate, and for peak flight bursts might be as high as 20 times resting metabolic rate, the analysts assumed that birds should be able to tolerate an additional thermal load equivalent to 1 times their basal metabolic rate. The analysts therefore estimated a specific absorption rate (SAR) for birds that, if averaged over the entire body of the bird, would be equivalent to the resting metabolic rate.

Metabolic rates of birds vary with body weight; empirically derived allometric models are available to relate metabolic rate to body weight for different groups of birds (e.g., passerines, seabirds). In general, passerines have higher resting metabolic rates than other groups of birds. (Lasiewski and Dawson 1967) The 1993 EA Appendix A does not specify which allometric equations were used. The analysts noted further that there will be variation in absorption of EM for a given radar beam power density at a given frequency (and wavelength) as a function of bird size. They calculated that for birds weighing between 25 grams (g) and 3.5 kilograms (kg), i.e., from warbler to eagle or goose-sized birds, EMR power densities that would deliver an energy input equivalent to the resting metabolic rate would range from between 38 and 61 mW/cm^2. For the Aplomado falcon (*Falco femoralis*) in particular, the analysis indicated that the power density would have to exceed 42 mW/cm^2 to cause thermal loading equal to 1 times the metabolic rate of the bird.

Finally, based on a volumetric analysis of the proportion of airspace over a radar that would include the radar beam at power densities exceeding 38 to 61 mW/cm^2 averaged over a six-minute interval, analysts concluded that birds in flight had a less than one percent risk of incurring harm from a beam in motion. Specifically, analysts estimated that 0.014 to 0.025 percent (i.e., 1/4,000 to 1/7,000) of the airspace surrounding a radar might contain the beam at any given time. Details of the volumetric calculations were not provided. Note that a six-minute averaging time is likely to be very much longer than is relevant for a bird passing through a moving radar beam. Thus, the EMR power densities of 38 to 61 mW/cm^2, estimated to be thresholds for thermal loading effects in birds, are more conservative than necessary for shorter duration exposures, as discussed below.

N.3 Overview of Appendix

The assessment in this appendix of potential impacts of BMDS radars on migrating birds, particularly during testing phases, focuses on potential duration and magnitude of exposure of birds encountering beams, as well as the likelihood that birds might encounter the beams. This analysis includes review of the most recent basis for the IEEE standards for human exposure to EMR to determine if the bases for those standards have changed. As part of this analysis, reference hazard values were developed for migrating birds that are somewhat more conservative than the ones developed for birds of different sizes for the 1993 EA. Due to the sensitive nature of specifications of individual radars in the BMDS program, radars have been analyzed by category. In some cases, the most powerful radar in operation in each category is well known, with many published sources describing it. Where there is the potential of risk of impact to some birds, the specific radar type and the conditions under which a risk to migrating birds might exist is identified. For instances where a potential risk exists, mitigation measures are provided.

N.4 Background on Radar Systems

The BMDS program includes a large number of different types of radar systems for surveillance, detection, and tracking of missiles. These radar systems are described in Appendix E of this PEIS. Because there are many types of radar systems, it is necessary to provide background on the relationship between EMR frequency and potential for absorption of EMR by animals of different sizes. This discussion is provided in Section N.4.1. Section N.4.2 of this Appendix provides an overview of several types of calculations relevant to estimating radar EMR at varying distances from the source. Section N.4.3 evaluates the potential effects of the proposed BMDS radars on migrating birds.

N.4.1 EMR Wavelengths of Concern

EMR consists of inter-related E and magnetic (H) fields that oscillate at the sending frequency and travel at the speed of light. EMR frequency (f) and wavelength (λ) are related according to the equation:

Equation 1

$$\boldsymbol{\lambda = c/f}$$

where

λ	= wavelength in meters (m)
c	= speed of light (3×10^8 m/second)
f	= frequency in Hertz (Hz; cycles/second)

To facilitate later discussion, Exhibit N-1 shows the relationship between EMR frequency in megahertz (MHz) and wavelength in meters for selected frequencies between 10 MHz and 12,000 MHz.

Exhibit N-1. EMR Penetration Depth in Muscle Tissues vs. Frequency/Wavelength

Frequency (MHz)	Band	Wavelength (meters)	Penetration depth in muscle (cm)	Biological entity of similar size
10	HF	30		
30	VHF	10		
70	VHF	4.3		human
100	VHF	3	6.2	human
300	VHF/UHF	1	3.3	goose
435	UHF	0.69		eagle
650	UHF	0.46		bobwhite, rat
915	UHF	0.33		plover, robin
1,000	UHF/L	0.30	2.5	catbird
2,000	L/S	0.15	2.0	swallow, mouse
2,450	S	0.12		goose or eagle head
3,000	S	0.10	1.7	warbler
4,000	S/C	0.075		
5,000	C	0.06	1.0	
7,500	C	0.04		robin head
8,000	C/X	0.0375		
10,000	X	0.03	0.4	warbler head
11,000	X	0.0273		
12,000	X	0.025		

MHz = megahertz; HF = high frequency, VHF = very high frequency, UHF = ultrahigh frequency; L = long; S = short; C = compromise between X and S bands.
Source for penetration depth: AFRL 2005, Figure 2.

EMR is reflected or absorbed by different materials and objects to varying degrees depending on several parameters, including the material surface characteristics, its conductivity/impedance, the size and shape of the object relative to the wavelength of the incident EMR field, and orientation of the object relative to the incident field. Absorption of EMR is maximal when the long-axis of the object (e.g., animal body) is oriented in the direction of the electric field vector, i.e. the incident plane wave is perpendicular to the body. When wavelengths are much shorter than the length of an animal body, EMR is absorbed in the skin surface facing the source. For wavelengths approximating twice the length of the body, the body itself acts as an antenna to enhance the coupling of the EMR energy into the body.

Dosimetry studies for humans have demonstrated that maximum energy transfer occurs when the height of an individual approximates four-tenths the length of the EMR

wavelength. The frequency of maximal absorption is called the resonance frequency, and for humans, it is between 70 and 100 MHz.

The depth to which radar EMR can penetrate biological materials generally decreases with increasing frequency and depends on the impedance of the material. Measured penetration depths for muscle tissue are included for some frequencies in Exhibit N-1; penetration depths for fat are higher (see Figure 2 in AFRL 2005). Thus, the higher the EMR frequency, the more shallow the penetration and the lower the potential for warming effects in an animal, with XBR penetrating only a fraction of a centimeter into muscle tissues.

Exhibit N-1 includes the corresponding wavelengths in meters for comparison with birds of different sizes (considering the length of the body from head to base of tail). For reference, Exhibit N-1 also shows the human and laboratory rat and mouse. Because it is possible for the head (or other body parts) of an animal to have its own resonance and absorption characteristics, estimates of the size of the head of a few types of birds is included as well. From Exhibit N-1, it is clear that the EMR frequencies of most concern for migrating birds range from 300 to 10,000 MHz (wavelengths from about 100 to 3 cm, respectively). EMR with shorter or longer wavelengths is outside of the principal resonant frequencies for migrating birds.

N.4.2 Radar Basics

Radar is an acronym for **RA**dio **D**etection and **R**anging. The radar frequencies are organized by bands: UHF band (300 MHz to 1 GHz), L-band (1 to 2 GHz), S-band (2 to 4 GHz), C-band (4 to 8 GHz), and X-band (8 to 12 GHz).

The power in a radar beam at some distance from the source depends on the power at the source, radar power efficiency, antenna gain, and distance from the source. It is often expressed as a power density (S) in units of watts per unit area. For radar performance calculations, power density is expressed in watts per square meter, and for biological effects, in mW/cm^2. Due to spherical spread, S decreases with the square of the reciprocal of the distance from the radar.

Radar antenna radiation fields are divided into near field and far field regions. Within the far field region, the angular EMR power density distribution is essentially independent of the distance from the radar and the E and H field vectors form a plane-wave. Within the near field region, the angular EMR power density distribution is a function of range. In the far field, the power density S is calculated as follows:

Equation 2

$$\mathbf{S} = (\mathbf{P} / 4\,\pi\,\mathbf{r}^2) \cdot \mathbf{G}_T$$

where

S is the power density in watts per unit square meter
P is the radiated peak power
r is the range in meters
$\mathbf{G}_T$ is the transmitter antenna gain in a particular direction

The antenna gain (G_T) describes the degree to which the radar is able to concentrate its power in a given direction and is highest along the main axis of the radar beam. The gain in Equation 2 is expressed as the ratio of the maximum radiation intensity of the actual antenna in a given direction over the radiation intensity of an isotropic antenna (i.e., radiating energy in all directions uniformly) with the same power input, and is dimensionless.

For plane waves, the power density (S) is related to electric field strength (E) and magnetic field strength (H) by the impedance of free space, i.e., 377 Ohms (Ω), as in Equation 3.

Equation 3

$$\begin{aligned}\mathbf{S} &= E^2/377 \\ &= 377 \cdot H^2\end{aligned}$$

where

S is in units of watts per square meter
E is in units of volts per meter
H is in units of amperes per meter

Equation 4 is used where S in units of mW/cm^2 is desired.

Equation 4

$$\begin{aligned}\mathbf{S} &= E^2/ (377 \cdot 10) \\ &= 377 \cdot 10 \cdot H^2\end{aligned}$$

where S is in units of milliwatts per square meter, and E and H are as in Equation 3.

The start of the far field region, given by Equation 5, is where the antenna gain versus angular direction is independent of range for both the mainlobe and sidelobes of the antenna pattern. However, a well formed mainlobe can appear at ranges less than the range computed by Equation 5. In the near field, the power density estimated using Equation 2 overestimates the power density to some extent, particularly for phased-array radars.

Equation 5

$$\text{Far Field Range (m)} = \frac{2 \cdot (\text{antenna diameter (m)})^2}{\text{wavelength (m)}}$$

At distances less than those calculated using Equation 5, Equation 2 overestimates the power densities by an increasing amount as the distance to the antenna decreases. A generalized equation for calculating power density in the near field does not exist. Radar-specific models must be used to accurately estimate near field power densities.

N.4.3 Radars in the BMDS Program

The BMDS program radars operate within five different wavebands: UHF, L, S, C, and X bands. To streamline the evaluation of potential impacts to migrating birds, radars were evaluated based on the frequency that corresponds with the birds that might be maximally affected due to the resonant frequencies as indicated in Exhibit N-1.

For each of the five bands, the most powerful type of radar operating in that band was evaluated. Exhibit N-2 provides unclassified specifications on source power (both peak and average), beam width, antenna diameter, wavelength, and antenna gain for the most powerful radar in each band. The representative radar from each band is Position and Velocity Extraction Phased Array Warning System (PAVE PAWS) for UHF, COBRA DANE for L-band, Aegis for S-band, MPS-36 for C-band, and Sea-Based X-Band Radar (SBX) for X-band.

Exhibit N-2. Unclassified Specifications for Radars Used by MDA

Radar Antenna Type	Frequency	Peak Power (kW)	Average Power (kW)	-3 dB Beam Width (deg)	Antenna Diameter (m)	Wave-length (cm)	Gain (dB)
		Upper Bound (all values approximate)					
Phased Array	X-band (8 to 12 GHz)	500 [a]	150 [a]	0.2 [a]	9 [a]	2.5 - 3.75	53.2
Dish	C-band (4 to 8 GHz)	2,500 [b]	6 [c]	0.4 [c]	10 [c]	4 - 8	51.7
Phased Array	S-band (2 to 4 GHz)	2,200 [a]	65 [a]	2.0 [a]	5 [a]	7.5 - 15	38.6
Phased Array	L-band (1.22 – 1.25 GHz)	15,500 [c]	1,000 [c]	0.7 [a]	30 [c]	23 - 25	49.5
Phased Array	UHF (420-450 MHz)	582 [d]	146 [d]	2.2 [d]	22 [d]	67 - 71	38.0

[a] Technical Realities: An Analysis of the 2004 Deployment of a U.S. National Missile Defense System, Union of Concerned Scientists, May 2004
[b] Range Instrumentation Handbook, Vandenberg Air Force Base, September 2000
[c] GMD Validation of Operational Concept, MDA, April 2002
[d] NMD Deployment Final EIS, Ballistic Missile Defense Organization, July 2000. Peak and average power as reported by MITRE (2000) are 543 and 136 kW, respectively.

The peak power is actually the root mean square (RMS) power over a single pulse period, while the average power is the power averaged over a longer interval of time, such as one second. Because the radar emissions are pulsed, with off periods during which the radar “listens” for the returning reflected beams, average power is always less than peak power. The longer the listening intervals compared with the radar emission, the lower the average power relative to peak power. Phased array radars can have duty cycles as high as 25 percent. The maximum antenna gain can be approximated by assuming a circular aperture and computing the gain from Equation 6 using the given antenna diameter, D.

Equation 6

$$\mathbf{G}_T = 4\,\pi\,(\pi\,D^2 / 4)/\lambda^2$$

N.5 Biological Effects

This section first discusses EMR dosimetry expressed as the SAR. It then discusses the derivation of current IEEE exposure limits recommended for humans and notes their applicability to migrating birds. This section concludes by examining studies of potential effects of tracking radars on migrating birds for evidence that lower levels of EMR could interfere with their orientation.

N.5.1 Absorption of EMR

SAR has been used to express EMR dosimetry for many years. SAR expresses the rate at which EMR energy is absorbed from the incident field in units of watts per kilogram of body weight. It is a function of a variety of parameters of the body, including size relative to the incident wavelength, shape, density, total mass, and orientation relative to the incident field (SAR is higher when the body is more perpendicular than parallel to an incident field). As noted in Section N.4.1 above, SAR is highest at resonant frequencies. For example, for an adult male human exposed to an incident power density of 10 W/m^2 (1 mW/cm^2), the average SAR will be highest at an exposure of 0.25 W/kg at a frequency near 70 MHz. For a rat exposed to that power density at that frequency, the average SAR would be only 0.0125 W/kg. The average SAR for rats is highest at frequencies near 700 MHz, where exposure to an incident power density of 10 W/m^2 (1 mW/cm^2) would result in an average SAR of 0.8 W/kg. For humans exposed to that power density at 700 MHz, the SAR is less than 0.04 W/kg.

SAR for different species of birds will be maximal at the resonant frequencies for their body size (or size of the head). Exhibit N-1 indicates which frequencies will be resonant frequencies for different types and sizes of birds.

N.5.2 Basis for IEEE Standard to Protect Humans from EMR Exposure

Table 1 in IEEE Standard C95.1, 1999 Edition (IEEE, 1999) presents the MPE limits for humans in occupational settings (i.e., controlled environments) for frequencies between 0.003 and 300,000 MHz, a revision and expansion of the IEEE Standard C95.1-1991. In the near field region, the MPE is best expressed as either the electric field strength (E) or the magnetic field strength (H). The plane-wave equivalent power density values also are presented for comparison. The MPEs for the IEEE Standard vary with frequency and are most stringent (lowest) in a range of frequencies (30 to 300 MHz) surrounding the resonant frequencies for humans, where the MPE is approximately 1 mW/cm^2 averaged over a six-minute period. The MPE is less stringent at both lower and higher frequencies (e.g., at frequencies between 3,000 and 300,000 MHz, the six-minute average MPE is 10 mW/cm^2).

These MPEs are consistent with the 1991 adopted SAR criterion of 4 W/kg, which was based on behavioral changes observed in laboratory rats due to thermal loading and an

applied safety factor of 10. The working SAR of 0.4 W/kg was reexamined by the Risk Assessment Working Group of the IEEE Standards Committee on Non-Ionizing Radiation Hazards in a comprehensive evaluation of the recent literature and found to be adequate for the 1999 Standard: "An extensive review of the literature revealed once again that the most sensitive measures of potentially harmful biological effects were based on the disruption of ongoing behavior associated with an increase of body temperature". (pg 22; IEEE, 1999) The Committee noted further that "The disruption of a highly demanding operant task is a statistically reliable endpoint that is associated with whole-body SARs in a narrow range between 3.2 and 8.4 W/kg, despite considerable differences in carrier frequency (400 MHz to 5.8 GHz), species (rodents to rhesus monkeys), and exposure parameters (near- and far field, multipath and planewave, CW- and pulse-modulated)." (pg 22; IEEE, 1999) The time-averaged power densities associated with those thresholds ranged from 8 to 140 mW/cm^2.

For exposures to pulsed EMR in the range of 0.1 to 300,000 MHz, the peak (temporal) value of the IEEE MPE in terms of the E field is 100 kV/m. (pg 8; IEEE, 1999) Using Equation 4, that translates into a peak power density (S) of 2,652,520 mW/cm^2.

$$
\begin{aligned}
\textbf{Peak S}\ (\mathrm{mW/cm^2}) &= E^2/3{,}770\ \Omega, \\
&= 100{,}000^2\ (\mathrm{V^2/m^2})/3{,}770\ \Omega \\
&= 2{,}652{,}520\ \mathrm{mW/cm^2}
\end{aligned}
$$

For exposures to pulsed EMR with pulse durations less than 100 milliseconds in the same frequency, the peak power density for a single pulse is given by the MPE (from Exhibit N-1, the E-field equivalent power density) multiplied by the averaging time in seconds and divided by 5 times the pulse width in seconds. (pg 8; IEEE, 1999)

Equation 7

$$\textbf{Peak MPE} = \text{MPE} \cdot \text{Averaging Time (sec)}/5 \cdot \text{Pulse width (sec)}$$

This limit provides a conservative MPE given some uncertainty associated with the value of the spatial peak SAR in short pulses of EMR, which might be as high as 20 times the spatially averaged SAR. Thus, where pulses are less than 100 milliseconds (0.1 sec) in duration, the MPE is reduced by a factor of five. (pg 28; IEEE, 1999) For example, assuming a six-minute MPE of 10 mW/cm^2 for an X-band frequency, the peak MPE allowed for a 100-millisecond pulsed EMR field would be calculated as:

$$
\begin{aligned}
\textbf{Peak MPE} &= 10\ \mathrm{mW/cm^2} \cdot 360{,}000\ \text{milliseconds}/(5 \cdot 100\ \text{milliseconds}) \\
&= 7{,}200\ \mathrm{mW/cm^2}
\end{aligned}
$$

For a 1-millisecond pulse, the corresponding peak MPE would be 720,000 mW/cm^2.

At frequencies below 100 kHz, other biological mechanisms become important (e.g., electro-stimulation of excitable cells), but those frequencies are well below those used for radars. To prevent burns from the higher frequency (including infrared) EMR at frequencies above 15,000 MHz (15 GHz), the averaging time for the exposure duration in the MPE is reduced from six minutes according to Equation 8.

Equation 8

$$\text{Averaging time for the MPE (in minutes)} = 616{,}000 / \text{frequency (in MHz)}^{1.2}$$

The highest frequency proposed for BMDS radars is in the X-band, or under 12,000 MHz. Thus, neither of these frequency extremes needs to be considered for migrating birds potentially exposed to BMDS radars beams.

N.5.3 Threshold for Effects in Birds

Given the wide range of animals and conditions used to establish the human exposure limits for EMR, it is safe to assume that the MPEs for humans are conservatively protective against thermally induced behavioral changes in birds. However, for this analysis those MPEs were modified in two ways. First, the lowest six-minute average MPE value of 1 mW/cm^2 set for the resonant frequencies for humans was applied to the higher resonant frequencies (shorter wavelengths) for birds (Exhibit N-1). Second, the safety factor of 10 was removed to extrapolate from rodents to humans for two reasons. The first reason is that the base SAR threshold of 4 W/kg is conservative in several ways.

- The endpoint for the threshold, behavioral disruption owing to increasing body temperature, will have no permanent physiological effects.
- The SAR threshold assumes the far field, E-polarized "worst case" exposure as the reference condition (the SAR decreases markedly for other polarizations).
- The SAR falls off markedly for frequencies different from resonance.

The second reason it was assumed that the safety factor of 10 does not need to be applied to the SAR of 4 W/kg is that birds have a greater ability to eliminate body heat through respiration (flow-through design) than do mammals, and migrants regularly incur and must dissipate excess metabolic heat during long-distance flights. For the pulsed EMR, the requirement to divide the appropriate time-averaged MPE by a factor of 5 was removed to account for spatial variation of pulsed EMR because of the smaller size of birds relative to humans.

Thus, without conducting a specific evaluation for birds, these considerations indicate that 10 mW/cm^2 averaged over six minutes (or higher power densities averaged over correspondingly shorter periods of time) is a conservative reference value to protect against possible behavioral effects during migration due to thermal heating. This is

consistent with, but slightly more conservative than, the value of 42 mW/cm^2 estimated as a threshold for thermal loading equivalent to 1 times the basal metabolic rate in the Aplomado falcon, and a range of power density thresholds for the same effect from 38 to 61 mW/cm^2 for birds ranging in size from warblers to birds up to 7.7 pounds in weight used in the 1993 EA.

N.5.4 Studies of Potential Effects of Tracking Radars on Orientation and Flight of Migrating Birds

For migratory birds, there is one additional behavioral effect of concern that is not relevant to mammals, which is the possibility that EMR from radars might interfere with navigation during migration for birds that use magnetic cues for orientation. Because many species of birds can use the static magnetic field of the Earth as one of their sensory cues for navigation, it is reasonable to consider whether the EM fields – oscillating, pulsed, or continuous – produced by radar beams might interfere with bird navigation. This concern is relevant to lower power densities than might be associated with actual thermal effects in birds.

Interest in possible reactions of migrating birds to radar beams dates back to the 1940s. Several investigators reported finding short-term deviations in the flight path of migratory birds in the vicinity of radar transmitters based on observations rather than experiments. (e.g., Poor, 1946; Drost, 1949; Knorr, 1954; Hild 1971) Others (e.g., Busnel et al., 1956) were unable to repeat some of these observations. Older laboratory experiments failed to demonstrate reactions of birds to the transmission of continuous waves (e.g., Kramer, 1951, at 52 MHz), but more recent laboratory tests have indicated that at least some avian species can detect pulsed radar signals. For example, Kreithen and Davis (1995) demonstrated physiological reactions of pigeons to pulsed signals in the range of 1.25 to 2.45 GHz, which corresponds to L- to S-band frequencies. More recent field studies have failed to demonstrate changes in bird orientation or migratory behavior in response to radar beams. (Bruderer et al. 1999)

An experimental field study by Bruderer et al. (1999) found no effect of former military radar on the orientation of migrating birds. This XBR of approximately 9 GHz, 100 to 150 kW peak pulse power, 60 to 100 W mean transmitted power, 0.3 millisecond pulse duration, 2,082 Hz pulse repetition frequency, and a 2.2 degree opening angle of the pencil beam, was used to track nocturnal migrants between sunrise and sunset. Bruderer et al. (1999) calculated that a pulse of 100 kW peak power for that radar produces a peak power density of approximately 400 W/m^2 (40 mW/cm^2) at a distance of 250 m from the source and 100 and 25 W/m^2 (10 and 2.5 mW/cm^2) at distances of 500 and 1,000 m from the source, respectively. In these experiments, the radar was used to track the birds for at least 60 seconds with three separate 20-second tracking periods (turned off and on to test for directional responses by the birds) at distances from the radar as close as 200 to 300 m. With one possible exception, the investigators were unable to detect changes in flight

path that might be due to the tracking radar beam. They found that for large migrating birds (e.g., raptors, herons, ducks) reactions were sometimes detected when the radar was aimed at them on approach at a short distance (i.e., 50 to 200 m), but in these cases, the birds may have been able to see the movement in the radar antenna. In contrast, when they used a bright light beam, the majority of birds shifted direction away from the light source and slowed in flight speed at distances up to 1 kilometer from the light source. The only obvious response to the tracking radar was observed in September 1974, when a flock of 21 grey herons (*Ardea cinerea*) flew at an altitude of approximately 1,000 m above the radar in a V formation. When the radar beam was aimed at the flock, the V-formation disintegrated, and the birds flew in horizontal circles for some time before gaining altitude and reforming the V at 1,300 m. This study, in essence, has identified an NOEL for an XBR tracking birds for 20 sec intervals for up to 60 sec at peak power densities up to 40 mW/cm^2. Thus, there is no evidence that the proposed six-minute threshold of 10 mW/cm^2 estimated in this assessment or the six-minute threshold of 42 mW/cm^2 estimated for the falcon in the 1993 EA, would be insufficient to protect against possible effects on birds' magnetic orientation during migration. Data are lacking, however, to evaluate possible effects for birds tracked by radar for between 60 sec and 6 minutes.

N.6 Exposure Assessment

Exposure of migrating birds to radar beams will depend both on the behavior of the birds and the motion and output of the radars. This section includes a brief overview of bird migration patterns, emphasizing altitude, flight speeds, and density of migrating birds. Attributes of the PAVE PAWS radar are provided to illustrate principles of the operation of phased-array radars. Available unclassified radar specification data were then used to estimate maximal exposure durations for birds flying through a BMDS radar beam in each of the five radar categories in Exhibit N-2. This section concludes with estimates of the maximum power densities that might be encountered by birds under both relatively clear weather conditions and poor weather conditions, when the birds may be forced to migrate at lower altitudes than usual.

N.6.1 Background Information on Migrating Birds

N.6.1.1 Migration Flyways

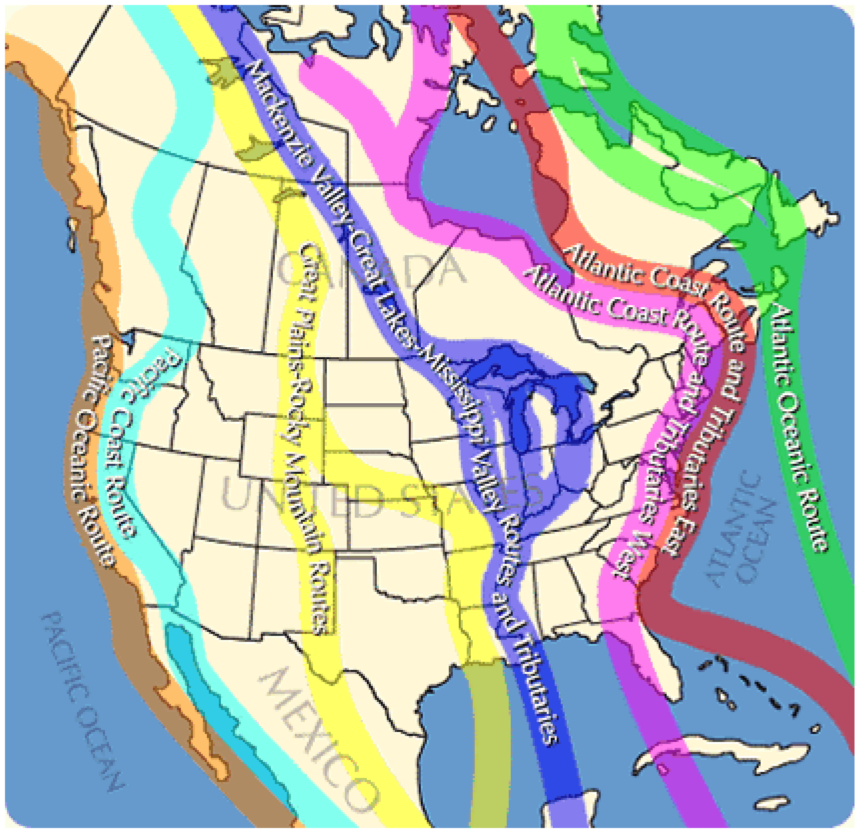
Bird migration generally refers to the movement of birds as they travel to and from their breeding and wintering grounds. The geographic paths that these birds travel are commonly known as migration routes. The migratory movements of most concern are the longer distance flights between North, Central and South America, and between Alaska and Asia, particularly by neotropical songbirds and some species of shorebirds, which have been experiencing population declines over the past several decades. The physiological strain of long-distance migration makes these birds particularly vulnerable to adverse events (e.g., storms) along the route.

Migration routes cover the entire North American continent and no two species follow exactly the same path. Migration routes tend to concentrate along coastlines, major river valleys, and mountain ranges. These broad, heavily traveled corridors comprised of many individual routes are called migration flyways. The concept of a flyway does not imply that all species migrate along definite paths or that all individuals within a species travel along the same route. Rather, flyways are a convenient generalization to help convey the idea that certain factors (e.g., geography, availability of food, etc.) guide the migration of birds along relatively regular paths. (Lincoln et. al., 1998)

Most bird species can navigate during migration using more than one type of cue depending on availability. Cues used by birds to navigate include visual cues (e.g., landmarks, polarization of light, location of setting sun, stars), sound (e.g., ocean waves on coastlines, other sources of infrasound), and 18 species of birds have been demonstrated to have a magnetic "compass" that is recalibrated periodically using other cues. (Wiltschko and Wiltschko, 1996; Hagstrum, 2000; Mouristen and Larsen, 2002; Cochran et al., 2004)

Migration flyways can be broken down into seven generalized routes for birds migrating in the fall from the U.S. to wintering grounds in the West Indies, Central America, and South America. Exhibit N-3 shows the principal migration routes from North America to wintering grounds. The same flyways are generally followed during spring migration, although many species return north over a different route than they used during fall migration. (Lincoln et. al., 1998) Exhibit N-4 describes the general characteristics of the major migration flyways in the U.S.

Exhibit N-3. Principal Migration Routes in North America



Source: Lincoln et. al., 1998

Exhibit N-4. Description of Migration Flyways

Route Name	General Characteristics
Atlantic Ocean	The Atlantic Ocean route passes over the Atlantic Ocean from northeastern Canada to mainland South America, with a stopover on the Lesser Antilles islands. This primarily oceanic route is used by shorebirds and seabirds, such as plovers, auks, and petrels.
Atlantic Coast	The Atlantic Coast route follows the Atlantic coast southward, passing over Florida, various Caribbean islands, and finally ending in South America. It is used by both land and sea birds. The western Atlantic Coast Route is a more direct coastal path to South America but involves much longer flights, and is used primarily by land birds.
Mississippi Valley	The Mississippi Valley route represents the longest migration route in the Western Hemisphere. It begins at the mouth of the Mackenzie River in Canada's Northwest Territories, passes over the Mississippi delta and across the Gulf of Mexico, and eventually ends in Argentina. The

Route Name	General Characteristics
	Mississippi Valley route is the preferred route for the majority of migratory bird species that pass through the U.S.
Great Plains-Rocky Mountains	The Great Plains-Rocky Mountains route also originates in the Mackenzie River delta and passes south through Alberta to western Montana. At this point, some birds move west to the Columbia River valley and then south to California. Other birds travel southeast across Wyoming or Colorado and then merge with Mississippi Valley route. Cranes, geese, pintails, and wigeons are the species most commonly found on the Great Plains-Rocky Mountain Routes.
Pacific Coast	The Pacific Coast Routes are the least heavily traveled migration paths in North America, beginning in western Alaska and continuing over the Gulf of Alaska to British Columbia. They then follow the coastline south, swing inland, and finally end in western Mexico. These routes are used primarily by geese, ducks, and arctic-breeding shorebirds.

N.6.1.2 Timing of Migration

Birds generally travel during two peak migratory seasons, fall and spring. Fall migration begins around late August and lasts until about early December. Spring migration generally occurs from March to May. (Birdnature.com, 2001)

During migration, some birds fly exclusively at night. The majority of nocturnal migrants are songbirds and other small birds. Radar observations have shown that nocturnal migration begins about an hour after sundown, reaches a maximum shortly before midnight, and then gradually declines until daybreak. (Lincoln et. al., 1998)
The day migrants include larger birds like ducks, geese, loons, cranes, gulls, pelicans, and hawks, and other smaller birds such as swallows and swifts. Soaring birds such as hawks, storks, and vultures can only migrate during the day because they depend on updrafts created either by thermal convection or the deflection of wind by topographic features like hills and mountain ridges. Birds that are able to feed at all hours, such as most water birds, migrate either by day or night. (Lincoln et. al., 1998)

N.6.1.3 Migration Altitude, Speed, and Flock Size

The altitude of migration is extremely variable and depends on factors such as species, location, geography, season, time of day, and weather. Nevertheless, some general conclusions about migration altitude can be drawn based on radar observations of migrating birds. Approximately 95 percent of birds migrate at altitudes under 10,000 ft. (Lincoln et al., 1998) According to the Clemson University Radar Ornithology Laboratory and the USFWS, the vast majority of birds migrate at altitudes between 500

and 4,500 ft, with the highest density of birds found at approximately 1,500 ft. (CUROL, 2005; Lincoln et. al., 1998)

Birds on long-distance flights fly at higher altitudes than short-distance migrants. Some shorebirds have been known travel at 15,000 to 20,000 ft over the ocean. Nocturnal migrants also fly slightly higher than diurnal migrants, but their altitude depends on the time of night. Birds generally gain maximum altitude shortly after sundown and maintain this peak until around midnight. Nocturnal migrants then gradually descend until daylight. (Lincoln et. al., 1998)

In general, migratory birds travel at air speeds of 20 to 50 miles per hour, with ducks and geese flying at 40 to 50 miles per hour, herons and hawks at speeds of 22 to 28 miles per hour, and flycatchers and smaller birds flying at 10 to 17 miles per hour. (Lincoln et al., 1998) In general, the northward spring flights are more direct and slightly faster than the southerly migrations in late summer and early fall.

A majority of bird species migrate in flocks numbering in the hundreds to hundreds of thousands. In general, many species breed over relatively large areas, but during migration, the population can be funneled through a more narrow area. For example, the eastern kingbirds summer breeding range extends 2,800 miles from Newfoundland to British Columbia; however, the width of the migratory path narrows to 400 miles from east-west at the latitude of the Yucatan. (Lincoln et al., 1998)

Several studies of bird migrations using NEXRAD (weather radar) have allowed researchers to estimate the density of migrating birds. (CUROL, 2005) Estimates of 120 to 230 birds per cubic kilometer (km^3) have been recorded for birds flying across the Gulf of Mexico in the spring. Densities of 230 to 490 birds per km^3 have been recorded over the Great Plains in the spring and fall. Densities as high as 500 birds per km^3 have been recorded over Houston, Texas. (CUROL, 2005) Dr. Sidney Gauthreau, the nation's leading expert on bird migration patterns using NEXRAD studies, indicated that the highest recorded density of migrating birds observed is approximately 2,000/km^3. This observation was made one evening during the first week of October above Clemson University in South Carolina after a cold front had passed through the area. (Gaurthreau, 2005) Similarly high densities, however, can be reached when flocks are initially taking off from a dense roosting site.

N.6.1.4 Migratory Bird Stopover Sites

Stopover sites are habitats or natural communities that consistently provide migrants with the necessary resources to refuel and rest during their journey. (NJAS, 2004) The following habitats typically provide the best resources and are therefore the most popular stopover sites for migrants.

Mountain Ridges

The forests along the slopes of mountain ridges typically provide important food resources like insects and fruit. (NJAS, 2004) Higher elevation sites along the slopes or tops of ridges are especially important in the fall, when insect populations peak. (Deinlein, 2005)

Riparian Areas

Major rivers typically support extensive wetlands and woodlands. The vegetation in these riparian areas provides concentrated food sources and sheltered resting areas for migrants. (NJAS, 2004) In the fall, foothill riparian areas provide important fruiting plants for birds such as tanagers and grosbeaks. (Deinlein, 2005) Throughout much of the arid western U.S., riparian forests are oases that offer the only trees to the landscape, and birds rely heavily on them for shelter. (Sterling, 2005)

Barrier Islands and Coastal Marshes

For many migrants, coastal woodlands and barrier islands represent the first opportunity to refuel after a long journey across a large body of water. For this reason, the northern Gulf coast contains many key stopover sites and hosts large numbers of migratory birds during the spring migration. (Deinlein, 2005)

Other key stopover sites, especially for shorebirds, are as follows: the Copper River Delta in southern Alaska; Gray's Harbor in Washington; the Bay of Fundy in Nova Scotia and New Brunswick; the Cheyenne Bottoms in Kansas; the Delaware Bayshore of New Jersey and Delaware; and the prairie pothole region of the northern U.S. and southern Canada. (Deinlein, 2005)

N.6.2 Operation of the PAVE PAWS Phased Array Radar

This section discusses the operation of one of the phased array radars that operates in the UHF frequency, the PAVE PAWS radar, as an example of the operation of radar used both to detect and track incoming missiles. There are three PAVE PAWS radars in the U.S. (Cape Cod, northern California, and Alaska). The PAVE PAWS radar operates at frequencies between 420 and 450 MHz.

Each PAVE PAWS radar is a two-faced phased array radar. Exhibit N-5 depicts the geometry for a single face of the PAVE PAWS radar. The PAVE PAWS phased array aperture is tilted backwards by twenty degrees with respect to the vertical. The array is able to scan a region 60 degrees on either side of the antenna center. Thus a single face of the PAVE PAWS radar can scan a range of 120 degrees (the azimuth).

Exhibit N-6 shows both faces of the PAVE PAWS radar that provides a total coverage of 240 degrees in azimuth. The orientation of the apertures in azimuth is site dependent. Exhibit N-7 shows the actual azimuth directions for each of the PAVE PAWS radars. The Clear, Alaska radar coverage is centered on North, while that of the Beale radar is West, and the Cape Cod radar is oriented East.

Exhibit N-5. Geometrical Orientation of PAVE PAWS Array Face

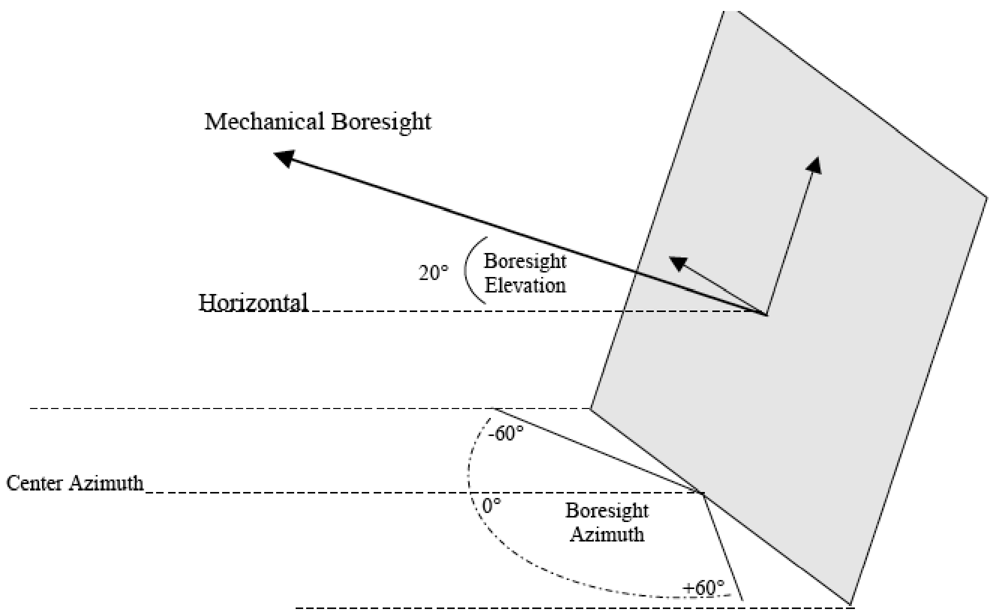

Exhibit N-6. Azimuth Spatial Coverage of PAVE PAWS Two Array Faces

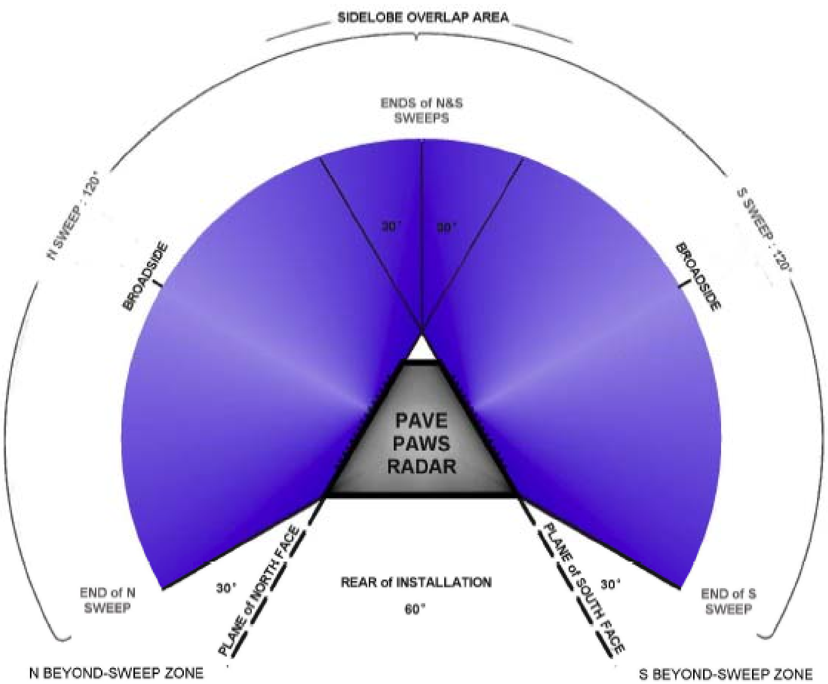

Exhibit N-7. PAVE PAWS Coverage Zones

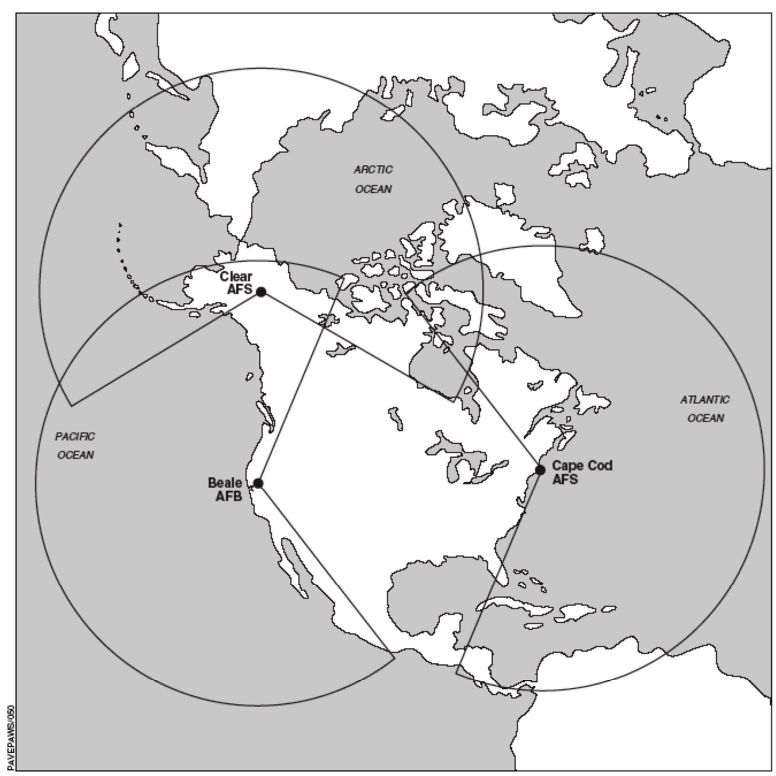


The PAVE PAWS radar has a maximum duty cycle of 25 percent with the surveillance function occupying 44 percent of the available transmit time. The tracking function occupies the remaining transmit time. The surveillance area for each radar face covers an elevation angle of three to ten degrees above horizontal and an azimuth angle of ± 120 degrees. The array face is tilted 20 degrees back from vertical so that each array scans from -17 to -10 degrees in elevation, with respect to the radar face, to provide the required elevation coverage.

In the far field, the main radar beam is more focused and narrow.[1] For the PAVE PAWS radar, approximately 60 percent of the energy is directed within an angle of 2.2 degrees (-3 dB beam width) (Ballistic Missile Defense Organization [BMDO], 2000), and approximately 90 percent of the energy is directed within an angle of 5 degrees (the -6 dB beam width; Figure 3 in MITRE, 2000). The remaining 10 percent of the energy is located in "sidelobes" where the transmitted waves do not completely cancel each other out. The maximum power density of the sidelobes is typically between 1/100 and 1/1000 of the main beam power density. (MITRE, 2000)

The scanning action of each radar beam occurs rapidly; the beam is redirected in azimuth and elevation on the order of tens of microseconds (μsec) to milliseconds. A pulse duration of 0.3 to 16 milliseconds is used, and the beam is off ("dwells") for approximately 10 to 50 milliseconds "listening for echoes." The beam is then redirected to another azimuth and elevation according to a predetermined schedule. Thus, the maximum duration of the radar beam in any one location is 16 milliseconds (0.016 sec).

The "instantaneous" beam intensity profile of the far field in terms of power density (in mW/cm^2) depends on the radar peak power, the antenna gain, and the distance from the radar. The maximum antenna gain at the center of the main beam in this case is 38.4 dB.

The width of the radar main beam depends on distance from the radar array and orientation of the main beam relative to the direction perpendicular to the antenna arrays. When the radar transmits a beam perpendicular to the radar array, it is said to be "looking at broadside," and when it is in this direction the radar beam is most tightly focused. As the beam is scanned up or down, left or right, from the broadside orientation, the beam widens.

The peak power of the PAVE PAWS radar is 582 kW, which the radar transmits at every energy pulse independent of the pulse width or the waveform. (MITRE, 2000) The average power varies depending on the transmitted pulse width and the length of the

---

[1] The distances to the beginning of the far field is calculated using Equation 5. With the diameter of the active antenna array equal to 22.1 m in this case and the wavelength equal to 0.69 m at center frequency, the nominal far field zone begins at 1,416 m (4,645 ft) for this radar. The distance to the far field reported in MITRE , 2000 was 2,322 ft and by Global Security (http://www.globalsecurity.org/space/systems/pavepaws.htm) is 1,440 ft.

listening period (during surveillance activities). The average power is the peak power multiplied by the fraction of the time that the transmitter is "on."

To determine the "worst case" long-time average power, it was assumed that the radar is operating at its maximum duty cycle (i.e., 25 percent of the duty cycle the transmitter is on, 75 percent of the time it is off, in the "listening" mode). All waveforms have the same peak power (in this case 582 kW). Thus, the maximum average power would be $582 \cdot 0.25 = 146$ kW. A worst-case average power density at the 1,000-ft fence of 0.012 W/cm^2 (12 mW/cm^2) was calculated based on the near field antenna patterns and an elevation of three degrees above horizontal, such that only EMR from the side lobes would reach a human standing on the ground at the fence line. (MITRE, 2000)

The average power density at 460 meters also was calculated in the main direction of the beam using the far field equation (Equation 2). An average source power of 146 kW equals 81.6 dB. Adding the antenna gain of 38.4 dB, the effective radiated power would be 120 dB, or 1,000,000 kW. Using Equation 2, at 460 m, the power density of the main beam would equal 33 mW/cm^2. Note that the far field actually begins at a further distance from the radar in this case. Thus, the value 33 mW/cm^2 somewhat overestimates the power density at 460 m.

N.6.3 Estimates of Exposure Duration

During surveillance tasks, the beam of a phased array radar system changes position every 10 to 100 milliseconds to scan the appropriate air space for potential incoming missiles. The actual duration of a single pulse is less than 16 milliseconds. Dish radars, which move the beam mechanically rather than by varying the phase of emissions from an array of radar antenna, move the beam more slowly when scanning. However, during target tracking tasks and during testing of these systems, the radar beam might be aimed in essentially a single direction. Thus, to estimate maximum possible exposure durations that might occur when testing target tracking functions, a stationary beam was assumed through which migrating birds fly. Exposure durations during surveillance tasks generally will be less than 0.02 seconds owing to the movement of the radar beam.

The -6 dB radar beam widths were used to estimate the maximum amount of time that a single migrating bird is likely to remain in a stationary main radar beam at varying distances from the radar. In Exhibit N-2, the width of a radar beam is specified in degrees, where 360 degrees equals a full circle. Thus, the width of the beam increases with increasing distance from the source. The duration of time a bird might spend flying through only the main beam was estimated. The -6 dB beam width contains approximately 90 percent of the energy emitted. The width of a radar beam for birds flying perpendicular to the direction of the beam at distances between 100 and 3,000 meters from the radar antenna was examined. The distance a bird would fly through a radar beam for birds flying parallel to the direction of the beam was also examined.

For birds flying perpendicular to the direction of the beam, the length of an arc in a beam intersecting an imaginary circle centered at the radar antenna is calculated at distance r from the radar antenna in Equation 9.

Equation 9

$$\mathbf{arc}\ (\mathrm{m}) = 2 \cdot \pi \cdot \mathbf{r} \cdot (\mathbf{w}/360)$$

where

r = radius or distance from the source (m)

w = beam width (degrees)

The calculations using Equation 9 are appropriate for the far field. In the near field the width of the beam was estimated using radar-specific models for the SBX (X-band), COBRA DANE (L-band), and PAVE PAWS (UHF) radars. For the C- and S-bands the analysis assumes that the minimum beam width is equal to the diameter of the radar antenna. Thus, as a conservative measure, Equation 9 was only used to estimate beam width when it resulted in wider arcs than the antenna diameter. The estimated beam widths are listed in Exhibit N-8 for each radar type.

The slowest moving migrants would spend the most time in a stationary radar beam; therefore, the time required for a small bird (e.g., warbler) flying at 10 mph (4.5 meters per second) to fly perpendicularly through a stationary beam at various distances from the radar was estimated, as shown in Exhibit N-9. Note that for the maximum beam width evaluated (2.2 degrees), a small bird could fly through the beam in about 47 seconds at a distance of 3,000 meters and in 2 to 15 seconds at a distance of 100 meters from the radar, where the power density of the beam would be much higher. For birds flying 20 to 40 mph, as do many migrant species, the exposure durations of the birds flying perpendicularly through a stationary radar beam would be one half to one quarter of the values listed in Exhibit N-9.

Exhibit N-8. Width of Main Radar Beam at Increasing Distance from the Source for Different Radars

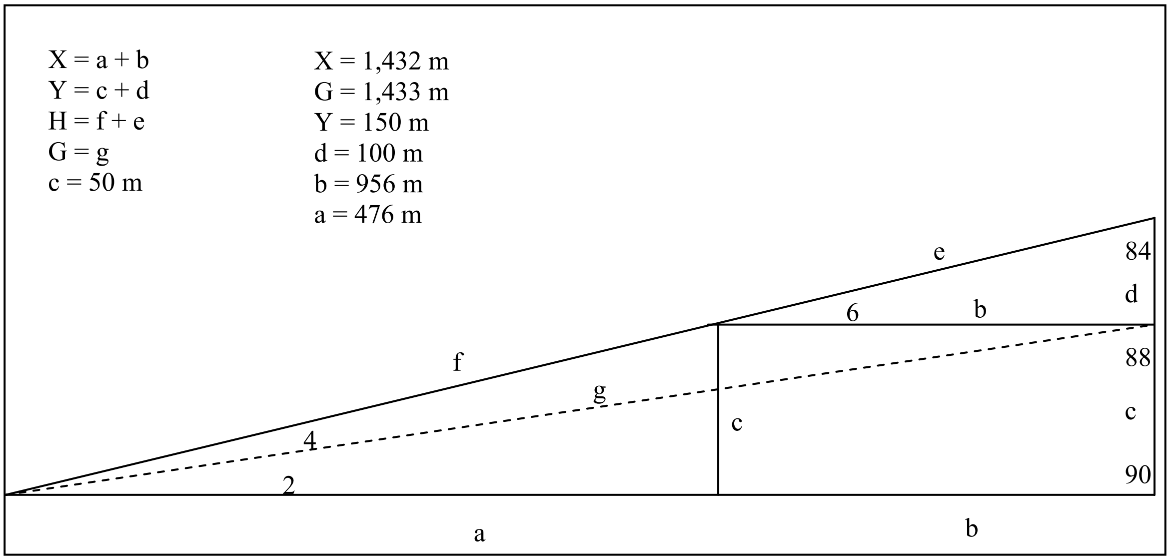
Radar Type	-3 dB Beam width (degrees)	Antenna Width (m)	Width of radar beam (m) with distance from a radar						
			100 m	300 m	500 m	700 m	900 m	1,500 m	3,000 m
X-band	0.2	9	65.9	108.0	117.8	109.4	124.2	115.0	115.4
C-band	0.4	10	10	10	10	10	12.6	20.9	41.9
S-band	2.0	5	7.0	21.0	34.9	48.9	62.9	104.8	209.5
L-band	0.7	30	59.9	57.0	65.9	64.4	62.6	46.0	64.4
UHF	2.2	22	40.4	27.6	36.8	39.9	47.8	71.8	131.5

Exhibit N-9. Maximum Duration of Flight Perpendicular to and Within a Stationary Main Radar Beam at Increasing Distance from the Radar for a Bird Flying 10 mph

Radar Type	-3 dB Beam width (degrees)	Flight duration (seconds) in main radar beam with distance from radar						
		100 m	300 m	500 m	700 m	900 m	1,500 m	3,000 m
X-band	0.2	14.7	24.2	26.4	24.5	27.8	25.7	25.8
C-band	0.4	2.2	2.2	2.2	2.2	2.8	4.7	9.4
S-band	2.0	1.6	4.7	7.8	10.9	14.1	23.4	46.9
L-band	0.7	13.4	12.8	14.7	14.4	14.0	10.3	14.4
UHF	2.2	9.0	6.2	8.2	8.9	10.7	16.1	29.4

For birds flying parallel to the radar beam, the distance the bird must cover to fly through the beam horizontally will be longer than for flight perpendicular to the radar beam. Thus, as the beam moves closer to horizontal, the longer a bird would be in the beam to fly through it horizontally. Exhibit N-10 analyzes a case where a radar that has a -6 dB beam width of 4 degrees is directed with an angular elevation of 4 degrees above horizontal (most proposed BMDS radars do not project less than 3 degrees above horizontal). We further assumed a worst case of the bird flying as low as an altitude of 50 meters above the height of the radar (e.g., as during bad weather), which would result in the bird flying through higher power densities than if the bird were flying at higher altitudes. Because in the far field, power density diminishes with the reciprocal of the square of the distance to the source (see Equation 2), whereas duration of a horizontal flight through the beam increases linearly with the distance from the source at which the bird intersects the beam, the highest risk to the bird will be the closest intersection with the beam, which occurs at the lowest altitude, assumed to be 50 m, relative to the altitude of the radar. In Exhibit N-10, the distance covered by a bird flying through such a radar beam is represented by line segment b. Line segment g (entire dashed line) represents the lower edge of the 4 degree radar beam, which would be 2 degrees above horizontal. Line H (line segments f plus e) represents the upper edge of the 4-degree radar beam, which is elevated 6 degrees above horizontal. Using the relationships depicted in Exhibit N-10, the bird would fly along a distance of 956 m to fly through this beam if it were stationary. A bird flying 4.5 m/sec (10 mph) could traverse 956 m in approximately 214 seconds, or 3.6 minutes. However, the power density associated with this flight would range between the power densities associated with a distance of 478 m (line segment f) to 1,422 m (line G) from the source.

Exhibit N-10. Side View of Radar Beam 4 Degrees in Width Elevated 4 Degrees from Horizontal



Thus, for stationary radar beams, the total time a bird is likely to be in the main beam will be a function of the beam's elevation, the altitude of the bird, and the air speed of the migrating bird. The power densities encountered will depend on the distance from the radar.

For moving radar beams, as during surveillance testing and operations, the maximum duration of an EMR pulse in one direction, and thus the maximum likely exposure duration for a given bird encountering a beam, would be on the order of milliseconds. Of the proposed BMDS radars, the PAVE PAWS has the longest pulse width of up to 16 milliseconds. Pulse widths for PAVE PAWS usually are less than that (as short as 0.3 millisecond), and pulse widths for other radars generally are 1 millisecond or less.

N.6.4 Estimates of Exposure Magnitude

The previous section demonstrated that exposure durations for birds migrating through an area in which BMDS radar is operating in a tracking or calibration mode such that the beam is stationary, are on the order of seconds to tens of seconds, even for the slowest migrants traveling at approximately 4.5 m/sec. Migrating bird exposure durations for radars in surveillance mode are likely to be no longer than 16 milliseconds and usually less than 1 millisecond. The analysis evaluates whether it is possible for some of the radars to be sufficiently powerful to exceed the power density thresholds described in Section N.5.3 for migratory birds flying at low altitudes and slow flying speeds.

The far field equation for calculating EMR power density (S) at a specified distance from a radar source was provided in Section N.4.1 (Equation 2). Because the duration of the

"on" pulse is generally under 0.01 to 0.001 sec and the duty cycle is less than 0.1 sec, it is most appropriate to use the average, not peak, power at the source to calculate average power densities that would apply to exposure durations of longer than 0.1 sec, as would be the case for birds flying through a stationary radar beam.

For birds flying at distances less than the far field from a radar, the power densities are less, and may be substantially less, than calculated using Equation 2. Therefore, near field power densities for the X-, L- and UHF bands were calculated using radar-specific models. For the C and S bands, Equation 2 was used for the near field power density calculations. Equation 5 is used to calculate the beginning of the far field region. For the X-, C-, S-, L- and UHF band radars described in Exhibit N-2, use of Equation 5 and the midpoint of the range of wavelengths listed indicate that the far field region begins at approximately 5,200; 3,300; 440; 7,600; and 1,400 meters, respectively.

Exhibit N-11 presents the power density results in mW/cm^2 for each radar type. In Exhibit N-11, the far field equation (Equation 2) was used to estimate power density, unless radar-specific near field power densities were calculated, which are italicized in Exhibit N-11. Radar-specific near field power densities were calculated because Equation 2 overestimates power densities in the near field. This effect can be observed for the 3,000 meter value for the XBR, which is substantially higher than all of the other X-band values. For the XBR 3,000 meters is still well within the near field region, which ends at 5,200 meters. Note that the reference power density of 10 mW/cm^2 identified in Section N.5.3 for use as a value indicating no impacts on migrating birds is associated with a six-minute averaging period. Higher power densities are allowed for correspondingly shorter periods of time, as will be discussed in Section N.7.

For comparison with the IEEE Standard c95.1-1999 peak power density limit of 2,652 W/cm^2, the peak power output for each radar (i.e., the power during the on phase) was also used to estimate peak power densities at varying distance from each radar type. Exhibit N-12 presents those results. The peak power densities in Exhibit N-12 were calculated using the same methods as in Exhibit N-11. The radar-specific near field power densities are in italics. Thus, Exhibit N-12 is a worst-case estimate of peak power densities with distance from the radar antenna.

Exhibit N-11. Average Power Density at Increasing Distance from the Source for Different Radars

Radar Type	Avg kW	Gain (dB)	Average power density (mW/cm^2) with distance from radar (m)

N.7 Impact Characterization and Mitigation

In this section, the exposures estimated in Section N.6 are compared with the reference values for assuming no impact discussed in Section N.5 to characterize potential impacts on a bird that does encounter a radar beam. The potential for population-level impacts are addressed by considering the likelihood that one or more birds in a migrating flock would actually encounter the radar beam. Both subsections N.7.1 and N.7.2 consider the key uncertainties in the estimates used to prepare this appendix and whether those uncertainties will tend to over- or underestimate risks. At the end of this section, recommended mitigation actions are provided for the radars that might, at certain times of the year, at certain locations, and under certain conditions of operation, pose risk to some birds.

N.7.1 Risks to Individual Migrating Birds

This section considers whether the reference values for no harm would be exceeded when a bird encounters a beam. This analysis was performed for each category of radar for a

variety of exposure durations and power densities. Specifically, four evaluations were performed: (1) the potential to exceed the IEEE Standard c95.1-1999 peak power density limit of 2,652 W/cm^2, (2) the potential for the average power density encountered from a stationary radar beam (e.g., tracking or calibration operations) to exceed the reference value of 10 mW/cm^2 averaged over six minutes, after adjusting for duration of exposure, (3), the potential for single 10 milliseconds pulse at peak power to result in an encounter that exceeds a relevant reference value, and (4) the potential for exposures from radars in surveillance mode to exceed the reference value of 10 mW/cm^2 averaged over six minutes.

N.7.1.1 Peak Power Density Limit

The peak power densities in Exhibit N-12 were calculated using the far field equation and radar-specific near field calculations. The peak power density values calculated within the near field using Equation 2 for the C- and S-bands are likely to overestimate the actual power density. Examination of Exhibit N-12 reveals that no birds encountering radar beams would be exposed to EMR that exceeds the IEEE Standard c95.1-1999 peak power density limit of 2,652 W/cm^2.

N.7.1.2 Average Power Density Limits

The reference value for this impact assessment for migrating birds is an average power density of 10 mW/cm^2 associated with a six-minute exposure period. The applicable power density for shorter exposures is higher. For this assessment, both the closest exposures to the highest power densities for birds flying across (perpendicular to) a radar beam and the longest exposures for birds flying along the direction of a near horizontal radar beam were evaluated.

For birds flying perpendicular to the radar beam, the exposure-duration estimates in Exhibit N-9 and the estimates of average power density presented in Exhibit N-11 are used to estimate risk. Exhibit N-13 lists the product of the exposure duration in Exhibit N-9 for a warbler flying 10 mph and the power density in Exhibit N-11 divided by the six-minute averaging time for each of the corresponding cells. The product of exposure duration and power density was divided by six-minutes to normalize the values to allow direct comparison with the 10 mW/cm^2 reference value that is averaged over six minutes. Exhibit N-13 values are in units of mW/cm^2. Where Exhibit N-13 values exceed 10 mW/cm^2, a bird at that distance from that type of radar could be exposed to more EMR than represented by the no-harm reference value.

Exhibit N-13. Average Power Density (mW/cm^2) Multiplied by Exposure Duration Divided by Six Minutes, with Increasing Distance from the Source for Different Types of Radar for Bird Flight Paths Perpendicular to the Radar Beam

Radar Type	Avg kW	Gain (dB)	Power density (mW/cm^2) multiplied by exposure duration (minutes) / six minutes						
			100 m	300 m	500 m	700 m	900 m	1,500 m	3,000 m
X-band	150	53.2	0.2	0.1	0.1	0.1	0.1	0.1	5.5
C-band	6	51.7	4.3	0.5	0.2	0.1	0.1	0.0	0.0
S-band	65	38.6	1.7	0.5	0.3	0.2	0.2	0.1	0.1
L-band	1000	49.5	5.1	5.4	4.6	4.8	4.9	8.2	4.8
UHF	146	38.0	0.1	0.1	0.1	0.1	0.3	0.1	0.1

Exhibit N-13 indicates that there is no concern for slow flying (10 mph) small birds, and thus there is no concern for faster flying larger birds, flying perpendicularly through any of the radar beams. Using the bird-specific six-minute reference values of 38 to 61 mW/cm^2 for birds ranging in size from warblers to 7.7 pounds in weight developed in the 1993 EA, none of the radars would pose a risk to migrating birds.

Note that the values presented in Exhibit N-13 represent a conservative assessment that may overestimate risks. An air speed of 10 mph was assumed for migrating warblers, the slowest of the migrating birds. Exhibit N-13 also assumes that the radar beam is stationary, which is approximately true for phased-array radars only when the radar is tracking targets or during calibration operations. For the dish radars operating in the C-band, mechanical movement of the radar will be slower, but for this radar, even the assumption of a stationary beam does not result in risks of exceeding the no-harm reference value of 10 mW/cm^2 (six-minute average).

Potential risks to birds flying in the direction of stationary beams elevated only 4 degrees above horizontal also was evaluated. For example, for birds flying at an altitude of 50 meters over an S-band radar with a 2.0 degree wide beam (Exhibit N-10), the estimated product of the average power density (between 478 and 1,433 meters; i.e., 9.3 mW/cm^2) and a 214-second exposure divided by six minutes, or 5.5 mW/cm^2, did not exceed our reference value of 10 mW/cm^2. Neither did the combinations of beam width and corresponding exposure duration calculated for altitudes of 50 meters above the X-band, C-band, and UHF radars using the relationships in Exhibit N-10 exceed the no-harm reference value for beam elevations between three and 90 degrees.

For the L-band radar, the reference value, 10 mW/cm^2, was exceeded at flight altitudes of less than 1,700 meters above the radar, when the beam is elevated between four and fifty degrees above horizontal. Exhibit N-14 shows how flight duration, average power

density, and the product of the power density and exposure duration divided by 6 minutes changes with increasing altitude of the bird above the antenna for the L-band radar (COBRA DANE), when the beam is 20 degrees above horizontal, which is when the beam is perpendicular to the radar face and is expected to have the highest power densities. Note that the closest horizontal distance in the right-hand column represents line segment "a" and the farthest horizontal distance represents line "X" in Exhibit N-10. For larger, faster flying birds the exposures would be less. For example, for birds flying 18 meters per second (40 mph) the maximum exposure would be 28 mW/cm^2, except for birds flying at an elevation of 100 meters with a radar beam at three degrees, who would have exposures of 42 mW/cm^2.

Exhibit N-14. L-Band Radar: Average Power Density (mW/cm^2) Multiplied by Exposure Duration Divided by 6 minutes, for Birds Flying Through a Stationary Radar Beam Elevated at 20 Degrees At Varying Altitudes Above the Radar

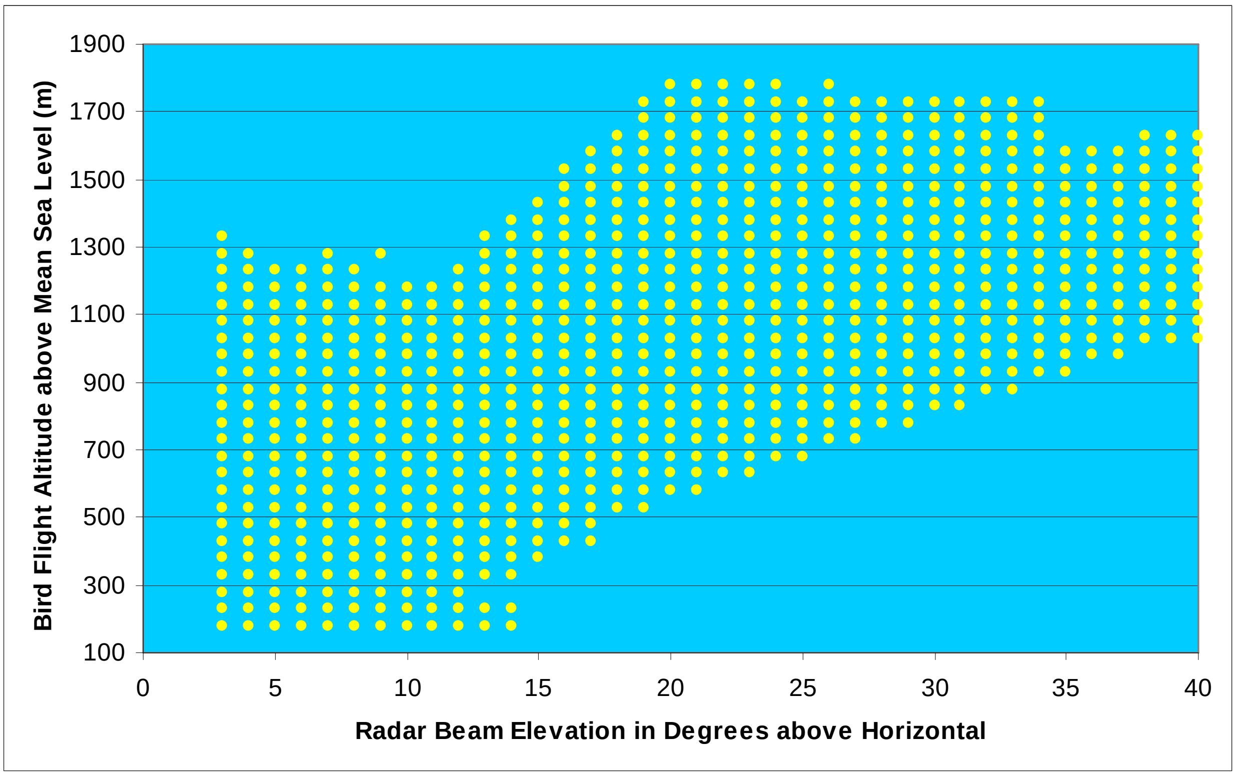
Bird Altitude Above Radar (m)	Flight Duration (T) (sec)	Avg. Power Density (S) (mW/cm^2)	(T · S)/360 sec (mW/cm^2)	Horizontal Distance from Radar (m)
200	20	115.3	6.3	560 - 610
400	20	152.3	8.3	1,130 – 1,210
600	28	278.0	21.7	1,700 – 1,820
800	37	206.3	21.4	2,260 – 2,420
1,000	47	129.2	16.8	2,830 – 3,030
1,200	56	90.1	14.1	3,390 – 3,630
1,400	65	66.3	12.1	3,960 – 4,240
1,600	75	50.1	10.4	4,530 – 4,840
1,700	80	39.5	8.7	4,810 – 5,140

Given the geometry depicted in Exhibit N-10, as the angle of the radar beam increases from 3 to 90 degrees above horizontal, the duration of exposure decreases as a bird begins to fly more perpendicularly to the radar beam. The magnitude of exposure, given by the power density, of the COBRA DANE radar beam changes non-uniformly in the near field as the radar beam moves from an elevation of 3 degrees to 90 degrees. Thus, the analysis shows that for the COBRA DANE radar, a flight altitude of 1,700 meters above the radar would represent a no-harm altitude. This maximum no harm flight altitude occurs when the beam elevation is between about 20 and 40 degrees above horizontal. The COBRA DANE radar face is tilted back 20 degrees from the vertical, thus these elevations represent zero to 20 degrees above the radar bore site.

The COBRA DANE radar is situated near the edge of a cliff 100 meters above sea level and is approximately 30 meters in height. Thus, birds flying at altitudes of less than 1,830 meters above sea level at that location might fly through a stationary beam from the COBRA DANE at levels exceeding the no-harm reference value, 10 mW/cm^2, averaged

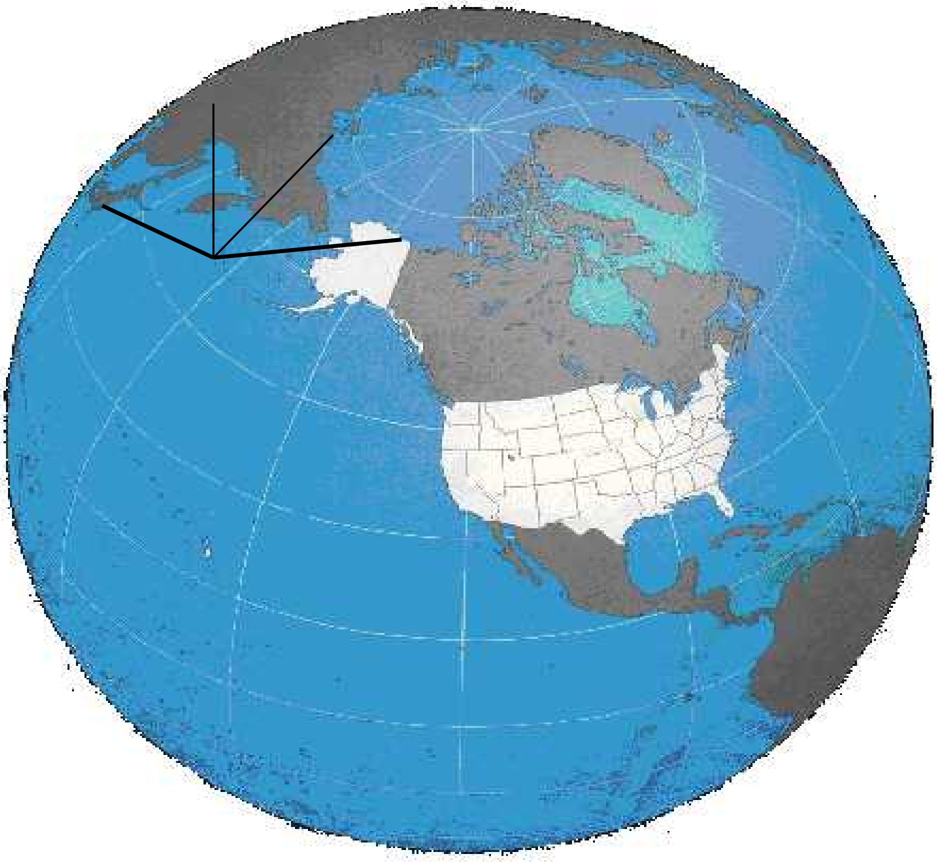
over six minutes. Exhibit N-15 shows the combinations of radar beam elevation and bird flight altitudes that may result in birds receiving exposures above the no-harm reference value of 10 mW/cm^2. Exhibit N-15 also shows that for beam elevations above about 15 degrees and for birds flying at altitudes less than 400 meters, the flight times through the radar beam are sufficiently short that the exposure is less than the no-harm reference value. Thus, at higher beam elevations and for lower flying birds, migrating birds flying parallel to the beam may not receive exposures above the no-harm reference value.

Exhibit N-15. COBRA DANE Radar Beam Elevation and Bird Flight Altitude Combinations Resulting in Exposures above 10 mW/cm^2



The assessment presented here is conservative. The analysis assumes that the birds will be flying directly into the radar beam, which is a worst case scenario. Some of the power densities in Exhibit N-14 are in the near field for the COBRA DANE radar, but were estimated using the far field Equation 2, and thus may overestimate the power densities likely to be encountered by a bird flying through the beam at the altitudes listed. Also, for lower beam elevations and higher bird flight altitudes the time for a bird to fly through the radar beam may be significantly longer than the radar beam would actually stay stationary. For beam elevations between 3 and 10 degrees above horizontal the flight times through the beam range from 40 seconds to 42 minutes. Exhibit N-16 shows the COBRA DANE radar scan area between the heavy lines as well as the high quality tracking area between the lighter lines. From Exhibit N-16, we can see that birds migrating from Alaska along the Pacific Oceanic migration route might fly parallel to the

Exhibit N-16. COBRA DANE Radar Beam Azimuth Coverage Area



radar beam for a portion of their flight. Also birds migrating from Alaska to Asia are likely to be flying more perpendicular to the radar beam than parallel to the beam. Thus the scenario presented above is a worst case, with birds flying only parallel to the radar beam. Migrating birds are more likely to be flying at an angle to the radar beam and thus there would only be a component of their flight that is parallel to the beam.

N.7.1.3 Single Pulse Exposures

This section presents an estimate of risks to birds that encounter a single beam pulse from a radar, and is appropriate to radars operating in the surveillance mode. After each pulse is emitted, the radar "listens" for returning echoes and then changes direction before emitting the next pulse. The chance of the direction change coinciding with the direction the bird is traveling is very small. Thus a bird would not encounter subsequent pulses. This assessment uses the estimates of peak power density at varying distances from the radar in Exhibit N-12. Exposure duration of 10 milliseconds was assumed as the emitted

pulse duration for each BMDS radar. This is a conservative estimate; most radars use pulse widths of 1 millisecond or less in most situations.

Exhibit N-17 shows the results of multiplying the peak power densities at the varying distances from the radar antenna (Exhibit N-12) by 0.010 sec pulse duration and dividing by 360 sec (six minutes). In Exhibit N-17, values less than the no-harm reference value of 10 mW/cm^2 indicate a negligible risk of impacting a bird encountering the beam at the specified distance. Exhibit N-17 indicates that there is negligible risk to individual birds encountering a single pulse of a radar beam.

Exhibit N-17. Peak Power Density (mW/cm^2) Multiplied by Exposure Duration (0.010 seconds) Divided by 360 seconds, with Increasing Distance from the Antenna for Different Types of Radar

Radar Type	Peak kW	Gain (dB)	Peak power density (mW/cm^2) multiplied by 0.010 sec / 360 sec						
			100 m	300 m	500 m	700 m	900 m	1,500 m	3,000 m
X-band	500	53.2	0	0	0	0	0	0	0
C-band	2,500	51.7	8	1	0.3	0.2	0.1	0	0
S-band	2,200	38.6	0.4	0	0	0	0	0	0
L-band	15,500	49.5	0	0	0	0	0	0	0
UHF	582	38.0	0	0	0	0	0	0	0

Note that the values presented in Exhibit N-17 represent conservative estimates, primarily because the far field equation (Equation 2) was used to estimate some of the near field power densities, which will be lower, possibly substantially lower. Second, a 10-millisecond pulse width was assumed, which overestimates pulse width (and therefore exposure duration) for most radars and most situations by an order of magnitude. Based on these conservative assumptions, it can be concluded that none of the radars (when operating in surveillance mode with the direction of the radar beam changing between pulses) are likely to pose a threat to migrating birds.

N.7.1.4 Radars in Surveillance Mode

This section evaluates whether birds flying in the surveillance zone for phased array radars, whose main function is surveillance, namely the PAVE PAWS and COBRA DANE radars, would experience exposures above the threshold of 10 mW/cm^2 averaged over six minutes. The X-band (SBX) radar is not evaluated because it is primarily a tracking radar and not a surveillance radar. The S-band radar is not evaluated because it does not impact birds in tracking operations where the radar beam is stationary, and thus will not impact birds during surveillance operations.

In the surveillance mode of the radar the surveillance zone is covered repetitively, and the surveillance pulses have longer pulse duration than for tracking. The analysis estimates the surveillance zone and beam area in steradians (solid angle measurement) to determine the number of beam positions required to cover the surveillance zone. A bird in the surveillance zone will be exposed to one beam dwell time per surveillance period. Thus the number of times a bird in the surveillance zone is exposed to the beam over a six minute period depends on the time to complete a survey of the entire surveillance zone.

For PAVE PAWS, the surveillance region is 240 degrees in azimuth and 3 to ten degrees in elevation or 0.508 steradians (= 240/360 2π (Sin (10) – Sin (3))). The PAVE PAWS beam width is approximately 0.0011 steradians, so that there are about 438 beam positions to be covered by the two radar faces. For COBRA DANE, the surveillance region is 120 degrees in azimuth and is assumed to be 3 to ten degrees in elevation or 0.254 steradians (= 120/360 2π (Sin (10) – Sin (3))). The assumed COBRA DANE beam width is 0.0003 steradians, so that there are about 835 beam positions to be covered.

The specific revisit time is dependent on the pulse duration assigned to each surveillance pulse. For the PAVE PAWS radar, assuming a pulse-duration of ten milliseconds, the eleven per cent duty time devoted to surveillance, and the use of two radar faces, the 438 beam positions would be covered in about 20 seconds. Thus, a bird flying through the surveillance zone would experience one pulse encounter every 20 seconds or 18 encounters every six minutes. Using similar assumptions for the single faced COBRA DANE radar for pulse duration and duty time, the surveillance zone would be covered in about 76 seconds. Thus, a bird flying through the surveillance zone would experience one pulse encounter every 76 seconds, or five encounters every six minutes.

Exhibit N-18 shows the results of these calculations. The results indicate that birds in the surveillance zones of the L-band or UHF band radars would not be exposed to EMR above the threshold of 10 mW/cm^2 average over six minutes while these radars are in the surveillance mode.

Exhibit N-18. Peak Power Density (mW/cm^2) Multiplied by the Number of Exposures in Six Minutes Divided by 360 seconds, with Increasing Distance from the Antenna for Different Types of Radar

Radar Type	Peak kW	Gain (dB)	Peak power density (mW/cm^2) with distance from radar (m)						
			100 m	300 m	500 m	700 m	900 m	1,500 m	3,000 m
L-band	15,500	49.5	0.1	0.1	0.1	0.1	0.1	0.3	0.1
UHF	582	38.0	0.01	0.01	0.01	0.01	0.02	0.01	0.00

N.7.2 Risks to Migratory Bird Populations

Sections N.7.1.3 and N.7.1.4 concluded that none of the radars proposed for the BMDS are likely to pose threats to migrating birds while operating in surveillance mode. However, it was not possible to exclude the possibility that a stationary radar beam, as might occur during tracking or calibration operations of the radars, might be hazardous to migrating birds crossing the beam (flying perpendicular to the beam) in the range of 1,400 to 1,700 meters of the COBRA DANE radar. For birds that might fly along the direction of a stationary beam from the COBRA DANE radar at altitudes of less than 1,830 meters (or less than 1,700 meters above the radar), the no-harm reference value might be exceeded. This section evaluates the likelihood that a flock of migrating birds flying by the COBRA DANE radar would be exposed to EMR above the no-harm reference value.

As indicated in Section N.6.1, most bird migration occurs between altitudes of 150 and 1,370 meters, with a majority of migrants flying around 460 meters, except during periods of poor weather when migrants may fly at altitudes of 50 or 100 to 300 meters or so. The calculations in Section N.7.1 indicate that risks of exposure to levels of EMR above the no-harm reference value near the COBRA DANE radar are likely during both good weather and poor weather when migrating birds are flying at lower altitudes. Section N.7.1.2 also showed that during poor weather, and thus lower migration altitudes, that some birds may fly “under” the COBRA DANE radar when its beam is at elevations of 15 degrees or more and not be exposed above the no-harm reference value.

There is unlikely to be population-level impacts on non-endangered bird species. If, however, the majority of migrants were to fly at altitudes of only a few hundred meters, as during periods of poor weather, with many possibly passing directly in front of the radar, and the radar beam is stationary, a majority of birds might be exposed to levels of EMR above the 10 mW/cm^2 reference level. That might have population-level effects on bird species or populations that are in decline.

The estimate of the number of birds that might be exposed to EMR above the no-harm reference value near the COBRA DANE radar are appropriate only to a limited set of conditions and are likely to be overestimates even for those conditions. First, it was assumed that all birds migrate at an altitude less than 500 meters. Second, the reference exposure density, 10 mW/cm^2 (six-minute average), is a conservative estimate of a threshold for possible adverse effects. Finally, this assessment assumes the radar beam is stationary.

For radars in surveillance mode, the sweeping motion of the radar beam may result in all birds flying in the surveillance area of the radar encountering the beam, but the exposure durations in this case are so short that the estimated risk of harm is negligible for all

radars when operating in the surveillance mode (see Exhibits N-16 and N-17 and accompanying text on conservative assumptions).

Thus, risks to migrating birds from radars for the proposed BMDS appear limited to the COBRA DANE radar and are limited to testing conditions when the radar beam might remain stationary for tens of seconds to several minutes (e.g., tracking a test target or during calibration). For the COBRA DANE radar, the risks are only to birds flying at altitudes less than 1,700 meters. None of the radars operating in surveillance mode are expected to pose risks to birds.

N.7.3 Mitigation Measures

The conservative analyses above indicate that the only radar type for which there is some risk in spring and fall to some migrating birds is the COBRA DANE, and the primary concern is for testing with the radar beam held stationary for some period of time (e.g., minutes). To mitigate possible risks to migrating birds, MDA should evaluate the possibility that the COBRA DANE radar might be tested with stationary beams during spring and fall migrations. If so, MDA should evaluate whether the locations where the COBRA DANE radar would be used are in a significant migratory route or near to a migratory stopover, such that large migratory flocks might on occasion pass through the radar beam. If such a risk is deemed to exist, it would then be advisable for MDA to consider use of a local NEXRAD to help evaluate when large flocks might be in the vicinity of the radar so that the timing of a test does not coincide with particularly large flocks of birds flying close to the radar.
